Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," DEC. 28, 1900.

THE

ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOL. XXVI. (NEW SERIES.)

FROM JULY 6, 1900, TO DECEMBER 28, 1900.

LONDON:
Printed and Published for the Proprietor by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court, Fleet-street, E.C.

1900.

Digitized by Google

INDEX TO VOL. XXVI. (New Series.)

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 290) than the Notes and Business Notes, references to which are shown by light type (thus, 290).

A.

Accidents, etc., 140, 141, 145, 181, 211, 246, 247, 248, 285, 322, 326, 355, 358, 362, 399, 427, 464, 505, 579, 613, 645, 680, 715, 706, 752, 786, 798

Accumulators, etc.:
for Boats, 219
Efficiency of, 217
Electrolytic Cell, A New, 398
Fitz-Gerald, D. G., Review of Work by, 739
at Gloucester Works, 84
at Guernsey Works, 302
Lead, The, 184
at Leith Electricity Works, 222
Loofah, The, 470
Questions and Answers on, 243, 280, 456
for Ships, 794
Submerged, 400
Switch for, 615
for Traction, 76, 147, 400, 472, 507, 580, 795
Voltaic Cells, A. G. Dell, 158

Acetylene, 695, 758
Agencies, 104, 392, 393, 427, 465
Air Ships, 577, 794
Air Storage, 291
Alloys, Nature of, 401
Alternating-Current Switches, Sparking at, 149
Alternating-Currents, The Resistance Offered by Iron Conductors to, 741
Alternating Supply Works, Reduction of Light-Load Losses in, H. Boot, 13
Alternators, *see* DYNAMOS, ETC.
Aluminium, 136, 289, 397
American Coal Strike, 542
American Exhibition, 1, 544
American Patents, 721, 796, 880
Andrews, L., Connecting Service Cables, 526, 572
Andrews, L., Distribution of Electricity to Scattered Areas, 45
Appointments, 685; also see PERSONAL
Appointments Vacant, 31, 68, 104, 176, 212, 284, 320, 356, 428, 464, 500, 536, 571, 607, 644, 680, 715, 752, 788, 824, 860, 896, 924

Arc Lamps:
Alternate-Current, Carbons in, 722
Bremer, The, 192, 229, 267
New Alternating, 866
Questions and Answers on, 315, 782
Report on Photometric Value of, 201
Submarine, A, 455

Aron Meter Company's Paris Exhibit, 320
Arrangement of the Distributing Network, C. A Gillie, 764, 796, 834
Automatic Fire Alarms, 218
Automobiles, 1, 30, 37, 38, 39, 145, 181, 183, 321, 325 355, 361, 433, 485, 497, 505, 507, 542, 608, 616, 649, 651, 688, 703, 704, 725, 757, 822

B.

Bacterial Light, 543
Baily, Prof., A Lecture-Room Volt and Ammeter, 453

Balance-Sheets and Reports of Electricity Works:
Aberdeen Accounts, 388
Blackpool Tramroad Company, 244
Bristol Accounts, 205, 286
Bury, 71, 205
Cardiff Accounts, 633
Cheltenham, H. Kilgour, 908
Edinburgh Accounts, 557
Hampstead Accounts, 142, 429
Hastings Accounts, 142
Higgens, T. W. B., on Traction at Chelsea, 53
Leeds Accounts, 604
London County Council (Traction Report), 167
Manchester Accounts, 208
Nottingham Accounts, 107
Oldham Accounts, 460
St. Pancras Accounts, 346
Sheffield (Mr. Fedden's Report), 709
South Shields Accounts, 388
Sunderland, 70
Truro (F. H. Headley), 461
Tunbridge Wells Accounts, etc, 637
Yarmouth Accounts, 59

Ballistic Oscillometer, 826
Barker, J. H., A Combination Integrating Wattmeter and Maximum-Demand Indicator, 335
Barmen-Vohwinkle Suspended Railway, The, 841, 873
Barnsley Electricity Works, 402
Battle of Systems, 219
Becquerel Rays, The, 472
Behrend, B. A., Factors which Determine the Design of Monophase and Polyphase Generators, 597, 670, 704, 727
Behr, F. J., Manchester and Liverpool Railway Brakes and Signals, 382
Binnie, Sir A., Address to Mechanical Section of British Association, 344
Black Electricians, 689
Blackpool and Fleetwood Tramroad, T. G. Lumb, 199
Boilers, Prevention of Scale in, E. D. Summerfield, 91
Boot, H., Electricity Supply for Lighting, etc., 453
Boot, H., Reduction of Light Load Losses in Alternating Supply Works, 13
Bose, Prof. J. C, Similarity of Effect of Electrical Stimulus on Inorganic and Living Substances, 370
British Canals, 579
Bruges Harbour Works, 296
Buenos Ayres, Electric Lighting at, 585
Burglary, 105
Bury St. Edmunds Electricity Works, 618

C.

Cable Splicing, 505
Calculation Simplified, 737
Calorimeter for Measuring the Wetness of Steam, A New Form of, Prof. J. Goodman, 337
Capacity, An Adjustable, 111
Carbon, Electrochemical Equivalent of, 398
Carus-Wilson, Prof., Polyphase Electric Traction, 805, 843, 906

Catalogues, etc.:
Allgemeine Elektricitäts-Gesellschaft, 616
Ashmore, Benson, and Co., 356
Berghaus and Young, 888
Braulik, G., 588
British Thomson-Houston Company, 239, 320, 608, 753
British Westinghouse Company, 239, 321, 608, 644, 681
Brown, Boveri, and Co., 357
Campbell Gas-Engine Company, 608
Davies, Kent, and Stewart, 888
Edison and Swan Company, 32, 556
Electrical Company, 752
Electrical Transmission Company, 600
Fairbanks Company, 32
Ferranti, Limited, 361
Fowler, J., and Co., 32
General Electric Company, 238, 572, 608
Gibbs and Son, 681
Guthrie and Son, 357
Hall and Co., 572
Henley, W. T., 644
Improved Glow Lamp Company, 142
Johnson and Phillips, 465, 538
Ledward and Co., 177
Mather and Platt, 465
Morley Engineering Company, 608
Offord and Jennings, 889
Pond Machine Tool Company, 925
Poth and Co., 240
Reavell and Co., 178
Renewable Lamp Company, 538
Simplex Steel Conduit Company, 305
Spencer, J., 240, 644
Sunbeam Lamp Company, 588
Worthington Pumping Engine Company, 428

THE

ELECTRICAL ENGINEER.

No. 1, Vol. XXVI. LONDON, JULY 6, 1900. PRICE 3D.

NOTES.

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon, Sir James Crichton-Browne, treasurer and vice-president, in the chair, when the special thanks of the members were returned to Dr. Ludwig Mond for his donation of £150 to the fund for the promotion of experimental research at low temperatures.

German Electrical Exports.—From trade returns published in Germany recently we gather that the exports of electrical machinery from that country during February greatly exceeded those of the preceding month, the weight in machinery being some 630 tons, as against about 350 tons in January. Of this total the United Kingdom took 44 tons, as against 28 tons in January.

University Extension Lectures.—The Society for the Extension of University Teaching do not appear to be neglecting their work during the summer months, as arrangements are now being made for the autumn courses of lectures. Thus we notice that the society intend to give another course of free pioneer lectures in St. Pancras, and have asked for the use of the vestry hall for one night a week for 10 weeks for this purpose.

Telephone Calls.—The great success of the new installation at the exchange of the National Telephone Company at Bristol of what is known as the common or central battery system, has decided the company to add it to other exchanges throughout the country. This system does away with the call bell, its place being taken by an incandescent electric lamp instead of a number, as now in use on most telephone switchboards. By the new method of signalling, the mere act of the subscriber lifting his receiver off the hook indicates to the operator that he wishes to communicate with the exchange. The system is, we learn, to be at once introduced, so far as London is concerned, into the new exchanges at Kensington and London-wall.

Ecclesiastical Telephones.—The first introduction of the telephone into church in the Aberdeen district, in order that the deaf may hear what is being said, has just been made by the Rev. J. Ure, of the Woodside U.P. Church. The telephone, we learn, is fitted up so that it can communicate from the pulpit to any pew in the church. The apparatus was tried last Sunday for the first time, and proved very satisfactory. We certainly think that the small telephone receiver would be much preferable to persons hard of hearing than the old ear-trumpet, but we question if persons in such a condition would hear what was said in the telephone, or if this were loud enough to let them hear, if it would not distract the attention of those round who could hear well.

The Pan-American Exhibition.—Our friends across the water do not mean to suffer from want of electrical power at the Pan-American Exposition next year. They have, we learn, already made arrangements for the supply of some 4,000 h.p., in addition to the 5,000 already contracted for from the Niagara Falls. An auxiliary power-house is to be built outside the exhibition grounds, where electricity is to be generated with steam and gas, and this plant will supply energy in case of any failure in the Niagara supply. It is to be hoped that that portion of the Exhibition Committee who are to look after the electrical work will attend to the matter of the safety of the buildings if fuses burn out, and not arrange everything in favour of a fire, as is done in the great French Exhibition.

Lead-Poisoning.—On Thursday afternoon last week the question of the prevention of lead-poisoning in the Potteries occupied the attention of a drawing-room meeting at the house of Mrs. Asquith, in Cavendish-square. Amongst those who spoke on the matter was Dr. Lewis Jones, who is well known in connection with electrical treatment at St. Bartholomew's Hospital. He expressed the opinion that electrical treatment would do more, and do it more quickly, than drugs and medicine in cases of lead-poisoning. It must, however, be done systematically, and in an establishment properly equipped for the purpose. Amongst other speakers at the meeting were the Duchess of Sutherland, Lord Hugh Cecil, and Canon Gore, who all agreed that something must be done to combat the evil of lead-poisoning in connection with pottery-making.

Institution of Junior Engineers.—On Friday last the members of this institution visited the works of Messrs. Caird and Rayner, 777, Commercial-road, Limehouse, at which are manufactured evaporators, condensers, feed heaters, and pumps. Under the guidance of the manager and staff the members had fully explained to them the system of manufacture, erection, and testing employed. The motive power in the works is electricity, current being generated on the premises from a dynamo driven by a gas-engine, and a number of electric motors work sections of the shafting. The lighting is also carried out by electric incandescent lamps. We also note that on July 14 this institution is to pay a visit to Lord Rothschild's estate at Tring, to inspect electrical machinery and the Hon. Walter Rothschild's zoological museum, etc. The members will leave Euston by the 1.45 p.m. train.

The Recent Motor Tour.—The official report of the recent 1,000 miles' trial of motor vehicles promoted by the Automobile Club has just been issued by the committee of 15 experts connected with the mechanical engineering world, including Sir William Preece, Major H. C. L. Holden, Prof. C. Vernon Boys, and Mr. W. Worby Beaumont. Sixty-three vehicles started for the journey to Edinburgh and back—a distance of about 1,100 miles—49 of them covering the distance in 11 days. The report refers to the carriage owned by the Hon. C. S. Rolls, which ascended the first 8¼ miles of Snap Fell, a hill 10 miles long, and rising from 150ft. to 1,400ft. above the sea-level, at the rate of 27½ miles an hour. The remaining 1½ miles was composed of gradients varying from 1 in 10 to 1 in 17, and was covered at the rate of

Digitized by Google

17¾ miles an hour. Vehicles of considerably less power, the report further points out, ascended the hill with ease at speeds far in excess of the pace at which it could be ascended by a horse-drawn vehicle. Some 60,000 miles of motor travel, concludes the report, were accomplished without an accident caused by a motor vehicle occurring to other users of the road.

City and Guilds of London Institute.—The report of the Governors of the City and Guilds of London Institute for the year 1899, which was recently issued, contains some interesting information on the contentious question of the distinction between universities and technical schools. It gives a list of 11 students past and present who volunteered and were accepted for active service, while most of the men working the Marconi apparatus at the front are stated to be from the Finsbury and Central Colleges. Details are then given of the various classes number of students, etc., in the Central Technical College,' there being 211 students in the electrical engineering branch. The South London Technical Art School is next dealt with, after which comes King's College, of which particulars of grants and medals, etc., are given. The latter part of the volume is taken up with appendices giving a short history of the City and Guilds Institute; a report of the Central Technical College for the previous year; a report on the Technical College, Finsbury, for 1898-9; reports for the same period on the South London Art School and the Technological Examinations Department, and also on the Leather Trades School; and the address by Sir Douglas Fox on presenting the certificates and prizes of the institute on Feb. 15, 1900.

Meter Inspection.—The question of the official supervision and guarantee of electricity meters is, we learn, claiming considerable attention in Germany. It is sought to determine the permissible error corresponding to different loads in connection with such meters, and also to what extent they should be officially guaranteed or subjected to periodical inspection. In this connection an appeal has been made to manufacturers to obtain their opinions as to when it would be advisable to introduce compulsory standardisation of meters. The *Elektrotechnische Zeitschrift*, in a leading article, gives some interesting data with reference to the extent to which meters are employed in Germany. The figures are the result of careful enquiries; nine manufacturing firms, besides 950 central stations and private installations, having been appealed to for information. From the information so obtained it was estimated that on July 1, 1899, there were in Germany some 126,000 electricity meters, though 60,000 only of these were in actual use. The returns given by the manufacturers further proved that the increase in the number of meters employed amounted in 1898 alone to 20,000. With regard to compulsory standardisation, it would appear from the answers received that the manufacturers concerned would like this delayed as long as possible.

Vacuum Electroscope.—In a recent number of the *Elektrotechnische Zeitschrift* there appears a description of a vacuum electroscope which has been constructed for experimental purposes. The apparatus has the form of a pear about 4½in. in length, its top consisting of a hollow aluminium ball, which rests upon an aluminium wire welded into the glass. This wire projects into the interior of the electroscope, where it takes the form of a flat ribbon, to which the broad pendulum leaves are attached, these latter being of aluminium foil about ⅔in. long and ⅓in. broad. In the lower portion of the glass bulb are two platinum wires welded into the sides of the bulb very close together. Experiments with the instrument proved the vacuum to be a perfect insulator, and that delicate electrostatic effects might be obtained with it. The ordinary electroscope experiments succeeded when applied to the apparatus, though the heavy charges on the glass walls which occurred during these experiments had a disturbing influence. When the apparatus was observed in a dark room, no trace of luminosity was apparent in it during the occurrence of strong electrostatic effects. Discharges of electricity into a vacuum are therefore dark, from which it may be concluded that the phenomena of light are dependent upon the presence of material such as would be found in air.

The American Telephone Convention.—The subject which occupies considerable space in the issues of our American contemporaries just to hand is the Independent Telephone Convention, which was held in Cleveland, Ohio, on June 12, 13, and 14. The meeting took place in the Electric Building, the offices of the Cuyahoga Telephone Company. The president, Mr. J. M. Thomas, delivered his presidential address on the Wednesday, in which he stated that since the previous congress the American Bell Telephone Company had passed into the hands of the American Telephone and Telegraph Company. There were now about 2½ million telephones in operation in the United States, including the Bell and independent companies. He believed that at reasonable prices seven million would be used. The Bell Company were a long time creating a demand for telephones, but since the independent movement the demand had grown enormously. If the Bell Company had not been hampered by a short-sighted policy, they might have advanced to an impregnable position before the patents running out allowed the other companies to take the field. In a paper on "Toll-Line Traffic," Mr. J. B. Ware, of the Citizens' Telephone Company, said toll-line business was always larger than was anticipated, and always proved a good investment. He thought that air line distances should control toll rates between points more than 50 miles apart, inside which limit local rates should obtain. The length of conversation should be three minutes, and a clearing house should be established to settle toll fees. The Hon. Hugh Dougherty, on the subject of "Telephone Investments," stated that he thought the telephone completed the trinity of business necessities—namely, the mail, the telegraph, and telephone. Many other papers of an interesting nature were also read.

The Dublin Bill.—By the narrow majority of six the Dublin Electrical Bill has been thrown out on the third reading in the House of Commons. Our readers will remember that this Bill would have authorised an electric lighting company to compete in Dublin with the Corporation electric supply. The Bill was passed through committee chiefly on the grounds that the Dublin Corporation had been most negligent in providing electric light for would-be consumers in Dublin, and that the Corporation had shown itself incapable of efficiently managing its undertaking. We, therefore, agreed with the passage of the Bill, which was brought forward at a time when the Corporation had again shown evidences that it would amend its ways. The present decision in the House of Commons is practically a verdict that while the Corporation of Dublin has shown itself a serious defaulter in the past, it is to be given one other chance before being branded as the owner of the first municipal electric lighting undertaking against which competition had to be granted. Personally, we think that even now the competition would be beneficial both for the electric lighting consumers of Dublin and for the Corporation itself. The speeches made at the third reading of this Bill in the House of Commons are worthy of careful perusal. Thus Mr. Ritchie, who usually inclines to favour municipal authorities, stated that he could not believe that the Corporation of Dublin was so feeble as to

Digitized by Google

be unable to obtain money to carry out the obligations as regards electric lighting, while at the same time it was conducting its ordinary duties as a corporation. Looking at the matter from the standpoint of the interests of the consumers, he thought it advisable that the now defunct Bill should be carried. Those speakers who supported the Corporation did so largely from sentiment. We trust that the narrow shave which the Dublin Corporation has had will be a good lesson to those other municipal authorities who, owning provisional orders, are not working them, or are working them in a perfunctory way.

Telpherage.—We have received some leaflets from the Consolidated Telpherage Company, of New York. The object of the company is to provide automatic methods, by the use of electricity, for the quick and economical transportation of mails and other light material. Telpherage, we are informed, is divided into four classes—viz., electric overhead transportation by means of aerial cableways, electric tube dispatch, electric overhead tramrail, and automatic narrow-gauge railway. As to aerial telpherage, this means consists of an electrically-driven car running on wires erected on high poles. One of the chief characteristics of the aerial system of the company is what is called the unit system. After many trials this was selected as the most flexible, and the one which most successfully fulfilled the greatest number of conditions. The unit consists of the combination with a suspended car of a shaft rigidly fixed to the supporting wheels, and electric motors on each side of the wheels having their revolving armatures fixed rigidly on the shaft. These motors are combined with a frame which connects them together. A unit combined with the yoke, including a trailing wheel, constitutes a telpher truck, and is termed a single-unit telpher. Two units combined by the yoke are termed a double-unit telpher. There is no gearing machinery on these motors, any speed variations being made by changing the size of the driving wheel of the unit. The motors are iron-clad and waterproof. The electric tubular dispatch is another branch of telpherage, and consists of tubes, of various materials, in which are steel rails. On these run cars propelled by small motors, and a speed of 50 miles per hour is said to be obtainable. A complete block system is provided in the tubes, the cars being switched on to their proper rails automatically. It is also arranged that the aerial cars can be transferred from the overhead arrangement to the underground without disturbing the cargo. It is a pity that the term "telpherage" should be used to cover underground systems. The past experience of English engineers in the overhead work should serve the company well.

Science and Technics.—In the June number of the *Wisconsin Engineer* we notice an address, delivered by Mr. B. A. Berend, of the engineering school of the University of Wisconsin, on the above subject. Mr. Berend's experience in electrical matters was gained in Germany, and he has proved himself by his technical writings to have profited by the education afforded him by his own country. Now he is located in the States, and his views as to the shortcomings of the educational system of Germany and on the general relations between science and technical engineering are of great interest. In his address the author deplored the contempt for facts and observation which was rampant in all German universities in the beginning of the present century. We presume that, in order to be correct when speaking of Germany, we should say at the beginning of the last century. For instance, Liebig, the great chemist, deplored that he had been cheated out of two precious years of his life by listening to the aimless and purposeless teaching of Schelling. The outcome of this highly speculative school of teachers was that Germany did not play the part it should have done in the early days of electrical engineering, but the author shows that his country, recognising its deficiencies, has since made strenuous efforts to overcome the same, and has been most successful in these. He proceeds to refer to a number of German physicists who have done much to give real scientific instruction, and at the same to keep this instruction in touch with practical engineering. Naturally, Prof. Hertz is mentioned. Discussing the examination question, Mr. Berend favours the German practice of making the universities places at which students have the right to hear any lectures they choose, without any restrictions as to which they should attend, and without any competitive examinations. There are a certain number of students who might be made to do average work under a more severe discipline, but the students wishing to acquire information in any particular subject are not hampered by restrictions such as obtain in some English colleges. In the author's opinion, the great drawback of the German polytechnic institutes is the onesidedness of their various departments. While he believes in specialisation, he thinks that a more general view of other branches of science should be given. In this he holds that the combination of scientific, technical, and literary education as is done in the States is to be highly recommended.

Institution of Civil Engineers. — The visit of the American Society of Civil Engineers to accept the hospitality of the London institution duly commenced on Monday last, when Sir Douglas Fox, the president of the English institution, received the representatives of engineering from the States and Canada. In his speech Sir Douglas sympathised with the visitors on the sad occurrence at New York. During the last year or two this country had experienced much to make them serious, but there had been one bright rift in the cloud—namely, the sympathy and the hearty fellowship which had been shown them by the United States. If both stood together for what was right and true nothing could prevent that progress which all desired, and it was a great advantage that men of science could approach such questions with a calmer mind and more resolute determination to pull together than was generally displayed in the political world. Indeed, even on the Continent during the last few years there had existed a friendly feeling. He was addressing strong competitors, but competition was looked for, and he thought that they in this country would be able to learn something from their visitors, for the engineers of the United States and Great Britain would have a great deal to do with the future of the world. When the Queen had heard that the American engineers were coming over, her Majesty was kind enough to order that the palace and grounds of Windsor Castle should be thrown open to them on Tuesday afternoon. On Thursday they would be received at the Guildhall, and on Friday at Warwick Castle by the Countess of Warwick. Mr. J. F. Wallace (the president of the American Society of Engineers), Mr. Jesse M. Smith, and Colonel Haynes having acknowledged the welcome, the visitors partook of refreshment, and later listened to the presidential address at their thirty-second annual convention. At night the subject of the height of buildings was discussed. During the afternoon much interest was displayed in the telautograph, which was exhibited at work in the hall, the circuit being 200 miles. By means of this apparatus handwriting can be telegraphed, the sender merely writing his communication in his ordinary handwriting, at any speed, on a roll of paper 5in. wide attached to the instrument. The communication thus sent is reproduced instantly on a similar roll of paper

Digitized by Google

attached to a similar instrument at the other end of the line, whether ordinary writing, cipher, shorthand, etc. The Queen gave a personal welcome to the engineers on Tuesday at Windsor.

Fuse Wire.—The material used for fuse wire on various electric lighting circuits is still varied according to the opinion of the engineer in charge of the undertaking. Of the various materials which are employed, tin and copper are most usually found. The use of tin is said to be bad by those engineers who prefer to use copper wire, because the fuse cannot be depended on after a certain length of time has elapsed. The opposite school, on the other hand, object to copper wire on the ground that it is necessary to run the same at a rather high temperature, unless a very large margin is allowed between the working load and the point at which the fuse blows. The real disadvantage of the tin fuse is, we believe, a mechanical one. The fuse wire is soft, and when screwed up it undergoes deformation. Unfortunately, this is not the only outcome of the softness of the material, and it seems from actual experience that with the slight expansions and contractions of the metallic parts of the fuse, due to the heat of the current in the fuse wire, the portion of the same under the terminal is gradually flattened still more until it is a loose fit. This causes more heating again, and in the end the fuse will blow at the terminal, and at a current often below the normal working current of the installation. The best way of overcoming this difficulty, and still retaining the advantages of the low melting point of the tin over that of the copper, is to provide heavy brass washers with a broad sawcut on one side of the same, into which the tin fuse wire can be soldered. These brass washers give a good connection with the terminal blocks, and also sufficient surface to prevent local heating The other method of avoiding the difficulty is to employ the copper fuse wire above referred to, and this is often done, but a molecular change seems to take place in these fuse wires in the course of time which renders it expedient for them to be inspected at intervals. We recently heard that one of the electrical officials of the Paris Exhibition was aghast at the fact that a copper wire could be used for a *plomb*. He argued that a *plomb* must be lead, and if a copper wire were used it would disorganise the whole system. We believe that this gentleman is still in charge of the Exhibition fuses, and we trust that he may not have to interview the fire insurance offices when the fuses under his charge set fire to the floors of the Exhibition.

Wiring Fireproof Buildings.—Mr. G. H. Jones gives in the *Wisconsin Engineer* some notes on electrical construction in fireproof buildings. He takes as his text the work carried out on the Merchants' Loan and Trust Building, Chicago. This building is a 12-storey one, occupying 18,000 square feet of ground space. The total floor area thus works out at about five acres. The electrical equipment of the building consists of some 5,000 16-c.p. lamps and 350 h.p. of motors, besides bells, telephones, watchmen's circuits, etc. The building is provided with two wire-shafts from the basement to the attic in the west portion, and one shaft from the third storey to the attic in the east portion. In these shafts the feeders and risers are run on porcelain insulators. At each floor-level the cables are fitted with split bushings, around which the flooring is to be laid. This transforms the cable-shafts into tiers of pockets, and overcomes the fire risk from open raceways. The wiring throughout, except the feeders and risers in the wire-shafts, is run in coricated iron conduits of standard gaspipe weights, there being over 12 miles of it used. The conduit is run as a complete iron-pipe job from cut-out cabinet to farthest light, each outlet being fitted with a cast-iron outlet box, into which the conduits are securely fastened by means of locknuts. The supply for the building is taken on the Edison three-wire system from the public mains, the voltage at the lamp terminals being 113. The motors are connected across the outside wires of the three-wire system at 230 volts. The electrical energy is distributed throughout the building by five lighting feeders and six power feeders, which emanate from a large distribution board at the basement. The lighting mains feed into sets of risers at central points, dividing the load equally. From these risers connections are taken off at each floor to supply current for main distributing centres located in the meter closets. All office floors are provided with two such closets, in which meters and cut-outs are placed, a meter loop being left for each office opening on a corridor. Each room has a separate circuit, even though there are only four or five lights on it. This gives great flexibility in case different offices are to be grouped together on one meter. The circuits terminate in cut-out cabinets made of sheet steel and having steel doors fitted with Yale locks. These cabinets are lined and faced with polished marble, which conceals wires and ends of conduits. All circuits are protected by Edison plug cut-outs, arranged so as to permit of their being grouped together as may be desired.

Tramway Profits.—In a paper read last Friday by Mr. C. H. Gadsby before the Tramways and Light Railways Association at the Agricultural Hall, the author stated that the problem of working tramways was to increase the gross receipts without unduly increasing working expenses. The first direction to which one would turn was naturally to increase gross receipts, and this increase might be effected by raising or reducing the fares according to circumstances, increasing the services, by better cars, better heating and lighting, better attention, and numerous other means; the increased service, however, being the one to which receipts responded most readily. To illustrate this the author gives a table showing the increase on a certain English steam tramway from this means, in this case the mileage being doubled in seven years, and the number of passengers and gross receipts being more than doubled, while working expenses had increased only about 70 per cent., giving a good net result. As to the receipts per car mile of tramway, these on British tramways varied from about 7d. to about 2s., but the author considered that for electric and cable lines any rise in receipts per car mile above 9d. should be at once checked by an increased mileage. In the case of horse tramways the limit should be 12d., and steam tramways 14d. or 15d. The author then gave a calculation to show that by increasing the mileage a larger clear profit could be made, while keeping down the receipts per car mile. Mr. Gadsby proceeds to give tables showing the average working expenses of horse, steam, and electric traction. With horse trams it appears the average total working expenses amount to 9½d. per car mile, those of steam 10¾d. per car mile, of which engine power costs 3½d. Taking the average working expenses of eight electric lines, the author works them out at between 5d. and 6d. per car mile, the cost of motive power being much lower. A table showing American experience with electric tramways agrees very closely with that of the English lines. The paper then contains remarks on the size of plant to be used, the wages and hours of tramway men, the time lost by both cars and men at the termini, etc. The author's conclusions are then given, these being: that it is generally possible by increased services to increase the gross receipts; that the operating expenses do not increase at the same rate as the mileage, and generally at a less rate than the receipts; that services

Digitized by Google

judiciously increased generally result in larger net profits; that electric traction constitutes the readiest means of increasing the receipts, and at the same time of reducing working expenses; and that on tramways already equipped in this country there is scope for reduction of operating expenses and increase of profits.

An Old Railway.—As will be gathered from our notice of the Swansea electric tramways, the British Electric Traction Company propose to commence at once to equip the Swansea and Mumbles Railway for electric driving. The history of this railway is unique, dating from 1804, when a Bill was brought before Parliament for the construction of a canal from Swansea to the Mumbles. We believe that at the last stage of this Bill it was deemed advisable by the promoters to include other means of transit than by water. The line was first equipped with stone rails, and was used principally for carrying limestone from the Mumbles to Swansea. Some idea of the value of the traffic on this line can be obtained from the following figures. In 1864 the line was sold for £20,000 to its present owners. In 1877 it was leased to the present tramway company for an annual rental of £1,500. In 1890 the Mumbles Railway Company agreed to pay the tramway company £1,000 per annum to forego this lease. Now we believe the tramway company has agreed to lease the line in perpetuity at a rental of £10,000. We need hardly say, after our personal examination of the line, that this rental is not justified by the present traffic. The line is now worked by steam engines drawing a train of from four to six coaches, according to the time of day and season of year. On bank holidays the rush is so great that the present plant is quite inadequate for the handling of the crowd which wishes to get to the fresh air of the Mumbles. For instance, on Whit Monday last over 25,000 people were carried, and we are informed (not by the tramway officials) that another 5,000 walked, because there was no chance of their hanging on to any unoccupied portion of the cars. With the present steam plant only 15 trains per day are run in each direction, which is equivalent to about one train per hour. As the district served is a residential one, private houses lying round the whole of the bay, it is obvious that this infrequent service is a great drawback, both for the line and the inhabitants of the district. It is this regular traffic which enables the line to earn dividends. If the line when equipped were to use the same large bogie cars as are now employed, and the train of six carriages were divided up into six trains of one carriage, a much more useful service would be obtained. We are confident, however, that the very fact of increasing the frequency of the service will multiply at least threefold the number of people travelling, particularly on the journeys to the stopping places in the middle of the line. In fact, we know of no line in which the conversion from steam to electricity offers greater advantages. As a physical connection will be made also between the line and the tramway system, a still further advantage will accrue. We trust that when we next visit Swansea it will be to see the inauguration of the electrical equipment of this Mumbles railway.

Modern Tramways.—At the Agricultural Hall last week, Mr. J. Young, manager of the Glasgow tramways, read a paper on "The Functions of Modern Tramways," specially referring to Glasgow. In this paper he stated that electric tramways have come as a godsend to those municipal bodies having to solve the housing problem. In the ordinary way electric cars were quite as safe as horse cars, and the Glasgow cars running on 60ft. well-jointed rails were as comfortable to travel in as could be desired. A car service must be regular, and at as short intervals as possible. As to the speed of the tramway car, that should depend on the power to control and stop it, and also on the nature of the traffic in the street. The maximum speed of eight miles per hour allowed by the Board of Trade was, he thought, too low for suburban traffic, although quite high enough on a crowded street. One great benefit of electric tramways was their economy of space, the horse space not being required. Coming to the work of the Glasgow Corporation, he stated that the tramways in that town dated from 1871, at which date the Corporation leased them for 23 years. In 1894 they proceeded to operate them as a municipal department, and when the extensions under the Glasgow Act of 1899 were completed he estimated that the system would extend to 121 miles of single track. The actual mileage would be a little over half of this, however, as the lines were almost all double. Of this 121 miles, 34 were outside the city boundary; and the population served by the Glasgow system was put down at 850,000. In 1896 a deputation was sent to Europe and America to report on electrical systems of tramways, and in 1898 a temporary power station for about 50 cars on the overhead trolley system was equipped. The success of the experimental line was so great, that after two months the Corporation decided to adopt the overhead system on the whole length of line. The scheme now being carried out makes provision for one central generating station and five sub-stations, and for eventually working 1,000 cars. The scheme was far advanced, and the Corporation expected to operate the bulk of the system at the time when the Glasgow International Exhibition was opened in May, 1901. The cars in Glasgow were only stopped at fixed stopping places, and a great traffic was created by means of halfpenny fares, the average distance for which fare was about half a mile. The lowering of the fares seemed to increase the net revenue. The number of passengers carried in 1894 5 was 57,000,000, and the receipts £222,000. In 1899 1900 these had increased to 127,600,000 and £465,000 respectively. Their experience with the small installation was that the total working expenses with electric traction were 6¼d. per car mile, as compared with 9d. with horse traction. There was, of course, interest on the greatly increased capital to provide for, but the saving in expenditure of 2d. per car mile was assured, and there was also a substantial gain in additional receipts. In fact, after deducting working expenses from gross receipts, the net revenue for the year ended May 31 last was 2·63d. per car mile with horse traction and 7·63d. with electric traction, a difference of 5d. per car mile in favour of electric traction. Next year, he thought, with the adoption of electric traction generally, the fares would be further reduced. In fact, the Tramway Committee had had before them for some time a proposal for next year to extend the ½d. stage, which would make the 1d. stage about three miles. The policy of the Glasgow Corporation was to carry the people at as low fares as possible, always keeping a safe margin for a reserve. They could not fall back on the ratepayers for any deficit. On the other hand, there was no attempt at relieving ordinary city rates with tramway profits The rates were imposed to pay for necessary work of various specific kinds performed for the community, and the work of each department was accounted for separately. Glasgow Corporation made its own gas, but did not, however, ask the consumers of gas to pay more than the cost of production in order to lessen the police, or sanitary, or any other rates. The same with the tramways; the benefits went to the users in cheaper fares and a better service.

THE SWANSEA TRAMWAYS.

The electrical tramways at Swansea, which were opened on Saturday last by the British Electric Traction Company, have had a very stormy history. The tramlines which are now converted to electric traction were originally laid down by the Swansea Improvement and Tramway Company. When the period of this company's Act was almost expired, the Swansea Corporation attempted to get the tramways into their own hands. For this purpose they brought a Bill before Parliament for the famous triple scheme, by which tramways, electric lighting, and refuse destruction were to be combined under one management. Numerous experts were called in on the question to confirm each other's reports, but, owing to some parliamentary formalities having been broken, the Bill was rejected. At the same time there was a Bill before Parliament for the conversion of the tramways to electrical driving promoted by the British Electric Traction Company, which had obtained a controlling interest in the Swansea tramways. As the Corporation Bill had failed, the company's Bill was allowed to pass, which gave a new life to the tramway undertaking in Swansea. In consequence of this, a complete reorganisation of the undertaking was commenced.

The next step taken by the tramway company was to apply for parliamentary powers to extend their tramways to the various outlying districts round Swansea. These extensions would, of course, be of great value to the inhabitants of these outlying districts, provided that the extension lines were equipped and run under one ownership with the old tramways. Here, however, the company was not successful, the opposition of the Corporation being so strong that the Bill was thrown out. Now the Corporation are themselves applying to the Light Railway Commissioners for powers to carry out practically the programme initiated by the company. What the success of this scheme will be it is difficult to say; but it seems to us that, even should the Corporation obtain the necessary powers, it would best serve the convenience of the public if the powers were afterwards leased to the company. If, then, an annual rental is asked for the right to construct these extensions, this rental becomes a direct tax on the users of the tramways, which is not to the advantage of the town and trade of Swansea.

The track now being used is entirely new, and it speaks volumes for the energy and organisation of the engineer responsible under the company for this work, Mr. Howard Smith, that this change was made without interrupting the horse tram service. The trams are now running over five miles three furlongs of route, connecting up Swansea, and of this some $2\frac{3}{4}$ miles is of single track. The equivalent length of single track is just over eight miles. The new rails are of the steel girder type, weighing 87lb. per yard. They were supplied by the Lorain Company, of America. The space in between the rails has been filled in with granite setts. Some parts of the routes were exceedingly hard on the horses, as on one section there is a half-mile of tramway with an average grade of 1 in 24. In this length a grade of 1 in 22 lasts for over a furlong. The curves, too, were severe, and these have been, where possible, improved by the company in reconstructing.

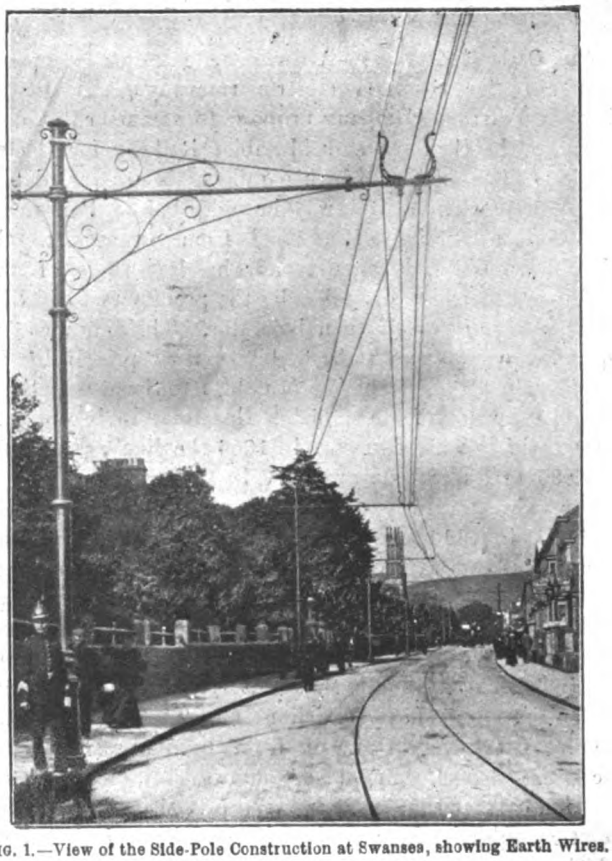

FIG. 1.—View of the Side-Pole Construction at Swansea, showing Earth Wires.

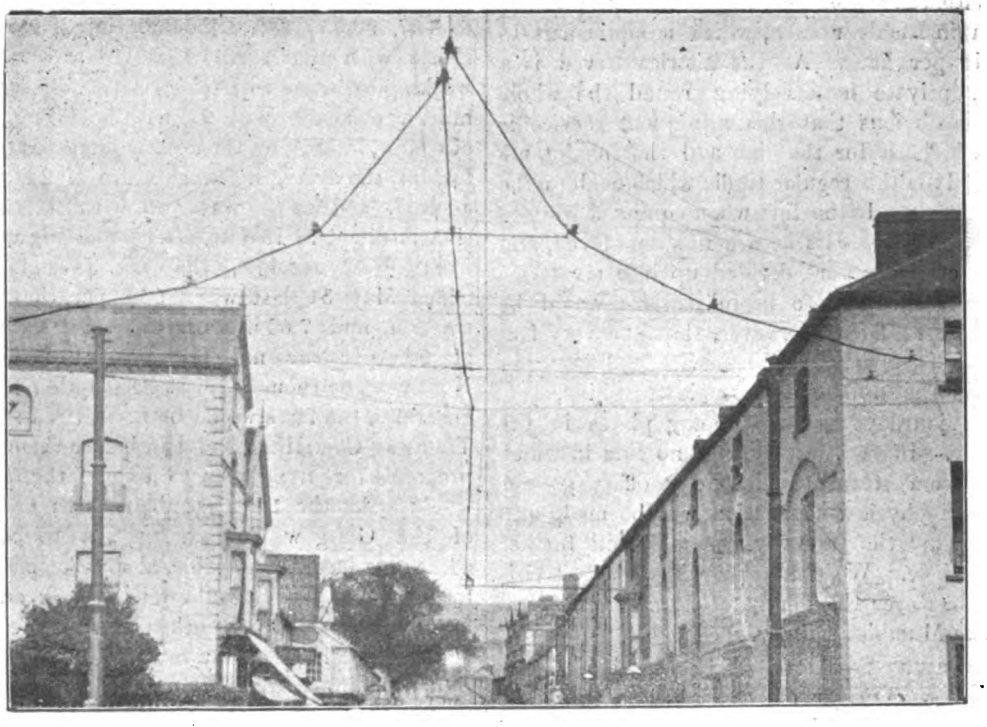

FIG. 2.—View of a Three-Way Switch in the Trolley Wire.

The whole of the overhead work was also carried out by the engineer to the British Traction Company, the materials being purchased from various well-known suppliers. In this

Digitized by Google

equipment both the side-pole and central-pole constructions are adopted, and the work, as inspected by us, shows evidence of great care in laying-out the positions of the poles for supporting the trolley wires. In our illustrations (Figs. 1 and 2) the reader will see examples of the overhead work, and also the means of supporting the guard wires. When passing under the railway bridges, a somewhat novel arrangement has been adopted to get over the need for asking leave of the railway company to attach the insulators to the trolley wires to the bridges. It is, of course, of the utmost importance that the insulation between the bridge and the trolley wire should be ample, and that the pressure of the trolley should not lift the wire against the iron bridge, causing a short-circuit to earth. To prevent this, long wooden troughs are supported under the bridges (as shown in Fig. 3) from the poles placed at each side of the bridge. In this way a good insulation is obtained, as well as a mechanical protection against any faults which may arise. In Fig. 2 is seen a three-way switch on the trolley wire, which is somewhat unique, as it is not often that three routes join at the one point.

The rolling-stock used on the line is not confined to one make either of car or motor equipment, and this enables the British Electric Company to conduct interesting trials as to the relative efficiency of the different equipments. Thus, on the Swansea tramways, no less than three different contractors have supplied motors. These contractors are the Brush Electrical Engineering Company, the British Thomson-Houston Company, and the British Westinghouse Company. The cars employed on the line just after the opening ceremony were of the single-truck type, and had only a single deck. The Brush Company have, however, supplied some large bogie cars, also single-deckers, which will be put in use shortly. These were being delivered at the time of our visit. Fig. 4 is a view of one of the smaller cars.

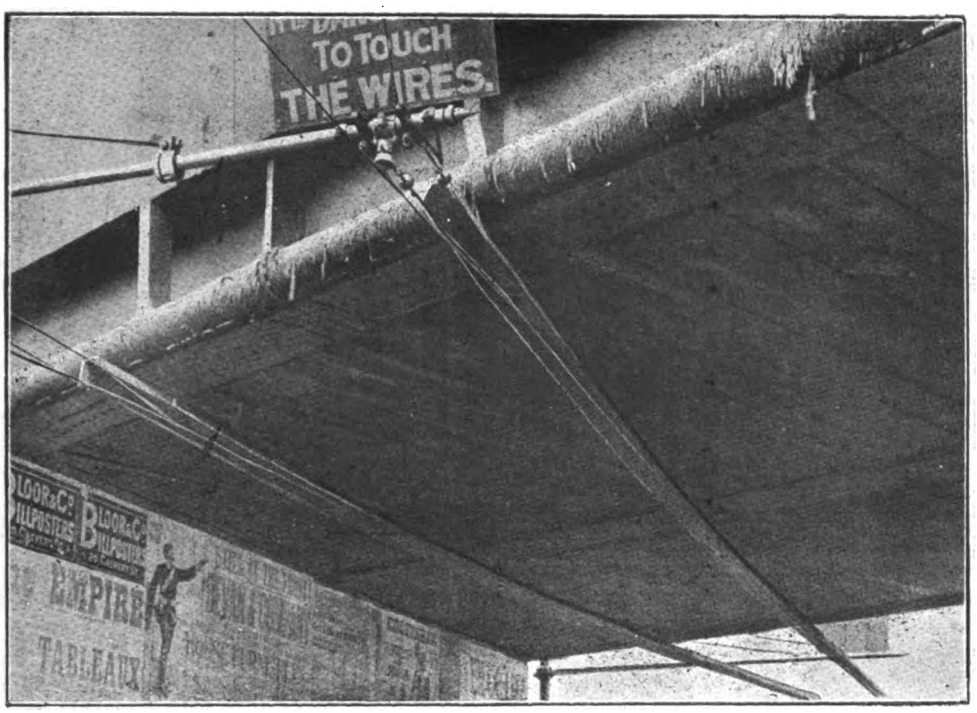

FIG. 3.—Method of Carrying the Trolley Wires under Railway Bridges adopted at Swansea.

Generating Station.—The electrical machinery for supplying the overhead line is placed at the tramway company's

Digitized by Google

depôt, which is near the shore of the bay. In these works there are at present installed two Ball and Wood engines, direct-coupled to two Westinghouse railway generators. The engine is capable of driving the dynamo when giving 200 kw. to the line, and running at 200 revolutions per minute, with a steam pressure of 150lb. The dynamos

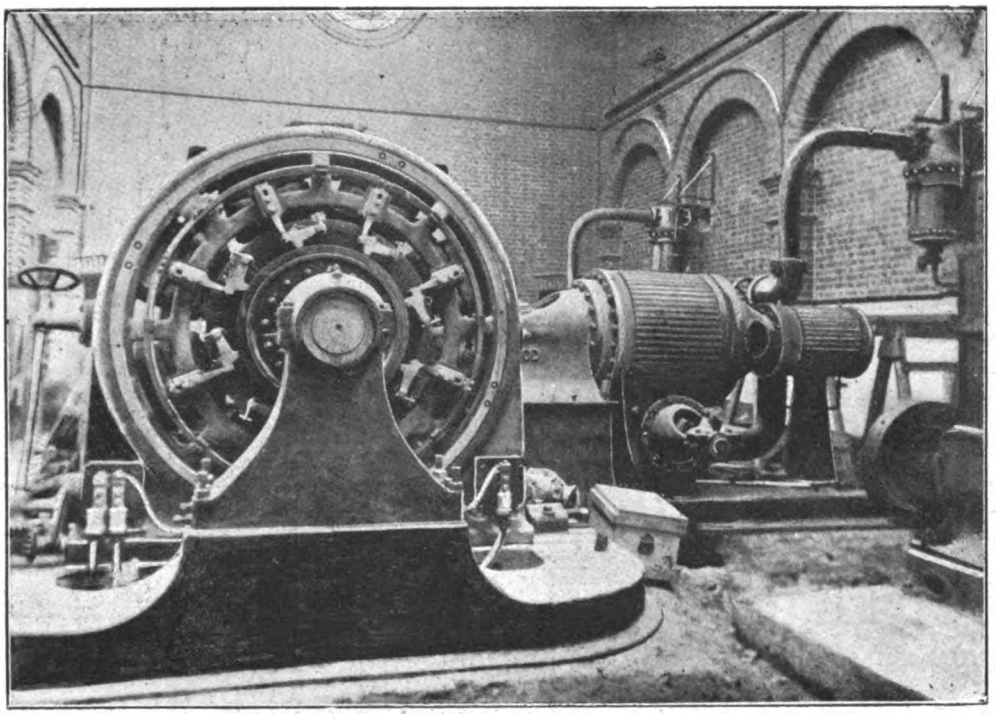

FIG. 5.—View of the Engine-Room, showing Westinghouse Generator and Ball and Wood Engine.

are 10-pole machines, as can be seen from Fig. 5, which gives a general view of the station. The arrangements of the machinery can be better seen from the plan and elevation of the station (Figs. 6 and 7). In addition to these two large dynamos, a smaller motor-

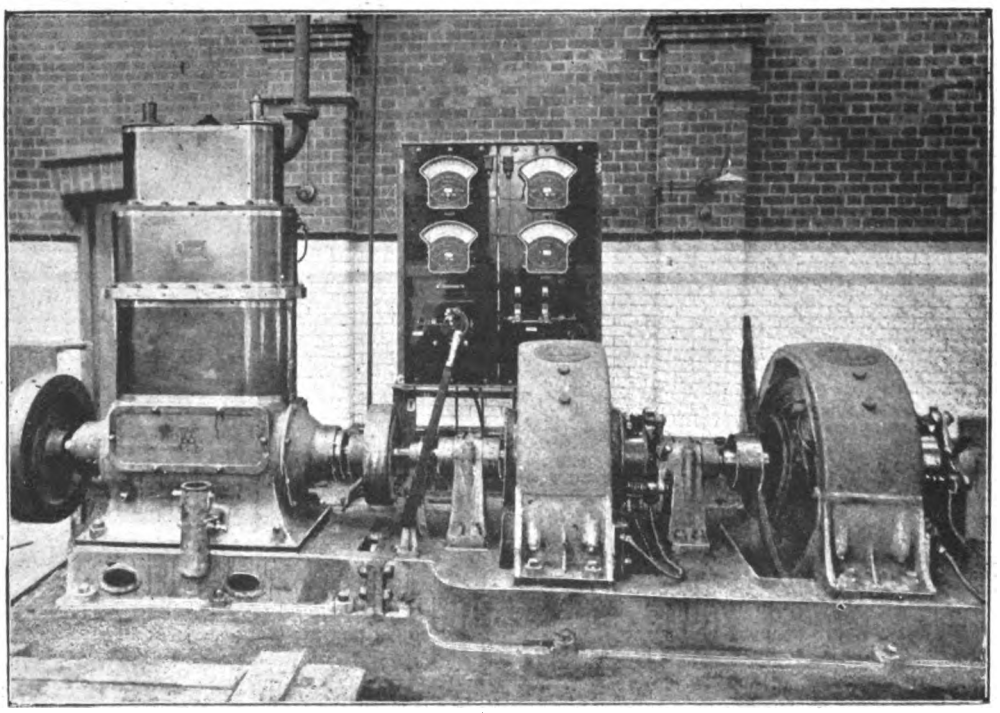

FIG. 8.—View of the Motor-Generator and Alley-Maclellan Engine.

generator (Fig. 8) is provided, together with an engine of the Alley-Maclellan type. The coupling between the engine and the spindle of the motor-generator is of the friction type, so that the engine can be uncoupled when it is required to run simply as a motor-generator. The speed of this set, which was supplied by the General Electric Company, of London and Manchester, is 450 revolutions per minute. In the ordinary way the motor in the combination is the 500-volt machine, which takes current from the 'bus bars. The other machine acts as a generator, and gives an output of 200 amperes at 100 volts. This 100-volt supply is used to drive the electric motors for the feed pump, air pump, circulating pump, and the other electric motors about the station. The station lights are also supplied at 100 volts. At night, when the large engines are shut down, by coupling the Alley-Maclellan engine to the motor-generator sufficient current can be obtained from the 500-volt machine running as a dynamo to bring home individual cars, while the 100-volt dynamo drives the accessories and lights the station. The next machine of which we have to make mention is the negative booster, which was also supplied by the General Electric Company, of London. This consists of an ordinary motor wound for 500 volts driving a booster which has a series field excited by the current passing through it to the positive

Digitized by Google

feeder. The return feeder goes through the armature circuit. In order to regulate the boosting voltage, a carbon shunt is provided across the series coils of this machine. Until the line is working fully it is difficult to say exactly what voltage will be required on this negative feeder, but the machine gives 28 volts when 165 amperes passes through the series coil. The switchboard is worthy of special notice, and although certain of the instruments are American, the rest of the board is thoroughly English, being supplied by the above-mentioned General Electric Company. The instruments on it are those usually used in traction work, and special care has been taken over the equipment of the instruments on the earth side which are required by the Board of Trade.

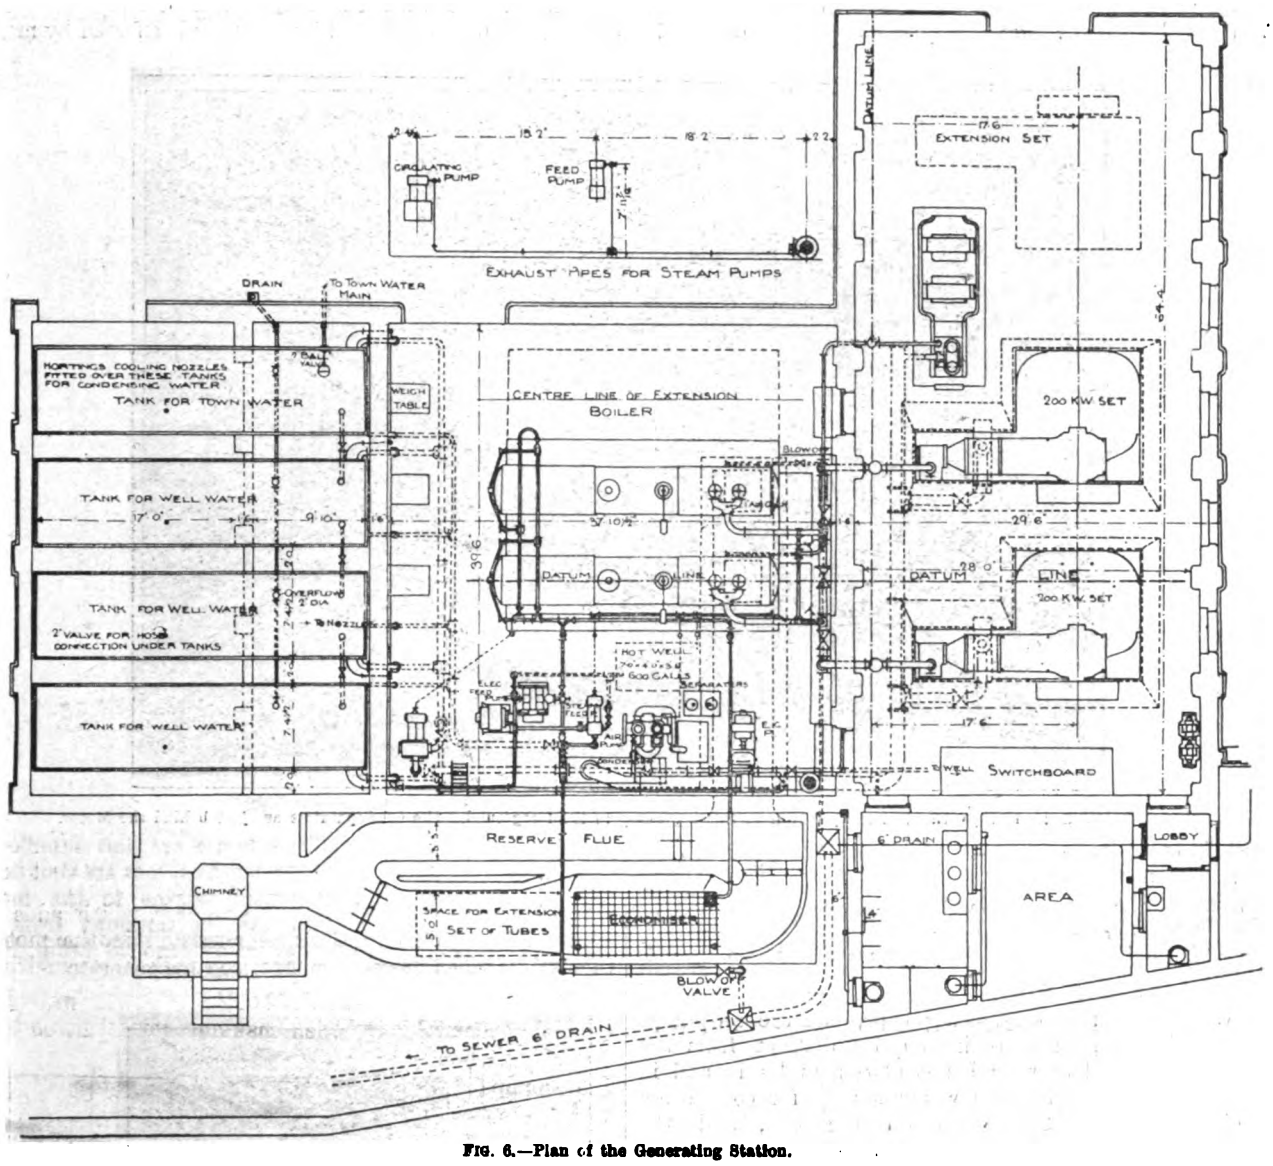

FIG. 6.—Plan of the Generating Station.

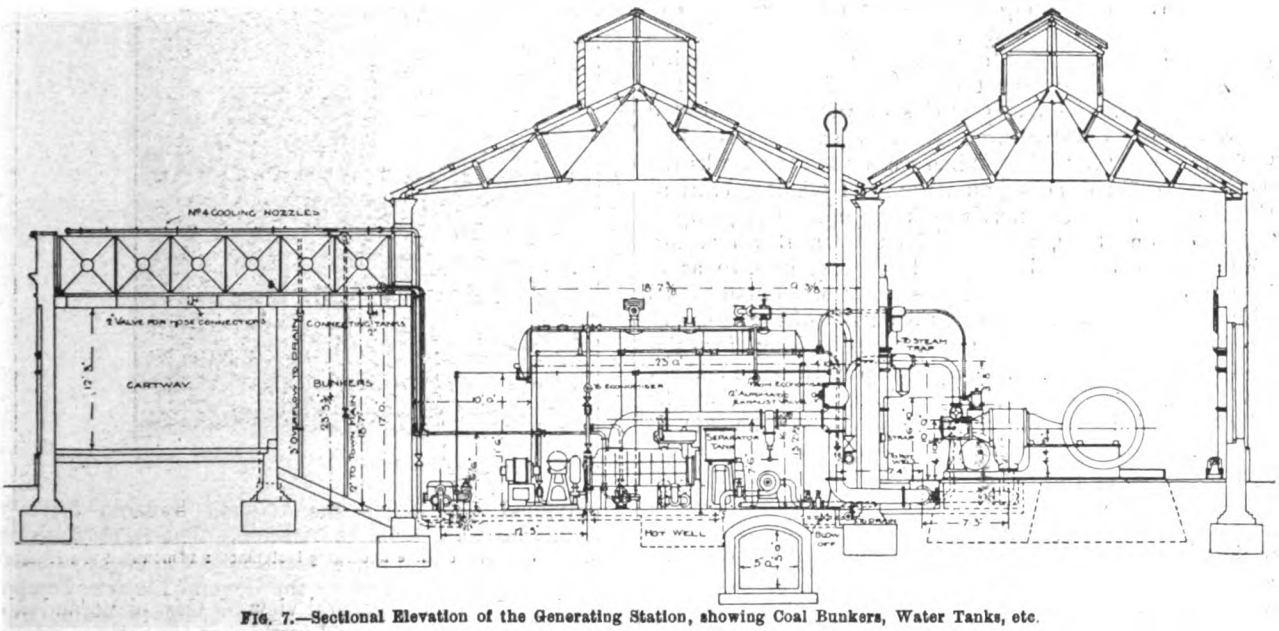

FIG. 7.—Sectional Elevation of the Generating Station, showing Coal Bunkers, Water Tanks, etc.

Three feeders are provided for on the switchboard—one going to the central part of the town, one to Morriston, and the other to the Cwm Bwrla route.

Boiler-Room.—The machinery in the boiler-room, and the arrangement of the boilers and tanks, are far in advance of those in other stations built by the British Electric Traction Company which it has been our privilege to inspect. As it will be seen from the drawing (Figs. 6 and 7), of the worm gearing driving the pump, is arranged on the principle of the well-known Hooke's universal joint.

When the station is in full work, it will be of great value to experiment with these electrical driving feed and circulating pumps to see if any saving is effected by means

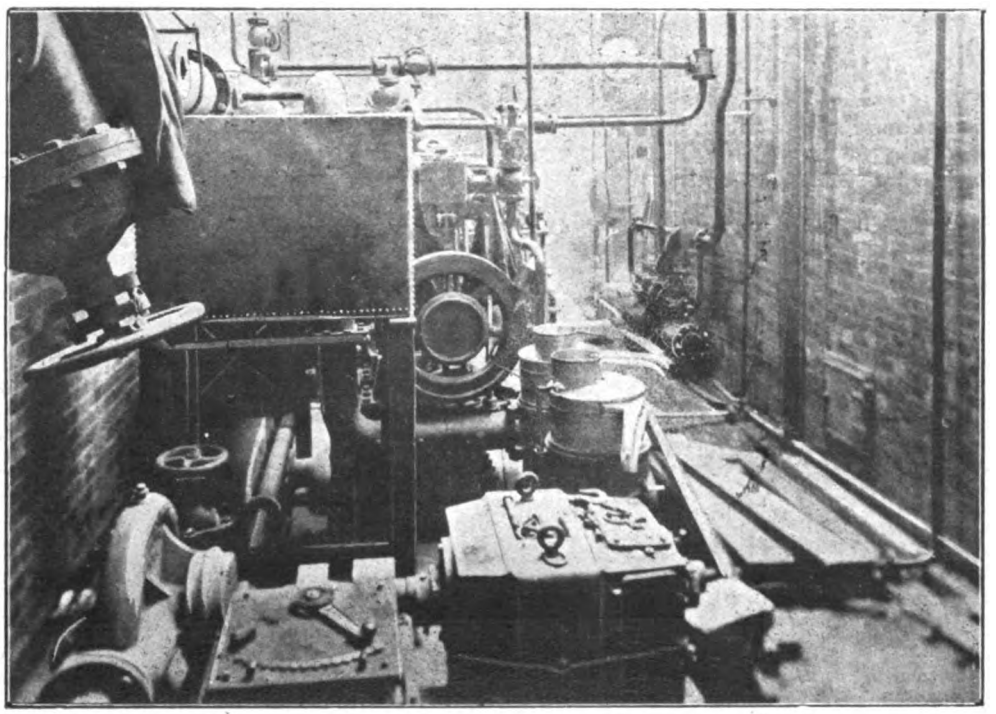

FIG. 9.—Condensing Plant, with Electrically-Driven Circulating Pump in the foreground. The Oil Separators are just behind the Motor.

Babcock-Wilcox boilers are used, and of these two at present are fixed. The coal is shot direct from the cart into the coal bunkers, the inclined floors of which bring it always within reach of the stoker. It is, however, to the condensing and boiler feeding arrangements that special attention has been paid. For instance, the condenser used is of the Wheeler surface condensing type, but the air-pumps and circulating pumps are kept quite distinct from the body of the condenser, and not placed under in and in combination as usual. The water supply for condensing is obtained from two wells on the site, and the town supply can also be taken in case of need. A large tank constructed over the bunkers serves as a reservoir for condensing the water, while a smaller tank at the other side contains the water reserved for feeding the boilers. The water is pumped out of the wells by means of a Blake-Knowles pump discharging into the overhead tank. The circulating water, after passing through the condenser, is sprayed up into the atmosphere from a number of nozzles distributed over the surface of the tank. The evaporation from the fine particles of water so projected upwards cools the water down to normal temperature before the drops reach the tank. When we visited the works the condenser was not going, on account of slight alterations being required to these nozzles. The circulating pump is of the Gwynne type, and is driven by a Brush motor. This motor is enclosed completely in cast iron, so as to render it quite dust and water proof; but we were surprised to see that the terminals were on the outside of the case, and that they were only insulated by a slight bushing of insulation from the cast-iron. It is a great pity that the makers do not design their enclosed motors in such a way that the cables can be led to terminals completely inside the case, so that no live metal is exposed. In fact, with this motor, as in the case of certain other English types of enclosed motors, sufficient care has not been paid to detail. The motor reminds one of an open-type machine with an irregular iron box round it. The water condensed in the Wheeler condenser is led to two separators of the dairy type, which, revolving at a high speed, completely separate out the oil from the water. Coming now to the feed pumps, we find that there is one steam feed pump and one three-throw Warren pump, which is driven by a Crompton enclosed motor. The connection between this motor and the axle of electricity. It must be remembered, however, in this case all the current which is passed into the motors is first transformed down in the motor-generator, which adds an appreciable amount to the power wasted in the motors themselves when making comparison with a steam-driven

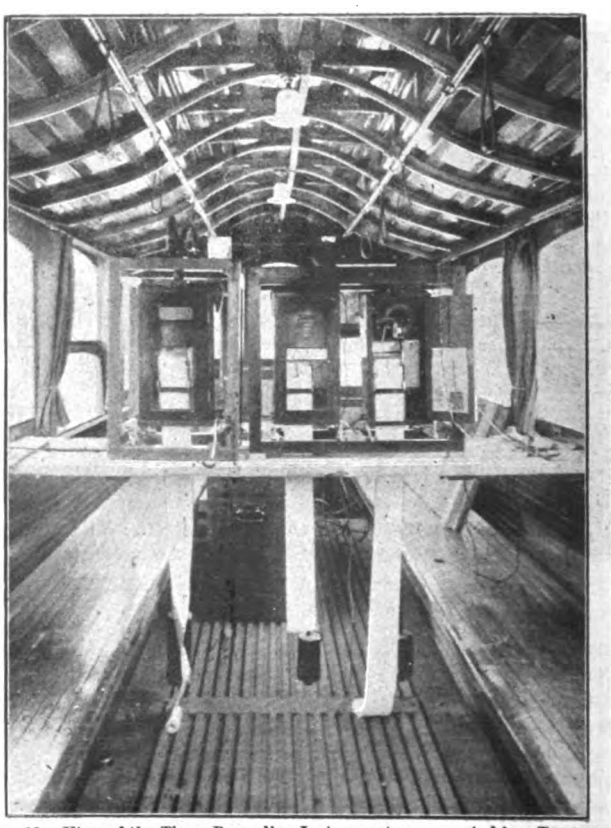

FIG. 10.—View of the Three Recording Instruments as mounted in a Tramcar.

set. Fig. 9 gives a general view of this plant and also of the cream separators used in this case for the extraction of the oil from the condensed water. The other general arrangements of the boiler-house plant can be well seen from Fig. 6. A weighbridge is placed near each boiler, so

Digitized by Google

that the quantity of coal taken for each can be found and recorded. A Green's economiser is placed in the main flue, so that hot feed water can be obtained. It will be noticed that this supply of current to the motors in the boiler-room is dependent on the motor-generator. A complete breakdown, however, is avoided by the provision of a steam feed pump, and, should an accident occur, the station could be worked non-condensing. This steam feed pump then could supply the boilers.

The car sheds are arranged in two distinct blocks in a straight line with each other, and between the two buildings a traverser will run, so that cars can be taken out of either shed without having always to traverse the full length of the sidings, or to take the first one that comes in the car-sheds. We may mention in this respect that there are two distinct entrances to the depôt from the lines in the street.

Referring, now, to the trials which the company are making on the various car equipments, these are being conducted for Mr. Sayers by Mr. S. Sudworth. For this purpose Mr. Sudworth has arranged three recording instruments, which can be conveniently mounted in any tramway. The way he supports these instruments is seen in Fig. 10. They are respectively a voltmeter, ammeter, and wattmeter. In order to prevent the vibration of the car from affecting the recording pen, an anti-vibration suspension has been obtained by means of indiarubber bands. Even these were found to be not sufficient to guard against the sudden jerks caused by rail joints and curves affecting the readings. Mr. Sudworth got over this by providing an iron tube at the base of each instrument, and attaching to the end of each tube a heavy lead weight. This weight gives the instrument a relief from vibration which could not be obtained in any other way. Our next illustration (Fig. 11) shows the curve traced by the ammeter for one portion of the Swansea tracks. These instruments, or rather the curves obtained by them, enables the engineers of the British Electric Traction Company to decide whether one type of car equipment has great advantages over another.

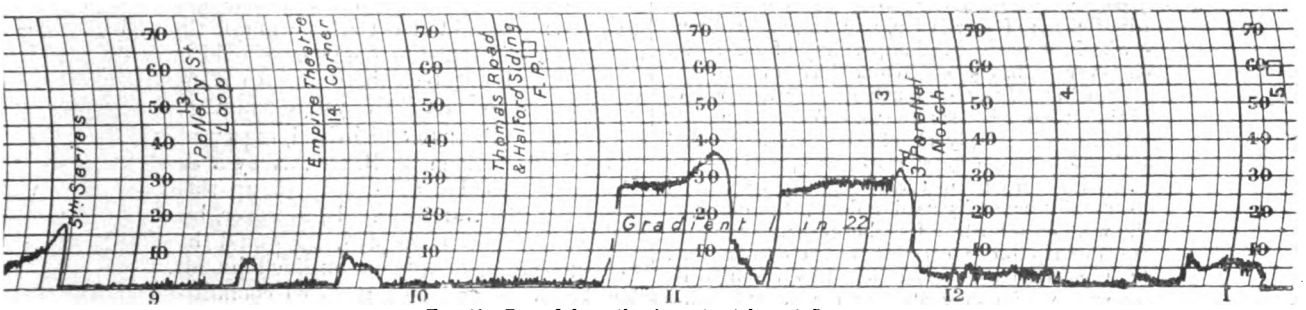

FIG. 11.—Record from the Ammeter taken at Swansea.

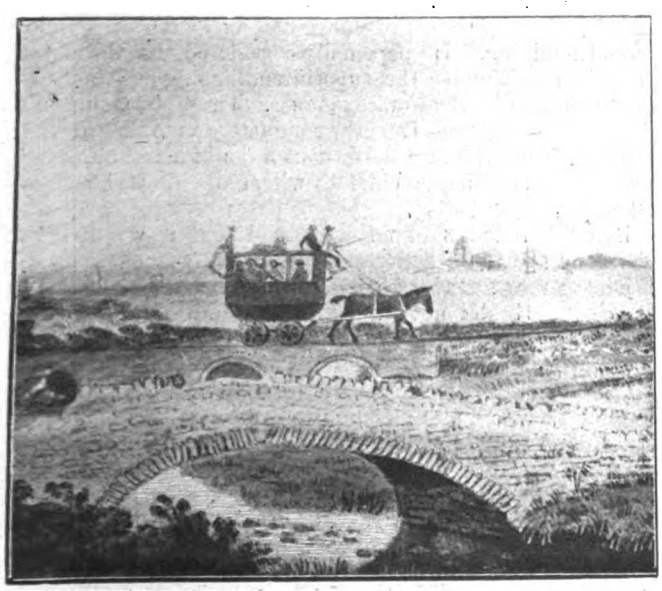

FIG. 12.—Historic View of the Mumbles Railway previous to the introduction of Steam-Engines.

Opening Ceremony.—The opening ceremony on Saturday last was commenced by the Mayor switching the current to the line at noon. A trip in the cars was then made by the guests invited over the longest section of the line, the cars returning near to the Hotel Métropole, where a luncheon was provided. After the menu had been thoroughly discussed and practically approved, Mr. GARCKE, as chairman, proposed "The Queen." The next toast was "The Town and Trade of Swansea." In the speech proposing success to the town and trade of Swansea, Mr. Garcke gave a most able exposition of the rights and wrongs of municipal trading, with local morals. He argued, quoting a socialistic society's views on the subject as his authority, that if for any reason a municipal authority decided to put tramways in the hands of a company, they should then treat that company as their agent doing a good work for them. In the license so granted all rents and remuneration should be kept low, but special provision should be made to secure the comfort of the public and a good and efficient service. A further quotation from the publication of the Fabian Society was to the effect that profits earned on the municipal tramways should be used for the reduction of general rates. This meant the taxing of the tramway riders for the benefit of the ratepayers generally. As regards Swansea itself, Mr. Garcke pointed out that they would have to carry four times the present number of passengers per annum in order to make a good dividend on the money expended in acquiring and converting the lines.

The MAYOR briefly responded to the toast. He did not agree with Mr. Garcke's remarks as to the application of profits from municipal tramways. He thought that if the profits were devoted to street improvements and general purposes, it was quite all right.

Mr. THOMAS replied for the trade of Swansea.

The next toast was "The Tramway Company," which was proposed by Mr. THORNTON ANDREWS, and replied to by Mr. D. F. SUGRUE

Reference was made to the Mumbles Railway as being the oldest in the kingdom, or the next to the oldest, as far as parliamentary powers were concerned, and through the kind offices of Mr. Sugrue and Mr. Fischer (the manager of this line) we are able to give our readers an illustration (Fig. 12) of one of the first passenger coaches on this railway. We have Mr. Garcke's authority for saying that the rails of this railway were of stone. The guests were conveyed by this railway to the Mumbles, and left to return at their own pleasure, after inspecting the pier, etc.

THE MUNICIPAL ELECTRICAL ASSOCIATION.

HUDDERSFIELD CONVENTION.

(*Continued from page 914, Vol. XXV.*)

The following paper on the combined management of tramways and lighting departments was then read by Mr. Quin:

Combined Management of Tramway and Lighting Departments.

BY R. C. QUIN, BOROUGH ELECTRICAL AND TRAMWAY ENGINEER, BLACKPOOL.

It will be admitted, by all members of the association, at least, that the municipal authority should be the lighting and tramway authority also. So far, the author begs the question,

Digitized by Google

and in dealing with it purposes to treat it solely from the municipal point of view. It does not follow that because both undertakings are owned by the municipality that it is necessarily the best policy to combine generating stations. In the majority of cases this question can readily be settled, but in some—the tramway area and lighting area, or, perhaps, the author might more correctly say their "centres of gravity"—are far from coinciding, and it may then be advisable to have separate generating stations.

Assuming, then, that in our hypothetical town separate generating stations are established for lighting and tramway purposes, is it advisable to combine the two undertakings? In order to find a satisfactory answer to this problem we must first consider whether the undertakings are, to any great extent, of a similar nature. In both cases we must have an engineer fully conversant with the problems of economical generation and distribution of electricity, and lastly, but by no means least, one who fully realises the importance of continuity of supply. Whatever tramway engineers may say to the contrary, continuity of supply is of much greater importance with electric lighting than with tramways. Who, then, best realises that continuity of supply should be the first aim? There can, I think, be but one answer to this question—the lighting engineer. I have used the term "lighting engineer" because it is the term most generally used to denote the engineer responsible for the works established for the general supply of electricity, but the description is certainly not a correct one. A general supply of electricity is not established for lighting only, but for the supply of power also, and what "lighting engineer" is not familiar with motors? What new problems does traction supply call into existence? The question of load factor certainly arises in the calculation of sizes of cables, also the various stresses in connection with overhead line and posts will have to be provided for, and the starting, uniform running, and stopping of the tramcars be ensured by suitable arrangements. But everyone of these problems is simple, and any engineer worthy of the name could readily solve them. From this it will be seen that, in the author's opinion, the man best qualified to design and work a traction system is the qualified central-station engineer. But having two stations, is it now necessary that we should have two engineers? Certainly not. In many towns multiple stations even for general supply are established, yet they are invariably under one chief engineer.

The next phase of the question to be considered is how far the engineering side of the question is dominant in a tramway supply. In the maintenance of the traction system there are several points to be considered, and I will enumerate them as follows: (1) the maintenance of generating machinery; (2) the maintenance of cables; (3) the maintenance of overhead line and posts; (4) the maintenance of track; (5) the maintenance of cars and motors: (6) the cleaning of cars; (7) the regulation of traffic; (8) the collection of fares.

The first five are entirely engineering, and without due regard to them the tramway system must cease to exist. The remaining three, though important, do not require that technical skill and training, nor the exercise of such resource, as do the former. Suppose, then, that we appoint, as chief of our tramway department, one who has previously been manager of a horse or other tramway system. How far is he fit and capable of efficiently controlling and maintaining the system? He is certainly competent to give due regard to the last three points (6 to 8); he might also have had sufficient experience to enable him to maintain the track. But his electrical knowledge would probably be extremely slight, and it would then be necessary to have an electrical engineer, who would become the servant of the tramway manager. We shall find ourselves in this dilemma, that we have placed the maintenance and responsibility for good working of the most important part of our system upon a servant, and placed over him a man incapable, by reason of his want of knowledge, of properly controlling him. The engineering side is without doubt the most important in a mechanical, and especially electrical, system of traction.

But it may be said that the collection of fares and regulation of traffic requires experience which the electrical engineer may not have. Granted that it may be so, it does not necessarily follow that the engineer would control this. These duties could be placed upon a traffic manager. As to whether this traffic manager would be the servant of the engineer is largely a matter of the personality of the two men; and to the author there appears no difficulty whatever—and he speaks from experience—in thus separating a tramway system, though there are advantages obtainable by placing the whole system under one responsible head. The question of collecting fares has some analogy to the collection of electricity or gas rents. In most towns, the author believes, this is not done by the electrical engineer, but by a separate department of the municipality.

What the author would most wish to impress upon his readers is the fact that the design and working of an electric traction system is almost entirely an engineering problem, and that the man best qualified to carry out this work is the competent central-station engineer.

Mr. J. F. C SNELL, of Sunderland, said that the author's paper raised a most important question. In Sunderland they had solved this question by making one engineer responsible for both departments instead of having two independent engineers, and this engineer (the speaker) was also general manager of the tramways. It was deemed that the engineering side of the management preponderated. When the trams are started the following subordinates to the engineer will be appointed: an assistant engineer, who will have charge of the car sheds, of repairing the roads, and of maintaining the cars; a traffic manager, who will have complete charge of the staffs on the cars, and who will look after the running of the same to schedule times. The financial department will also come under this manager's care. He thought that the solution of the difficulty was a good one, and that the engineer should have the complete control, and not be subordinate to a non-technical man. They hoped to start their system running next month.

Alderman PEARSON, of Bristol, regretted that the problem did not affect them at Bristol, as by a small majority the Corporation had decided to give up their opportunity of acquiring the tramways. If, however, his proposal in this respect had been adopted, he would have arranged the management generally as outlined by Mr. Quin. He did not think it well to have two committees on the same corporation both concerned with works for generating electricity. He believed in getting the tramway and lighting load supplied from the one station. He quite agreed with Mr. Snell's division of the labour and responsibilities of the tramway department.

Mr. PHILIP DAWSON agreed, from a contractor's point of view, with the author's proposals, as he found in his capacity that the more authorities one had to deal with the more difficult it was to get any single point decided. With two committees to please, and a tramway engineer, the contractor was continually having to stop work for some reason or another. Without a doubt the man most qualified to design an undertaking should also have the working of the same, and for this purpose an engineer was required.

Mr. S. E. FEDDEN, of Sheffield, said it was of vital importance to the tramway undertaking that only one flag should be flying. He personally considered that the motormen should be under the superintending engineer, and the conductors under the traffic manager. The motormen would then take instructions from the conductors as to the stopping and starting of the cars. Without a doubt a technical man should be the ultimate chief to whom all things should be referred.

Bailie WILLOCKS, of Glasgow, said that it was a great pity they had not a congress of tramway managers in an adjoining room, so that their views on the question might be heard. He did not suppose they would agree with the author of the paper. With regard to the situation in Glasgow, it was rather a question of whether Jonah would not swallow the whale instead of the whale swallowing Jonah. They had an exceedingly strong tramway manager, Mr. John Young, and while their electrical engineer was at the time an exceedingly capable man, he had not the personal influence and character to get charge of the two undertakings. Still, they had managed to keep their electric light undertaking in their own hands. They were doing good work in this, and found their present engineer, Mr. Chamen, a very good spender of money. As regards their tramways, which they hoped to have completed for the exhibition next year, the tramway equipments were in the hands of Mr. Parshall. There was no doubt that to make a good tramway manager a strong personality was wanted.

Alderman BRUCE, of Sunderland, said it was absurd to have two committees and two electric power stations in one town, both belonging to the same corporation. He thought that the electrical engineer who laid down the plant should have full charge in working the same.

Alderman WOODHEAD, of Halifax, said that by having one combined station for traction and lighting, there would be a great saving in staff and working expenses. He agreed with the author as to the division of labour in connection with the undertaking after it was started, but they ought not to expect the electrical engineer to take over the detailed duties of a traffic manager. In Halifax they had

Digitized by Google

two committees, and the Tramway Committee bought its current from the Lighting Committee. The Electric Lighting Committee last year made a net profit of £5,400 from the following scale of charges: 4d. per unit for lighting, with discounts; 2½d. per unit for current used on motors; 1½d. per unit for current sold to Tramway Committee.

Mr. H. C. BISHOP, of Wigan, also agreed in the advisability of having one committee to maintain both tramways and lighting. In Wigan they started with a clear field—*i.e.*, no tramways or lighting—and hence were able to choose a system of supply which was suitable to both purposes.

Mr. C. S. VESEY BROWN, of Lincoln, advocated having one committee split up into three or four sub-committees: one of these to look into generating plant, one for the distributing plant and mains, one would have charge of the financial arrangement and returns, while the fourth committee would have charge of the tramways. With very large stations he was not quite certain that when the size exceeded 30,000 h.p. there was any further advantage in adding plant in one station instead of building two; 30,000 h.p. was larger than any engine contained in one steamship.

Mr. QUIN, in reply, said that so little contentious matter had been raised that he agreed practically with all that had been said.

The discussion then closed with a vote of thanks to the author.

The last paper for discussion on Thursday was the following:

The Reduction of Light-Load Losses in Alternating Supply Works

BY HORACE BOOT, CONSULTING AND RESIDENT ENGINEER TO THE TUNBRIDGE WELLS CORPORATION.

The question of light-load losses in electricity works, be they continuous or alternating, deserves more attention from engineers than it has hitherto received. These losses might be divided under two heads—viz.:

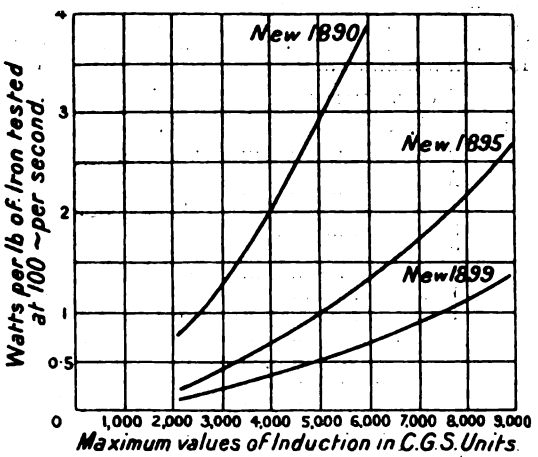
Works Losses.—(1) Fuel used in keeping up steam ready to supply; (2) radiation losses in boilers, separators, brickwork, steam and drain pipes; (3) in running larger generators at light loads to enable the voltage to be kept constant, should motors or other apparatus requiring heavy starting currents be in circuit; (4) wages paid to the men during the hours of light load; (5) interest and sinking fund on the buildings and machinery during light-load hours.

Distribution Losses.—(1) Losses in transformers (magnetising watts); (2) losses in the shunts of meters; (3) interest and sinking fund on capital, outlay on cables, and distribution appliances. (Nos. 2 and 3 apply equally to alternating and continuous systems, but No. 1 only applies to the alternating, except where continuous-current transformer systems are in use.)

The author does not purpose in this short paper dealing with the losses under the works heading, as there are many ways in which these can be reduced to a minimum, but he has not yet come across a system, be it direct or alternating, in which these in the course of a year do not total up to a very large amount, which would make an appreciable difference in the cost of supply if they could be overcome. In distribution, the most important losses requiring consideration, and which are more or less complicated, are the transformer losses during light loads, and since it is increasingly evident that in the near future transformers dealing with alternating currents of mono-, di-, or polyphase will be used by both what are known as "continuous current" and "alternating" engineers, it is important to both sections to endeavour to meet these losses, and to ascertain the manner in which they can be best reduced to a minimum. Low-tension engineers of a few years ago are all of them propounding schemes involving high pressures, and it is notable that all these schemes propose using alternating currents and transformers, or motor-generators. There is a consensus of expert opinion that the most economical way to supply electricity over large areas, and on a large scale, is by a form of high-tension transmission, and therefore the author does not feel called up to apologise to his continuous-current friends for wasting their time over problems which they now see they will have to tackle in the future.

The transformer losses may be divided into "iron" losses and "copper" losses; the iron losses being dependent upon the eddy-current loss, varying, of course, with the temperature and periodicity, and the contact between the adjacent plates and hysteresis loss depending upon the quality of the iron and the temperature to which it is heated, the E.M.F. curve, and the maximum induction; also, a not unimportant item, the mechanical strains and stresses to which it is exposed. The copper losses may be summed up as the $C^2 R$ loss due to the magnetising current and resistance of primary winding. These, of course, again vary as the square of the current, the resistance of the copper, the temperature to which the winding attains, sectional area of same, and the length. The author has found, however, that the $C^2 R$ loss due to magnetising current is about ·20 per cent. of the maximum output. It is important to note that the limit of work which a transformer can undertake is governed by the overheating permissible, as this exercises a very important function when short-circuits on the distributing networks take place, as the transformer only requires to be fused to its burning-up limit, which is usually very much higher than its output. It will be seen that it is important to design a transformer in such a manner that it has sufficient means of radiating its heat, as only in that manner can a transformer be kept within decent limits in weight and size.

With regard to improvements in transformers, it is interesting to reproduce a curve having for ordinates the watts per pound of iron tested at 100 frequency, and for abscissæ the maximum volts of induction in C.G.S. units, for which the author is indebted to Mr. Berry. From this it will be seen that the efficiency of transformers has advanced enormously since 1890.



CURVE A.—Showing Advance in Transformer Efficiency.

This increase of efficiency plays a very important part in the light-load losses, as by comparing efficiency curves it is now possible to obtain an all-round efficiency, including light-load hours, of something like 94 per cent.—that is, taking 20 hours at no load, two hours at full load. Many works, however, are fortunate in obtaining a longer period of load. Comparing the efficiencies for the last 10 years, there has been an improvement of something like 16 per cent. It therefore will be seen that one of the ways to reduce light-load losses is to instal transformers of high quality. It is, of course, apparent to anyone that the copper losses from the all-day efficiency point of view are of less importance than the iron ones, because the iron, like the poor, "is always with us," whereas the copper losses do not play such an important part until the transformer becomes loaded. The ageing of the iron is a very important matter, and the author has found from tests carried out that in the case of old transformers the effect of age has been to increase the magnetising watts by as much as 45 per cent. This should not be the case with our present knowledge, as in the case referred to it was due to the number of lines forced through the iron to a very large extent, whereas if the iron density had not been pushed so far, also the temperature limit, both in the iron and in the copper, there is no reason why the watts taken to magnetise should have increased so enormously. In other instances tried by the author, they have increased 10 per cent. after nine months' use. He thinks it is here that in all probability our systems put down with English plant will eventually show their superiority over American-made machinery, as it is well known that Americans load their machinery up to the limit. In his transformer specifications the author finds it necessary to insert a clause, that the tests on the core losses shall be taken after the transformer has been six months at work on its full load, and he is even of the opinion that this six months would be better if it were 12 months, because a transformer appears to get better as its gets older, until it reaches a certain point, and then the increase in iron loss runs up. The ageing which increases the iron loss can be governed by temperature rise, the quality of the iron, and the strains of a mechanical nature to which it is exposed when in use. In a table below are given the actual tests obtained from different sizes of transformers in sub-stations in Tunbridge Wells, showing the increase in magnetising watts with age, also the number of watts used on large transformers (calculated) during the period of light load. This is important, as from these figures can be calculated the saving that can be effected by switching the transformers in or out, according to the conditions of load, making, of course, provision for the labour, interest, and sinking fund required for doing this.

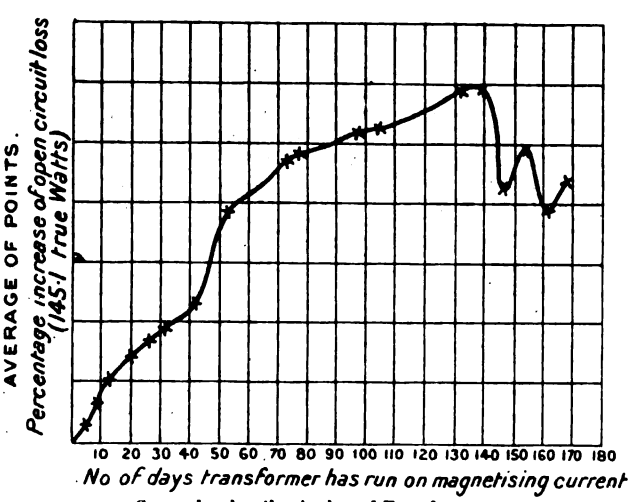
With regard to ageing of transformers, there is an interesting curve published by the London Electric Supply Corporation in 1895, and which, with their kind permission, is reproduced here.



Curve showing the Ageing of Transformers.

The author has calculated that at Tunbridge Wells the units generated during the period of no load in 1899 amounted to 32,920. The units supplied to the transformers in circuit, calculated taking the same number of hours, equals 10·75 × 3,000 hours = 32,250, and the total number of units generated in 1899 equals 466,901, showing that the number of units due to core loss amounts to 6 09 per cent. of the whole. The cost of supplying these "core loss" units (1·5d. per unit) amounts to £201. 11s. 3d., and it is this figure which the author is hoping at some future time to save entirely, and then he will be in the same position as his "continuous-current friends," so far as efficiency of distribution goes. By adopting the network interconnection system and running a sufficiently large low-tension main into the works, or, if the works are situated some distance from the distributing area, supplying the whole of the distributing networks from either the works or one sub-station, the whole of the loss, with the exception of that occasioned by the use of one transformer, can be saved, against which, however, must be balanced the labour involved in visiting these sub-stations twice a day for the purpose of switching on and off the primary and secondary. The switch gear in these sub-stations should be as simple as possible, so that it does not require a particularly skilled man to operate same, nor should it be possible for him to kill himself.

A few years back Mr. Walton (then chief engineer to the Metropolitan Electric Supply Company) brought out and patented an automatic transformer switch, to switch in the transformers on both the primary and secondary as soon as the load became sufficiently heavy to require a supply from that transformer. These have been in use since March, 1897, at the sub-stations in Marylebone-passage, Brook-mews, Rathbone-place, and I believe the London Electric Supply Corporation and the Brush Provincial Company are also using them. This automatic switch is most useful in towns subjected to sudden demand, as the engineer can rest assured that a sufficient number of transformers will be switched in to cope with the load, and will not have to depend upon the vagaries of human intelligence. It is, of course, easy for any station engineer to calculate the saving effected in switching off these transformers, which becomes more marked in towns with a poor load factor, and in the provinces, where sudden heavy demands are almost unknown, from the following formula :

$$\frac{\left\{\begin{matrix}\text{the number of hours}\\ \text{per annum the trans-}\\ \text{former is not loaded}\end{matrix}\right\} \times \left\{\begin{matrix}\text{the cost per Board}\\ \text{of Trade unit to}\\ \text{generate}\end{matrix}\right\} \times \left\{\begin{matrix}\text{core loss}\\ \text{in units}\end{matrix}\right\}}{1{,}000}$$

Another advantage to be obtained by being able to cut out all transformers during the hours of light load is that it places all the feeders, with the exception of one perhaps, at the disposal of the mains superintendent for testing purposes, or working thereon, and then there can be no excuse for not keeping them in perfect condition, as they can be tested daily.

The question of the best position for fuses in the high-tension feeders is a very troublesome one, and the author has found that the safest place to have fuses is at the works, and at the works only, especially when we get to the condition of things where transformers never go wrong ; as, unless fuses are constantly watched in the sub-stations and frequently changed, no reliance whatever can be placed upon them. I venture to think, in the analysis of the number of extinctions and the cause, 75 per cent. could be put down to the erratic behaviour of fuses, both on the high-tension and the low-tension side, and for that reason fuses should only be inserted where it is dangerous to do without them. In the distributing networks I have not found it necessary to insert fuses, except at the point of interconnection as above stated. This method of reducing the light-load losses to the minimum, unless precautions are taken, may introduce serious results, and be the cause of cables and transformers breaking down.

Some time ago there was an article in the *Electrical Review*, by Mr. Hay, proving that when breaking a current, at the instant of breaking the current it had a higher value than its normal maximum, the core being left more strongly magnetised than when under working conditions. In some experiments carried out with transformers it has been proved that transformers do not, as a rule, break down at the instant of connection, but the core settles down to the ordinary cycles of magnetism gradually, and there is no rise in potential difference across the terminals ; but if they break down the damage was done when switching off. It would be interesting to hear from other members if they have found the life of the cables and the transformers, when intermittently used, to be shorter than when they are in constant use. Beyond the strain of switching on and off, the author does not see that there should be any difference, unless the transformers get unduly heated, in which case the continual heating and cooling may do mechanical damage.

There is another danger which may be introduced at the time of switching in and out—viz., the capacity effect—but, provided care be taken to switch in the outer conductor first, and switch out the inner conductor first, it is unlikely that the conditions will be such as to break down the cable. Experiments were performed by Prof. Fleming and Mr. Alexander Siemens on the Deptford mains, which will be within the memory of the members, and the able articles written at the time with respect to the same are worth studying. One of the points to be borne in mind, however, is to avoid any discontinuity in the outer conductor of a concentric cable, and this can best be secured by earthing the outer without any fuse

Digitized by Google

in circuit. In the *Review*, in March, this subject was ably treated by Mr. Gisbert Kapp, the article being the translation from the *Elektrotechnische Zeitschrift*, Dec. 28, 1899, in which he depicts some conditions into which we unhappy alternate-current engineers may get and break down our cables. However, it is rarely that these conditions are present, but it is always advisable to take precautions such as the adoption of Neufeld's rule for switching in and out: "The earthing of the outer conductor, and omission of all fuses in the outer."

It is important that transformers should be constructed to withstand a considerable load for a short period, as when such is the case it is possible to use a transformer that will be fairly well loaded at normal times of heavy demand, and occasionally withstand a great deal more. In some of the transformers the author has tested there appears to be very little limit to their overloading capacity—one in particular, a 5-kw. transformer, easily withstood a load of 12 kw. without burning up; but he finds that when the larger sizes are dealt with, the manufacturers are not so generous in giving more than you pay for. From calculations and tests made, it appears that about 140 watts are wasted in core losses for every thousand watts supplied to the lamps. Considerable economy may be gained in distribution by keeping the number of sub-stations to a minimum—in fact, the Board of Trade alteration in the permissible pressure of supply has been an immense boon to alternate-current as well as to continuous-current engineers. The insulation of the distributing mains is better maintained in the case of alternating than appears to be the case in continuous-current distribution systems, in which, by increasing the pressure, "shorts" and other troubles have been experienced.

Taking the cost of coal, which in Tunbridge Wells is very heavy, at 1d. per unit, the cost of energising the transformers on circuit amounted to £137. 3s. 4d. in 1899. In order to overcome this loss it is necessary that the low-tension networks supplied from the various sub-stations be interconnected, as it is then possible to switch off all the transformers, except one, on both primary and secondary. For this purpose the author has arranged the networks so that they can be fed in the daytime from a transformer situated at the works, and the whole of the transformers in the sub-station can be switched out of circuit. This at once reduces the light-load losses from 10,750 watts to 590, against which, however, has to be put the cost of the extra switch gear and men's wages, unless an automatic switch is used; but it will be seen that this arrangement enables the feeders to be tested every day, worked upon, and kept in perfect order, without in any way discontinuing the supply, which, as prescribed in the Act, is continuous during the 24 hours. In towns where it is possible and economical to build a large sub-station and make it a centre of distribution, transformers can be banked, and it is usually arranged for one man to attend to these, but in Tunbridge Wells the area is very extensive, and no particular sub-station can be looked upon as the feeding centre, so that the most economical way is to place one large transformer in each instead of providing several small ones, and switching them in as the load comes on. The author has found, from experience, that the most satisfactory arrangement for fuses on the outer networks is to make them comply with the following conditions: Each transformer sub-station should be allotted a certain small area, which should not exceed the maximum load of the transformer at the time of full demand, even if it were isolated from the other sub-stations. A fuse box on the distributors should be inserted before connecting that particular transformer area with the other network area. This is what he has carried out throughout, and found to work admirably. It is advisable to test the transformers at least once a year, to obtain the magnetising watts on open circuit, and the full load voltage drop, and compare them with the previous tests, and in most instances it will be found advisable to scrap the old transformers, and buy others more up to date, having more permanent efficiencies. With a reduction of frequency to a standard of 50 periods, many alternating troubles would disappear, such as impedance. With regard to skin effects, Lord Kelvin showed that the current only penetrated to ·0393 of an inch after increasing the frequency above 150, but the loss occasioned by this may be more or less neglected with low periodicities.

A very important point to bear in mind in alternate-current distribution is to keep the power factor as near unity as possible. This problem is not easy, and is often the cause of great loss in efficiency. The effective volts and amperes rarely exceed ·75 of those apparent; it may be much less than this when motors, arc lamps, and various inductive apparatus are in circuit. This wattless circuit loads up the armatures and the cables, producing considerable phase difference. However, provided the frequency is kept low, the difficulties can be overcome, as the current lagging in phase depends upon the inductance in circuit and the periodicity. Various suggestions have been made for introducing capacity in order to give lead, and thus nullify the lag in an alternate-current circuit caused by induction, but the author is not aware of any system being in operation in this country. When it is necessary to calculate actual resistance these effects present difficulties, as it is apparent that the resistance must change according to the kind of load.

Another source of waste, although of not very large moment, is the energising watts supplied to maintain the shunts of the meters when no energy is being consumed. It will be seen that

APPENDIX.—Information Obtained from 17 Towns.

Town.	Do you interconnect networks with fuses?	Do you bank your transformers?	Are any arrangements made for reducing the idle magnetising watts in time of light load?	Magnetising watts and amperes given to mains.	Do you use any automatic switch for cutting-out transformers?	Magnetising watts more after using transformers some time, percentage?	Does your low-tension network come into the works?
Bath	No.	Yes.	No.	—	No.	—	One circuit
Bedford	Only occasionally.	In some cases	No.	5 kw. and 6 amps.	No.	—	No.
Bolton	No.	No.	—	—	—	—	Yes.
Bristol	Yes.	Yes.	Nothing daily.	About 30,000.	Not now.	—	One does.
Cardiff	Yes.	Yes.	In the summer.	—	No.	—	No.
Croydon	Not generally.	Yes.	Yes.	About 10 kw.	All switching off is done by hand.	No increase noticed hitherto.	No.
Derby	No.	Wherever possible.	In the summer.	7 primary amperes full load current at present about 300 amps. Mag. watts estimated about 10 kw.	No.	—	One of four
Hanley	Yes.	Yes.	No.	7 amps. at 2,050 volts.	—	—	No.
Halifax	No.	As little as possible.	No.	About 16 amps. at least at 2,000 volts.	No.	Cannot say definitely.	No.
Harrogate	Yes.	Yes.	No.	About 13 apparent amps.	No.	—	No.
Huddersfield	No.	Yes.	No.	About 15 kw.	No.	Depends very much upon make of transformer.	No.
Kingston-upon Thames	Yes.	Yes.	Can be switched out in sub-stations.	7 amps. at 2,100 volts.	No.	Yes.	Not at present.
Newport	No.	Yes, in sub-stations.	No.	20 kw.—15 amps.	No.	—	No.
Portsmouth	Occasionally	No.	No.	Average 15 watts per kilo of rated output of transformers.	No.	Not ascertained.	No.
Southport	Will do so this year.	Yes.	No.	Mag. power amounts to 16 kw. and the current 8 9 amps.	No.	Not appreciable.	No.
Wolverhampton	Yes.	—	—	—	—	—	No.
Worcester	No.	Yes.	No.	8 amps. at 2,000 volts.	No.	Have never determined.	No.

Digitized by Google

there are 1,000 meters on circuit, all of them taking a small amount, and most of them taking that amount for 20 hours out of the 24 for no purpose, that a saving would be effected if this shunt were cut out when no current was flowing through the series coil. The author has introduced into Tunbridge Wells a small relay, which is governed by the current in the series coil, and is made to close the shunt circuit of the meter immediately ·1 of an ampere flows through it. The arrangement is simple and works admirably, the three points in its favour being: (1) it prevents consumers complaining of the noises their meters are making all day long when there are no lights burning; (2) it prevents consumers thinking that the meter is registering when they are not using any energy; (3) it saves the wasted watts during the time when the meter is not registering.

In conclusion, in order to reduce the light-load losses—(1) the low-tension distributing network must be interconnected, each sub-station interconnection being by a fuse on both poles; (2) the supply can be given by one transformer, preferably situated at the works, and so arranged as to feed the whole networks; (3) in each sub-station switch gear must be arranged to disconnect the primary from the source or sources of supply, and the secondary winding from feeding or being fed by the low-tension network; (4) unless automatic switches are used, it is the mains superintendent's duty to arrange with certain men on their way to work to open the switches and switch in the transformers at sunset; (5) the feeders should be so arranged that during the hours of daylight they can be tested and all pressure removed. In some instances, of course, this would necessitate cutting off the supply to a few isolated houses which may have separate transformers, but no doubt this could be arranged in the price charged to these consumers, as they would be situated outside the "compulsory" area.

Mr. L. ANDREWS, of Hastings, opening the discussion, remarked that he had a paper on somewhat the same subject coming on the next day. He thought that every engineer should calculate the results of switching off his transformers. He had not found any great advantage at Hastings. For instance, on one feeder using 2,000 volts the condenser current was 0·9 of an ampere. When two 18-kw. transformers were switched on to the end of this feeder the current actually fell to 0·85 ampere. At times of light load current was quite as important as energy, as on the current depended the size of the plant which had to be kept running. He did not agree with the author as to the use of fuses in transformers, which he thought should only be put in so as to protect the feeders if a transformer burnt out.

Mr. H. FARADAY PROCTOR, of Bristol, referred to that part of the paper in which the noise of meters is complained of. He thought there was no difficulty in selecting meters which do not make a noise, and also that the watts consumed in the shunts of the meters were so small that it was not worth while switching them off. Taking the whole year through, these watts only worked out to 18 units per meter, which at 1d. per unit would hardly repay for the automatic gear and the risk of failure. As regards the switching off of transformers in the sub-stations, here again he considered that the cost of switching off by hand labour did not bring any commensurate advantage. At 1d. per unit, 4d. per hour would pay for all the energising current for the transformers referred to in the author's paper, and he did not think it worth while to send a man round to the sub-stations in order to save eight hours' supply at this rate. As regards the switching on and off of feeders, he found that there was no trouble from a rise of voltage if one always switched on the low pressure before the high, and reversed the sequence of events when switching off.

Mr. H. S. RUSSELL agreed with the author that it paid to scrap old transformers if their core losses were high. As regards the increase of these core losses, with time it would be seen that it was not such a simple phenomenon as was hoped, as there were irregularities in the curves which could not be predicted.

Mr. PRUSSMAN, of Doncaster, raised the question as to whether the relays for the switching in and out of the meters could be relied on to work at the current mentioned—0·1 ampere. If the relay did not switch on when 0·15 ampere was going through, it would mean that an 8-c.p. lamp could be burnt continuously without registration, as the meter would be out of circuit.

Mr. J. F. C. SNELL, of Sunderland, raised some questions as to the figures in the paper, which he thought were rather too favourable to the alternating-current system of supply.

Mr. EDGCOME, of Kingston, said he had also had complaints of the noise made by meters on the alternating-current system.

Mr. W. B. ESSON asked the author if he could give the length of time that each of the transformers referred to in the paper had been in use, in order that one could see how long it took for the core losses to increase to the extent shown. He pointed out that if the whole of these losses were saved, it would only amount to £150 per annum, and it was a question as to how much one could spend, and how much complication it was worth while to introduce in order to save a certain proportion of this amount.

Mr. H. L. P. BOOT, in reply, explained that the figures to which Mr. Snell referred were for the core losses only. He would try to give the information which Mr. Esson asked for in the *Journal*. He explained that the noise in the streets in Bristol was very likely sufficient to prevent the noise from the meters being heard. Tunbridge Wells was a health resort, and the noise of the meters was objectionable to invalids. Mr. Boot caused much amusement by explaining that the meters and the visitors were both placed in the cellars.

The meeting adjourned at 1 p.m., which gave the members time for lunch before attending the Mayor's garden party, which was held in the Beaumont Park from 3 to 6 p.m. This park, which is a great credit to the town of Huddersfield, was originally a quarry, and the irregularities in the ground caused by the quarrying operations have given every facility for making the ornamental park which is now enjoyed so much by the inhabitants of Huddersfield. Two bands were engaged for the occasion, one of which played in the band pavilion and the other in the terrace opposite the castle. From this park a most extensive view of the country round Huddersfield can be obtained, and the rising smoke from Huddersfield was also exceedingly apparent at the time of the garden party. It is wonderful, however, that the country should keep so exceedingly fresh within such a short distance of a large manufacturing town.

The annual dinner of the Municipal Electrical Association was held in the town hall at night, when Mr. Mountain, the president, again took the chair. The toast list included the following: "The Queen and Members of the Royal Family," "The Corporation of Huddersfield and the Electricity Committee," proposed by Alderman Bruce, M.P., and replied to by the Mayor of Huddersfield; "The Guests," proposed by Alderman G. Pearson and replied to at length by Sir Thomas T. Woodhouse. The toast of the evening, "The Municipal Electrical Association," was placed in the hands of Councillor G. Thompson, and was, of course, replied to by the President.

Mr. W. A. CHAMEN, in proposing "The Electrical Industry," gave some interesting reminiscences of the pioneer work in electric lighting. He referred, for instance, to the arc lighting carried out in those days when one dynamo was provided for each light, and when the sparking at the commutator was the recognised method of telling if the lamp had lighted up. In the case in point this test failed because the commutator had distributed itself about the engine-room.

The toast was replied to by Mr. S. Z. DE FERRANTI, who made some interesting points on the developments of electrical industry, and the way it was hindered and helped by municipal corporations.

Mr. MACLAREN also replied.

The proceedings closed with the toast of "The Press," proposed by Mr. EDGCOME.

The Johnson-Lundell Company.—We understand that this company is now getting in working order, having appointed Mr. A. Tilley as secretary, and Mr. A. F. Hall as engineer, the latter of whom has had extensive experience in the States under Mr. Parshall. The financial state of the company leaves nothing to be desired, and we wish Mr. Hall every success in working its manufacturing business.

LOCAL LOANS.

A glance at the annual reports of the Local Government Board, although these reports are somewhat belated, gives some interesting information. Just at the present juncture we may refer to the 1898-9 report, that for 1899-1900 not being yet available. Herewith we give certain figures which may be of use for reference in discussing municipal matters. These show the receipts and expenditure, also the loan on capital accounts in certain more or less debatable directions. The figures are instructive reading, and when those of the forthcoming report are issued and added will prove a little startling. We now simply give the figures, reserving comment.

TABLE I.—EXPENDITURE (not out of loans) AND RECEIPTS FROM OPERATIONS CONNECTED WITH WATER, GAS, AND ELECTRICITY.

Items.	1892-3.	1893 4.	1894-5.	1895 6.	1896-7.	1897-8.
Expenditure on waterworks	£1,010,008	£1,093,622	£1,112,589	£1,218 484	£1,192,130	—
Revenue from waterworks	2,723,303	2,825,652	2,875,984	3,039,413	3,166,824	—
Expenditure on gasworks	£3,480,925	£3,698,514	£3,566,318	£3,624,533	£3,753,205	—
Revenue from gasworks	4,333,589	4,510,784	4,750,738	4,718,528	4,864,381	—
Expenditure on electric lighting	£2,237	£24,464	£33,605	£44,554	£61,149	—
Expenditure on electric lighting and supply (other than public lighting)	18,740	37,514	92,540	126,988	177,842	—
Revenue from electric lighting and supply	21,081	44,123	123,580	195,472	329,819	—
Expenditure on tramways	£51,818	£61,063	£109,981	£134,737	£160,736	—

TABLE II.—LOANS TO LOCAL AUTHORITIES.

	1892-3.	1893-4.	1894-5.	1895-6.	1896-7.	1897-8.
Gasworks	£401,985	£727,550	£749,964	£399,879	£539,396	—
Electric lighting and supply	115,248	572,645	559,299	596,549	1,186,739	—
Public lighting not included under other headings	1,996	2,857	4,464	1,383	9,109	—
Tramways	58,996	186,645	173,458	66,859	12,684	—

TABLE III.—EXPENDITURE OUT OF LOANS.

	1892-3.	1893 4.	1894 5.	1895 6.	1896-7.	1897-8.
Gasworks	£547,473	£796,826	£598,360	£455,839	£641,515	—
Electric lighting and supply	165,465	445,645	704,278	590,423	1,087,231	—
Public lighting not included under other headings	2,398	5,732	1,546	11,561	9,780	—
Tramways	57,427	211,190	54,263	172,680	144,074	—

TABLE IV.—OUTSTANDING LOANS.

	1892-3.	1893 4.	1894 5.	1895 6.	1896-7.	1897 8.
Gasworks	£15,533,605	£16,128,586	£16 931,943	£17,162,143	£17,433 760	—

Tramways	1,295,702	1,433,744	1,466,610	1,604,412	1,585,295	—

LIGHT RAILWAYS.

The Light Railway Commissioners have submitted to the Board of Trade an order for the construction of light railways in the county of Worcester between Bromsgrove railway station, Bromsgrove Town, and Lickey End.

At a recent meeting of the Bowness District Council the proposed electric tramway to connect Bowness, Windermere, and Ambleside was discussed, and the Council resolved to continue their opposition to the scheme.

The Cinque Ports Light Railway, Limited, is the title of a company which has been formed, with a capital of £25,000 in £1 shares, to take over and continue the application under the Light Railways Act for a provisional order for the construction of the Cinque Ports light railway, and to carry on the business of railway and general engineers, railway and tramway proprietors, etc.

The complete scheme for the Mansfield and district light railway has now received official approval, and the substance of the two applications will be drafted in one order The extensions to Pleasley-hill and the cemetery at Mansfield, and from Sutton to Hucknall Huthwaite are estimated to cost £36,487.

The President of the Board of Trade in a return in regard to the operation of the Light Railways Act, 1896, states that no loans have yet been approved under Section 4 of the Act. The following are the free grants which have been approved conditionally by the Treasury under Section 5: (1) The Mound, Embo, and Dornoch, company incorporated by the order, £14,000; (2) Forsurard, Melvich, and Port Skerra, company incorporated by the order, £20,000; (3) Fraserburg and St. Combo, Great North of Scotland Railway Company, £5,000; (4) Kelvedon, Tiptree, and Tollesbury, Great Eastern Railway Company, £16,000; (5) Elsenham, Thaxted, and Bardfield, company proposed to be incorporated by the order, £16,000; (6) Tanat Valley, company incorporated by the order, £18,000; (7) Leek, Caldon Low, and Hartington, company incorporated by the order, £10,000; (8) Welshpool and Llanfair, company incorporated by the order, £7,000; (9) Wick and Lybster, company incorporated by the order, £20,000. Order authorising the light railway not yet confirmed for Nos. 4 and 5.

The Staines and Egham Light Railway Company, Limited, intend to apply for an order authorising the construction and working of light railways in the Egham district.

Sir Courtenay Boyle held an enquiry on the 28th ult. into the Barnsley and district light railway order. The promoters—the British Electric Traction Company—were represented by Mr. Sydney Morse. The objectors were the Barnsley Corporation, represented by Mr. Soutter (Durnford and Co.), and the Worsborough Urban Council, for whom Mr. Oddie (Torr and Co.) appeared. Mr. Soutter said the Corporation of Barnsley objected to Sub-Clause 1 of Clause 6 as to the supply of electrical energy. It proposed certain conditions for the supply of electricity by the Corporation to the company, but the Corporation had the power already, and they considered this sub-clause unnecessary. They did not know how it got into the order at all. This and various other clauses objected to were passed, and Sir C. Boyle said, with regard to the company selling the undertaking, that it was not conceivable that the Board of Trade would assent to the sale to a company or person without consulting the local authority. They had set their face against transfers and concessions.

It has been decided to commence forthwith the construction of a light railway from Ludgershall, over the War Office property, to Tidworth and Clarendon Hill, the site for the barracks on Salisbury Plain.

At a recent meeting of the Parish Council of Llannor, near Pwllheli, Mr. Evan R. Davies, Pwllheli, and Mr. Bennett, Manchester, explained the proposed scheme for a railway to be worked by electricity between Nevin and Pwllheli. The following resolution was passed: "That we approve and give our support to the construction of the railway, as we are convinced that it would benefit the various districts interested, both commercially and agriculturally, but that we record our opinion as to the following points (1) that the gauge ought to be the ordinary one of 4ft. 8½in.; (2) that it would be desirable for the rails to be laid from Pwllheli as far at least as Efail Newydd, outside the public road; (3) that the road for the distance mentioned should be widened to 30ft.; (4) that the Council should have the right hereafter, if necessary, to have the railway fenced, and that Mr. J. Evans and Captain John Roberts be appointed to appear before the Light Railway Commissioners' enquiry at Pwllheli."

The Board of Trade have confirmed an order for the construc- of a light railway, promoted by the Railway Developments, Limited, from Highbridge to Cheddar.

A conference is to be held in a fortnight, with regard to the Driffield-Hornsea light railway proposal, between the promoters and the Hornsea Council.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

OLLA PODRIDA.

After the rejection of the Dublin Electric Bill on the third reading on Monday, the House of Commons could hardly stultify itself, hence the St. Marylebone Bill was rejected on the second reading on Tuesday last. The hearty sympathies of the profession must be given to the promoters of these Bills, and to Mr. Campbell Swinton, who has had to see his Tyneside Bill consigned to the limbo of the "not passed." It is perfectly evident that the House has not condemned the St. Marylebone Bill upon its merits. It had little in common with the Dublin Bill. In the latter case the authority is actually in being as an undertaker, and is moving in the matter of extension; in the former—that is, the St. Marylebone case—the authority which it is promised shall act is not yet in existence, and will probably have so many things to consider in the early years of its life that actual work will not be commenced for two or three years more. As a matter of fact, both these Bills have been thrown out by lobbying tactics. In each case strong efforts have been made, not to discuss upon merits, but to throw them out in any case. Events are moving quickly, and while the House acts in favour of municipalities, the committee on the Power Bills is taking a far more sensible course and trying to put the matter upon a satisfactory footing. Coleridge said, "In politics, what begins with fear usually ends in folly," and this is borne out by the past twenty years of legislation. Any fool's scheme can be passed through Parliament provided that it is heralded by enough sounding brass and seconded by "votes." Leaders fear the latter, and notoriety seekers provide the former. We have been amongst the most fervent advocates of municipalisation, but only to a certain point; we have never advocated the giving of powers to authorities by means of which they shall be able to put back or to stay the hand of time for years, if not for ever. The Board of Trade is not of much account. It is a species of red-tape hydra—once getting an idea, sticks to it till long after the work carried out on the lines conservant with that idea is obsolete. A local authority has infinite trouble in getting a provisional order when a company occupies the ground unless it buys out the company, and *vice versâ*, but usually buying out means the purchase of obsolete plant and a costly fight as to price. When bought, the plant is consigned to the scrap heap as soon as possible, and something up to date installed in its place. Thus the absurdity of a hard-and-fast rule. Authorities who would act are prevented, and companies who see existing failures are unable to obtain powers to improve matters. A point that will tend to clear matters with regard to tramway work and assist the deliberations of the Joint Committee on Municipal Trading, is that the London County Council seem to accept the statement that "their tramway undertaking must distinctly be considered a trading institution." Such was Mr. Beachcroft's admission at the Council meeting on Tuesday, when the question was raised as to the giving of evidence before the Joint Committee. Once get such admission generally received, the ground is cleared for a

Digitized by Google

definition of what comes within the scope of municipal action, and what constitutes trading. It is no reply to say certain authorities make a good profit on their trading. We have long since advocated the view that authorities ought not to carry on undertakings for the purpose of making profits, and gladly see this view being adopted by some of the witnesses before the Joint Committee. In trading, a possible profit includes a possible loss, and it is certain the keenest advocates of work for profit-making will be less keen if the probability of loss is equally great. Of course, it is always best to prophesy on a certainty.

THE NEW OWENS COLLEGE PHYSICAL LABORATORIES.

[BY OUR OWN CORRESPONDENT.]

There is a well-known political maxim that "What Manchester says to-day, England will say to-morrow." Manchester has just spoken, with no uncertain voice, on the subject of the improved scientific education of her residents, and has proved, both by practical example as well as by precept, by the readiness with which its wealthier magnates have disbursed themselves on behalf of the science schools and colleges in their midst, and by the keenness of the interest they have shown in providing the best possible education for their sons, in the best possible surroundings, and with the best possible appliances and teachers. This has been splendidly illustrated by the circumstances which have attended the building and equipment of the new Owens College physical laboratories, and which were opened on Friday last by Lord Rayleigh with all the pomp and ceremony and formalities which are the common adjunct of these occasions, and in the presence of a large and distinguished assemblage of scientific gentlemen from all parts of the world.

The occasion marks an epoch in the history of physics in this country, for now for the first time can we point with proper pride to an institution at all comparable in size and efficiency as an educational instrument to the best and largest laboratories of the Continent and of America. In point of size, the new laboratories are the largest in the United Kingdom, and stand fourth in the world's list, of which the Johns Hopkins, Stuttgart, and Darmstadt laboratories are respectively first, second, and third; while in the means for carrying out extensive research, and in the possession of apparatus and appliances of the highest and most perfect kind, its position will be even nearer the top of the list. A walk round the various rooms cannot fail to raise in the minds of everyone who is able to recall the facilities, or, rather, the want of facilities, of 20 years ago for carrying out elaborate experiments in physics an unholy feeling of envy, to be immediately followed, however, by one of congratulation and contentment at the superior advantages which the next generation will receive.

We hope to describe at full length in an early issue these laboratories and their equipment. Some conception of their nature may be gathered from the following brief description. The buildings, which are of red brick outside, with fire and glazed brick inside, are situated in Coupland-street, on a plot of ground opposite to the main college buildings, with which it is connected by a subway. It contains four floors, including the ground floor, and a basement. Broadly speaking, the ground floor contains all the research rooms. It will also be provided with means for the testing of commercial instruments, as current meters, wattmeters, etc. Leading off from a door on this floor is the John Hopkinson memorial laboratory, a handsome, well-lighted, and splendidly ventilated brick building, built and presented by the relatives of the late Dr. John Hopkinson, to be devoted to the study of electro-technics in all its branches. The equipment of this Hopkinson wing was presented by the friends of John Hopkinson, and will include, by the beginning of next session, a 20-h.p. to 25-h.p. continuous-current motor, for driving half the shafting; two six-pole shunt-wound 18-kw. E.C.C. generators combined on the same base-plate, and fitted with collector rings for multiphase currents; one 18-kw. Hopkinson alternator; one 3·5-kw. alternator, supplying either single, two, or three-phase current as required. In addition to these, the laboratories have been presented with 30 Chloride cells and 30 Tudor cells, the total capacity at normal discharge rate being about 300 ampere-hours. In the electro-chemical laboratory are installed a large electric furnace of the Moissan type, taking about 500 amperes, and suitable benches and tanks for electro-chemical research. The first floor of the main building is to be devoted to the elementary and advanced laboratories for elementary students, and those taking the ordinary and honours course in physics. The second floor contains the lecture-rooms, the largest of which is capable of comfortably accommodating 210 students. Leading from the second floor is a staircase to the observatory, which contains a large 10in. refracting equatorial telescope, presented by Sir Thos. Bazley. This is mounted on a stone pillar running down into the ground and entirely separate from the main floor of the observatory. Another important feature of the buildings is the large Rowland grating ruled on a 6in. surface to above 100,000 lines. The mounting for this grating was specially designed by Sir Howard Grubb, F.R.S.

There was a large and brilliant attendance on the occasion of the opening of the new Owens College physical laboratories on Friday last by Lord Rayleigh, F.R.S. Mr. Alderman Thompson (treasurer of the college) presided, and amongst those present were Sir W. Abney, Sir W. Roberts-Austen, Sir Thos. Bazley, Sir H. Roscoe, Profs. J. J. Thomson, S. P. Thompson, Perry, Armstrong, Jack, Rücker, Lodge, Ludwig Mond, and Pickering (Harvard), and Mr. Wm. Mather.

Mr. Alderman THOMPSON, in opening the proceedings, said that the study of the physical sciences had become so interesting and so engrossing that the college had been compelled to erect this new building, and to fit it with the best possible appliances.

Principal HOPKINSON said that the erection of the laboratories was first rendered possible by the two magnificent donations of £10,000 and £5,000 respectively, given by friends of the college who desired to remain anonymous, the one towards the cost of building and the other to the endowment. Donations had been also received from others, and numerous gifts had been made by many engineering firms of the district. A grant of £500 had also been made by the Lancashire County Council, and a sum of £5,000 had been given by the executors of the late Mr. Harling for the founding of a research fellowship in physics or electro-technology in memory of that gentlemen.

Lord RAYLEIGH, in declaring the laboratories open, said that, as an old friend of Prof. Schuster, he was pleased to be able to participate in the ceremonies of the day. Twenty years ago they were associated in some work on electrical units, which they then brought to a satisfactory conclusion. It was hardly credible to many of those who studied electricity at the present time, that 20 years ago the ohm was uncertain to as much as 2 per cent. Speaking as a middle-aged or an elderly man, he could not help at first an unholy feeling of envy and jealousy on looking at the buildings which had been erected mainly through Prof. Schuster's labours, whose career he had watched with admiration, and with a sincere appreciation of his width of knowledge and soundness of judgment. He himself had attended with the utmost enthusiasm the lectures of Sir George Stokes at Cambridge, but there there were no facilities for personal experiment. Apart from the work which might contribute to actual scientific advance, there was also the humbler and more useful practical work by which the students acquired some knowledge of the realities described in their text-books. Phrases were liable to be repeated in an unintelligent manner when there was nothing to illustrate the meaning. A child is said to have defined the equator as a "menagerie lion running round between two poles." That might be an extreme case; but all were slaves to phrases which were only partly understood, and it was undoubtedly true that a student who went through a course of practical physics acquired an idea of what he was doing

Digitized by Google

and talking about that could never be satisfactorily got from books, or even from attending experimental lectures. They had been told that these laboratories owed much to the munificence of Manchester men. He had no doubt that in the future the benefactions of Manchester men would be called upon again. Besides providing a laboratory, there were constant demands for extensions and for increased staff and appliances. He could not help thinking that in America the rich men entered more fully into their duties than had often been the custom in England. A story was told of the president of an American university who had frequently received help from a certain wealthy magnate in the city where the university was situated, and who paid another call with a similar intention. The wealthy magnate said, "I have no time to talk to you; I know what you want. Here's my cheque-book; fill it up." He looked forward to the future of the laboratory with great hope. They had a professor who had already done much, and from whom much might be still reasonably expected. He thought that anyone occupying Prof. Schuster's position should be relieved of as much routine work as possible. He concluded by declaring the laboratory open—an assertion which would not be disputed—and by wishing it all the prosperity and the success which it deserved.

Prof. SCHUSTER, in moving a vote of thanks to Lord Rayleigh, said that the whole history of the college showed that one of the main objects of Owens College was, on the science side, to provide that high type of technical work which meant the training up of men who should not only supervise the work done in our workshops and factories, but who should also go on to fresh discoveries and the advancement of knowledge. No doubt it would be necessary ultimately to separate the subject of technical electricity and pure electricity, with separate professors, but he thought there was a certain charm in a place where the theoretical and practical parts were so closely united. He abhorred the remark which one heard so frequently, that a thing may be all right in theory but it was wrong in practice. It was altogether wrong to say this. A thing might be wrong in theory, or the practice may be imperfect, but what was right in theory could not possibly be wrong in practice. Alluding to the new John Hopkinson building, Prof. Schuster announced that an anonymous friend had given £500 towards completing the equipment of this wing.

Sir HENRY ROSCOE seconded the motion. He said that when he first came to Owens, in 1857, he found not only no means of practising physics in the laboratories, but neither was there any means of lecturing in physics. Looking round the buildings, he could not help repeating a remark of the late Lord Derby's, that "England is always late, but she's never too late."

The resolution was carried with acclamation, and this terminated the proceedings.

A pathetically sad, but highly interesting, ceremony next took place in the new John Hopkinson laboratory, to which most of those present at the principal ceremonies adjourned. Alderman John Hopkinson, on behalf of the relatives of the late Dr. John, presented formally the new buildings to the college, to be known as the John Hopkinson Department of Electrical Engineering. In a speech that was full of pathetic references, Alderman Hopkinson said that the relatives hoped that the facilities now given for the study of applied science might help Prof. Schuster in his important work, and that under his supervision a "Manchester school" of electrical engineering should be established second to no other. Manchester was proud of her distinguished son, and rejoiced with his family in his successes, and mourned with them in the early termination of a life so full of beneficent energy and of promise of yet larger results. They hoped that his example and career might enter with living power into the work of the students within those walls, and fulfilling the old motto of the Institution of Civil Engineers, "To use the forces of nature for the benefit of mankind." Mr. Alderman Thompson gratefully accepted the gift on behalf of the college. Mr. W. Mather, M.P., then formally presented the equipment of the Hopkinson laboratory on behalf of a few friends and admirers of the deceased. Prof. Rücker and Prof. Jack bore independent testimony of Dr. John's greatness, the one as a man of science, the other as a mathematician, and the proceedings then closed.

THE TRAMWAYS AND LIGHT RAILWAYS EXHIBITION.

(Continued from page 916, Vol. XXV.)

Passing from the exceedingly interesting exhibit of the British Westinghouse Company, one naturally turned to the combined exhibit of Messrs. Dick, Kerr, and Co., the English Electric Manufacturing Company, and the Electric Railway and Tramway Carriage Works. This combined exhibit consisted, in the first place, of track work of various kinds, the rails being of different weights, and suited for all kinds of roads. Poles and brackets for overhead trolley work were also exhibited. Naturally, the portion of the exhibit which one noticed most were the electric cars. The first of these was a large car for heavy service, and built to seat 64 passengers. Like others of the cars exhibited, this one was fitted with the Bellamy reversed staircase. This staircase, instead of starting from the side of the platform from which the passenger alights or gets on the car, is taken across to the other side. The improvement is, no doubt, very good when one gets used to it, but a moderately tall man is rather apt to spoil his hat on the apparatus which informs people in the street of the car's next stopping place. This last-named apparatus is certainly an improvement to the extent that at a fair distance one can see by the lamps placed behind opal glass the name of the car's destination. The tramcars are mounted on maximum traction trucks, and the motor equipments of the cars shown are of Messrs. Dick, Kerr, and Co.'s standard type, and are fitted with a special solenoid blow-out controller. The bogie cross-bench car for summer service which was shown is similar to that used on the Blackpool and Fleetwood tramway. These tramcars are mounted on equal wheel bogie trucks, and have an overall length of 40ft. 3in. and a seating capacity of 65. The seats on the car shown were very comfortable, and had a good type of reversible back. The improved Preston single-deck car shown was of a similar type to a number which the English Electric Manufacturing Company have built for Messrs. Dick, Kerr, and Co. It is very nicely fitted, and has a very neat and graceful appearance. The motor work is similar to that on all the cars which were in this exhibit. The brakes used are pneumatic, and are worked with an axle-driven air-compressor. Apart from the car exhibits was shown a standard type of truck fitted with motors and air brakes, and also various motors and controllers made on the Short system, and of the kind usually used in the construction of the tramcars. A motor-driven compressor for working the air-brakes was also shown.

The British Thomson-Houston Company, Limited, exhibited quite a quantity of apparatus of the type used in the latest pattern for electrical tramway construction. In the first place, two large tramcars, properly fitted up, were exhibited. The one which would be of particular interest to those who have lately seen the progress made with the construction of the overhead line in the western suburbs served by the London United Tramways Company, Limited, would be the car made for use upon those lines. The car was very roomy and comfortable, and was built to the designs of Mr. J. Clifton Robinson, the managing director of the above-named company. These cars are built to accommodate 69 passengers—30 inside and 39 out. Communication is made with the driver by means of small bell-pushes. The lighting is carried out by means of electrical incandescent lamps, which are rendered more effective by being placed behind cut-glass globes. The trucks are of the Peckham bogie type, and the electrical equipment consists of two of the exhibiting company's B. & L. motors of 28 b.h.p., mounted one on each truck on the axle of the larger wheels. Electric brake controllers, lightning arresters, circuit breakers, etc., are fitted. The trolley arm is of the upward pressure type, mounted on internal springs in the trolley standard. It is placed on one side of the car, a seat for one passenger only being used in order to make room for it. The other car, a standard Hurst-Nelson reversed stairway car, was very

Digitized by Google

similar to the London United car, except that, probably intended to be used only for show purposes, it was fitted up in a very handsome, though extravagant fashion. The trucks on this car, however, were of the Brill maximum traction type, and the electrical equipment was of the standard British Thomson-Houston double G.E. 58 motor electric brake equipment. In order to freely show the electric equipment, a Hurst-Nelson truck with extension springs was exhibited, on the axles being mounted two G.E. 58 motors with enclosed gear cases. The truck was placed so that the wheels could revolve and actual working conditions be shown. The motors used were especially suitable for heavy service, and could be used on both standard and narrow gauge tracks. The armature could be wound with either a four or six turn winding, the horse-power given being 37 b.h.p. and 27 b.h.p. respectively. The motors were connected to a series-parallel magnetic blow-out controller of the rheostatic brake type, so as to show the effectiveness of the rheostatic electric brake. These controllers are used for controlling the direction of rotation of the motors as well as the amount of current they take, there being less current consumed when the motors are connected in series than when they are connected in parallel, the latter being used where the cars are run at high speeds, while the former connection is used for starting, slow running, and frequent stopping. The operation of the rheostatic brake is secured by connecting the motors in such a manner as to convert them for the time being into generators, and thus transforming the kinetic energy stored up in the car by virtue of its rapid motion into electric energy, which is dissipated in suitable resistances in the motor circuit. This transformation of energy is so rapid that an exceedingly effective retardation of the car is obtained, the amount being entirely within the control of the motorman. The controller is further provided, like all British Thomson-Houston controllers, with a magnetic blow-out, in order to reduce the cost of maintenance and repair to minimum. In making the changes from series to parallel there is produced at the terminals of the controller fingers an arc, which if not instantly extinguished will soon roughen, and eventually volatilise the metal that the contact fingers are composed of, but which the magnetic blow-out "blows out" before it has an opportunity of doing the slightest damage. A number of automatic circuit breakers were shown, and also some standard resistance boxes. A trolley was arranged to show that the upward pressure was uniform throughout its whole range. Amongst the other exhibits by this company were electric car heaters, tramway recording meter, material for overhead construction, magnetic blow-out lightning arresters, and a specimen portion of track fitted with the centre slot type of underground conduit. A specimen of surface-contact system was also shown.

The principal exhibit which the Brush Electrical Engineering Company showed was a bogie vestibule car. This car is of an overall length of 39ft. 6in., and is divided into two compartments, the entrance being in the centre. In this way one half of the car can be used for smoking if desired. The car is naturally only a single-decked one, but it is very well fitted, and is arranged with sliding windows similar to those of railway carriage doors. The exhibit, however, which was newest was that of the controllers made by the Brush Company. The first, the H.G. 2, was a series-parallel controller fitted with an emergency electrical brake and return current position. By means of this controller the weight of the car descending a gradient is utilised to generate a current and return the energy to the line. The other controller shown was a series-parallel controller with a rheostatic brake, and by which the speed of the car can be easily reduced either gradually or, on emergency, suddenly. The motor which was shown was a 25-h.p. four-pole iron-clad motor with ventilated armature and laminated pole-pieces, and having the field coils wound on brass spools, which allow of easy renewal. The bottom half of this motor is made to hinge downwards, either with or without the armature bearings.

The J. G. Brill Company, of Philadelphia, U.S.A., had an exhibit which consisted of a tramcar, trucks, etc. The tramcar which was shown was a single-decker and entirely self-contained, in that it could be used for winter or summer use by either pushing up or pulling down the sides and windows. The sides and windows are carried in the roof, and are easily operated. The car shown, which was similar to those built by the Brill Company for the Leeds Corporation, was very well fitted inside, the benches being seated with cane in imitation of the old style of rush-bottom used in chairs. The backs of the seats are reversible. There were also three type of trucks exhibited, amongst the distinctive features of which were the absence of bolts and the use of solid forged side-bars, separate specimens of the latter being shown. Models of trucks in bronze were shown, and a gong worked by the motorman's foot.

The Electric Construction Company exhibited a 70-kw. variable-ratio transformer, as used in the Oxford system, and an alternating-current transformer of the E.C.C. standard pattern, in which the iron circuit is composed of circular discs, by which means the loss is reduced to a minimum. Magnetic leakage is also reduced by splitting up the winding into a number of sections. A 30-h.p. tram motor and a stationary Bushbury enclosed motor were also shown, this latter being constructed to stand an overload of 100 per cent. for short periods. A standard generator was shown, and also a specimen of the company's trolley for side suspension, in which the trolley head is fitted with a cushion spring to absorb shock. Switches and a generator panel were also included in the exhibits, and also a generator panel with an automatic cut-out and field regulator.

Messrs. W. T. Glover and Co., Limited, naturally exhibited cables; a case of samples of various kinds and sizes, lead covered, steel armoured, etc., was shown, and also various joint-boxes. In this portion were straight, tee, and four-way junction boxes for single, concentric, triple-concentric, twin, and three-core cable of all sizes. Rail bonds also formed part of the exhibit of this company, these having both round and compressed strands.

The British Insulated Wire Company showed specimens of their cables as in use in the various towns of Great Britain, and also the system of laying the same. The St. Helen's Cable Company were also amongst those exhibitors who showed specimens of cables.

(To be continued.)

THE ENGLISH ELECTRIC MANUFACTURING COMPANY'S WORKS.

AN OBJECT LESSON.

(Concluded from page 922, Vol. XXV.)

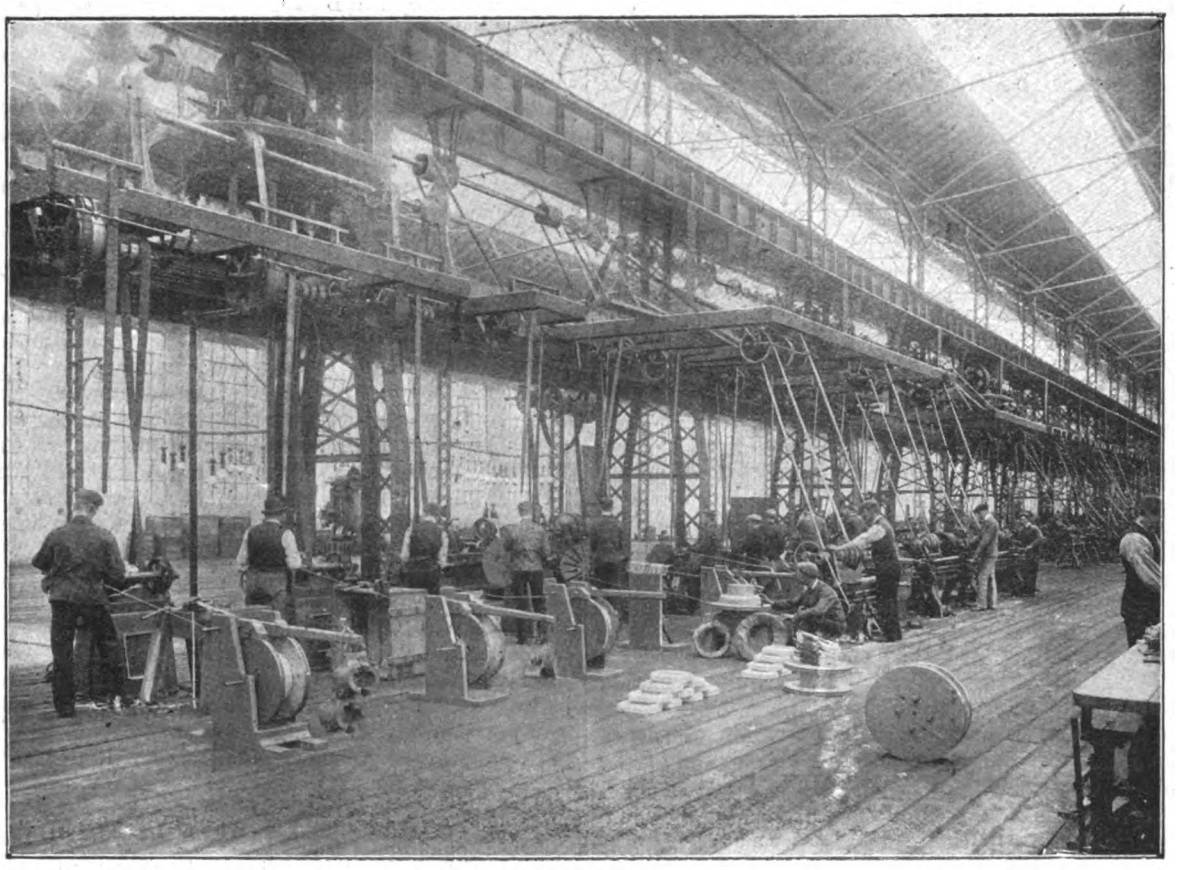
Offices.—In the south-east corner of the machine shop are placed the offices on the ground floor, the engineering department occupying the first floor with a thoroughly equipped laboratory for testing all materials entering into the finished product. The drawing offices and a very complete photographic department are on this floor. Both the offices on the ground floor and the engineering department are provided with large fireproof strong rooms for books and drawings. On the second floor the company has provided clubrooms, consisting of reading-rooms and library, dining-room, and kitchens for the use of the works' staff.

Foundry.—The foundry building is parallel with the machine shop, with a space of 60ft. between the two. It is 465ft. in length and 120ft. wide. It is equipped with two 30-ton and one 15-ton electric crane. In this building are contained the ironfoundry, the brassfoundry, the pattern shops, and the pattern storage shops. Two cupolas are provided for moulding iron and five brass furnaces for making the brass parts for motors, generators, and switchboards. The ironfoundry will be used for making the frames of the very large generators and alternators for the manufacture of which these works are specially equipped. In both the brass and iron foundries the machine tools provided are driven by an independent motor. These special tools are used for sifting sand, for cutting gates from castings, for cleaning and finishing castings after they come from the sand, and for magnetically separating brass and iron filings which may be returned from the machine shop. The pig iron and coke

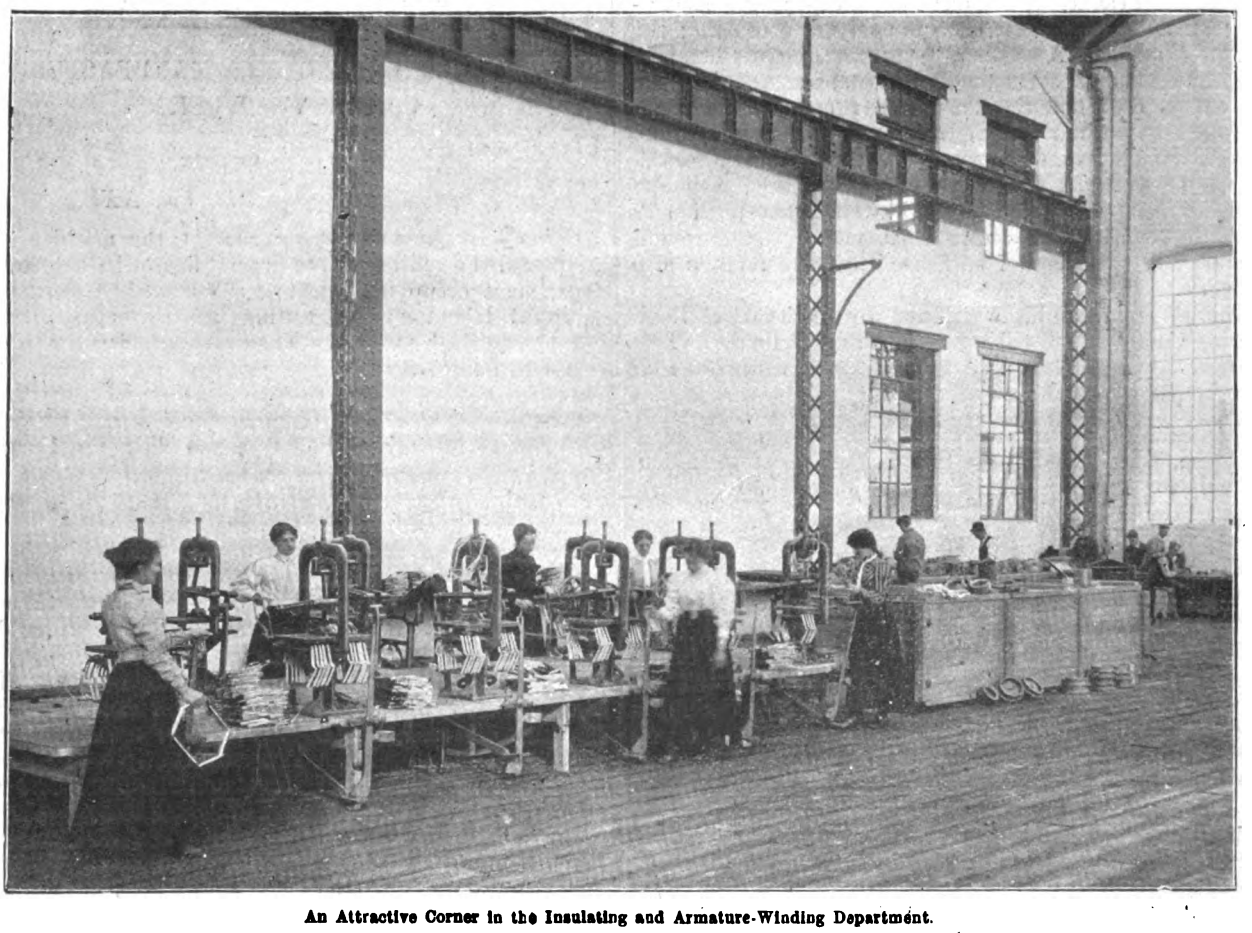
Digitized by Google

for charging the cupolas is delivered directly from the railway tracks upon the left cupola staging on the same level with the cupola charging doors. Here 600 tons of iron can be stored, with coke enough to melt it, and the cupolas charged without lifting or handling of material. The pattern shop is provided with its own motor and a complete equipment of the best wood-working tools.

Power-House.—The power-house is at the south end of the foundry, with a clear space of 30ft. between the two. It is 144ft. long, 120ft. wide, divided into a cold-storage room, boiler-room, engine-room, battery-room, and reservoir.



Winding Department.



An Attractive Corner in the Insulating and Armature-Winding Department.

The boiler-room contains at present three 500-h.p. Lancashire boilers, with ample space to receive an additional three boilers of the same capacity. A Green's economiser

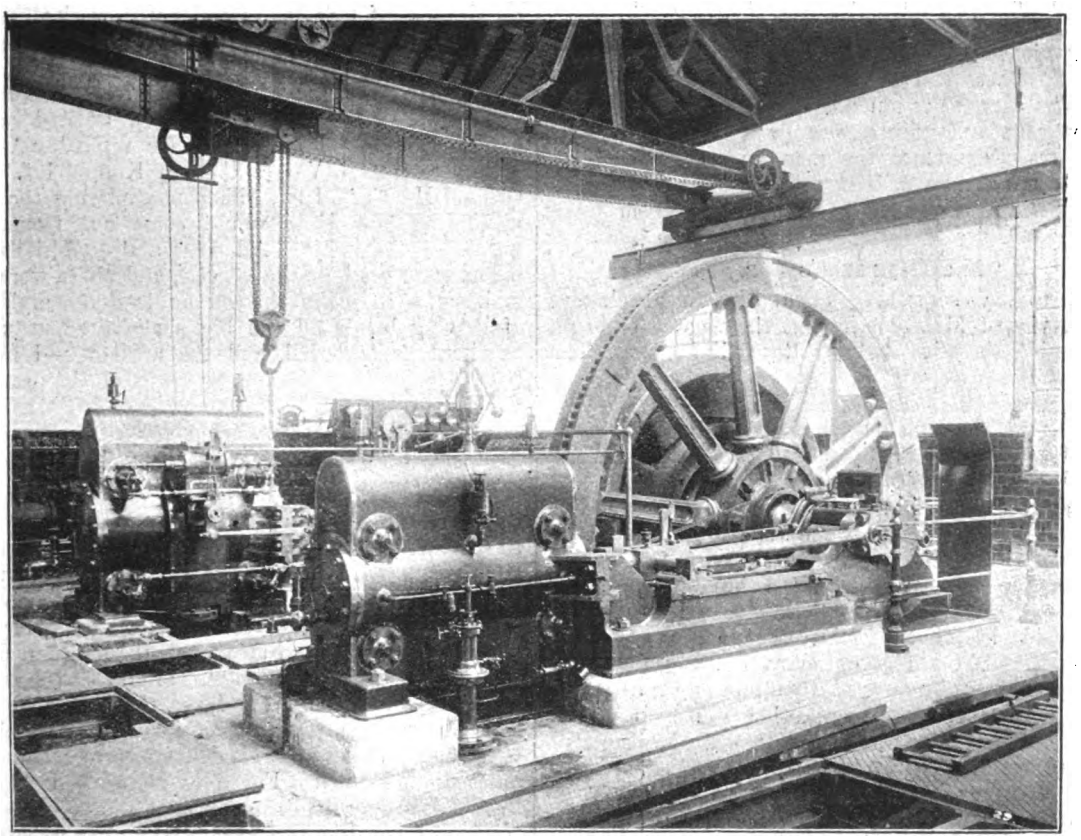
Digitized by Google

is provided, together with the necessary boiler feed pumps. The engine-room at present contains two cross compound Corliss engines, each direct connected to a generator of 400 h.p. capacity. There is therefore available at the present time 800 h.p., with a possible overload capacity of 25 per cent. Space is left to receive a 1,000-h.p. unit which will shortly be installed, and the generator for which will be made at these works. The battery-room contains a 500-volt Chloride accumulator set, which is used for supplying light and power throughout the works at night when the power plant is shut down. The reservoir, with a capacity of 60,000 gallons of water, receives its supply from an elaborate system of roof drains. A cooling tower erected over one portion of the reservoir cools the water coming from the condensers of the engines.

Lighting and Heating.—All the buildings and grounds are lighted most thoroughly, for the general lighting arc lamps being used with incandescent lighting suitably arranged for the individual tools. The heating and ventilation of the buildings is amply provided for, so that the temperature can be kept uniform at any point from 60deg. to 70deg. F. throughout the year. In the offices the direct radiating method is used, while for the shops the hot-air system is employed, accomplishing the double purpose of providing not only for heating, but for an adequate supply of pure air at all times.

General.—Within the grounds there has been erected what will be known as the directors' clubhouse, provided with a dining-room, kitchens, bedrooms, etc., for the accommodation of the directors and their friends while remaining overnight at the works. Special attention has been paid not only in the laying-out of the plant itself, but in other directions for the comfort and means of entertainment of the workmen in the shops. Alongside the foundry it is arranged that extensive bathrooms will be erected, provided with hot and cold plunges, etc., and in which each of the men employed in the foundry will have his own special locker reserved for his private use. A portion of the company's funds is being devoted to the erection of a large group of comfortable workmen's dwelling-houses upon an excellent site close at hand to the works. It is also intended to erect a large clubhouse with gymnasium and reading-rooms, etc., for the men. In this connection it may also be added that the directors of the company, recognising the important part which the young engineer with a fair technical education and a sound practical training has played in the building up of the industry in connection with the great German and American companies, have in view, for the benefit of such young engineers employed at the works, the delivery of a regular course of lectures on electrical engineering subjects throughout the year, this being a matter to which Mr. Short himself attaches the greatest possible importance as a factor in the continued future success of the undertaking.

Is it not Bain who says that when two pleasures concur, the result is a greater pleasure? and we presume the summation goes on correspondingly with more than two. Hence the pleasure of those interested in these works ought to be great. They have taken a leaf out of the book of their competitors; in fact, they have gone one better—they have remembered the mutual dependencies between labour and capital, and they have started successfully with orders. If pleasure is not derivable from every-one of these sources, it ought to be. Our thanks are tendered to the directors and officers who so fully and freely opened their works for inspection, and who were indefatigable in giving information, and we trust a successful opening may be followed by a long and successful existence.



View of Engine-Room and Overhead Travelling Crane.

FIELD TELEGRAPHY AT MAFEKING.

The following article, written by the war correspondent of the *Pall Mall Gazette*, appeared in that journal on the 28th ult. By the kind permission of the editor we are allowed to reproduce the same in full, and we concur heartily in the writer's appreciation of the good work done by the electrical engineers of Mafeking. It will be seen from the article that these gentleman had to "make bricks without straw," and that they did not despise the methods of the Dutch in the way of commandeering. No English Postmaster would dare to do what Messrs. Howat, Campbell, and Simpson did, and we are pleased to see a record in the Press of the appreciation of these gentlemen's services. The article in question reads as follows:

"Some departmental workers in the field are seldom heard of by the general public, and, therefore, do not come in for the share of praise for work done that should be theirs. Yet these departmental corps form the principal springs that work the war machine. Without a com-

Digitized by Google

missariat department an army could not take the field. It could not bring its necessaries with it, and would find itself in a corner for want of food. The Royal Engineers are seldom sung about, and few know how hard the scientific corps work to make everything possible for the conduct of operations. Is there a mountain to be removed? They do it. Does the general want to have a system of telegraphs constructed, or a railway built, or an engine driven, or a bridge thrown across a river, or a sea of timber cut down? The Royal Engineers are the men upon whom falls the work, and nobody can say that the corps does not perform it in the highest state of efficiency. Those corps that do the heaviest and most laborious duties are, as I have said, the bodies that are least heard of at home. They toil like galley slaves, but quietly; and when their toils are over little more is heard about them until they are required in some other part of the field. The public mind must be stimulated into interest by sound and dash. A blazing battery or mass of guns rattling and dashing over a plain to get into action comes first in public favour; the cavalry, with sabre in hand or lance-point dropped, scouring over the plain after a retreating enemy, come next; and patient, swearing Tommy of the infantry of the line, with his bayonet fixed and his helmet on his ear, poking his way into an enemy's trench, is generally a good third. These are the fellows of noise, glitter, and dash; but you cannot get much dash out of half a mile of transport wagons and mule teams or a system of useful telegraph wires. Therefore the men who work that part of the show must take a back seat, and be content to make up with the extra daily salary given them by a thoughtful War Office.

"MR. CAMPBELL'S JOB.

"I want to say something about the telegraph and telephone service of Mafeking during the siege. To begin with, we had little wire and no Royal Engineers. The postmaster of the place, Mr. J. B. Howat, had the planning of the arrangements in his hands, and Mr. Arthur Campbell, of the Belfast Telegraph Department, with Mr. J. B Simpson, of the Northern Relief, had the arranging and thinking and 'bossing up.' Miles of wire had to be laid to all the furthest forts and works, and the question was how to begin. As a start, all the telephones rented by the townspeople were taken down and the wires and instruments commandeered. With these a humble beginning was made, and an efficient field system was completed across the veldt in all directions. The wire was carried on small pegs raised a foot or so over the ground, and passing cattle and carts improved the lines and caused the staff to sing Watts's hymns and other items of sacred music. By-and-by, it was discovered that all the insulated wire that had been laid with much trouble under fire was wanted for the purpose of connecting mines to blow the enemy up with. Down came the lines again, and Campbell had to go around gathering all the scraps of wire that he could find in the town, tie them together, and endeavour to stretch 100 yards into 10 times that length. Metallic circuits were out of the question, as they would have necessitated the use of double the quantity of line. Earth circuits were formed, and the earth-plates consisted of iron buckets filled with mud, and rolls of zinc that had been shelled off the roofs in town. Occasionally a wire end was fixed to an iron rail on the top of a bomb-proof shelter, and that acted as well as anything else.

"DIFFICULTIES OF CONSTRUCTION.

"Everything was nicely settled as far as it went, and the telephone headquarters was established in the local post office, until it was found that it would be more convenient at the staff headquarters, a quarter of a mile away, and subsequently in the headquarters dug-out around the corner. Each of these shifts meant the taking down of the instruments, the elongation of the wires, and the fixing up of the instruments again. As new works were formed at the front, and our lines of defence were thrown out farther and farther, the demand for lines of communication became more frequent, and longer lines had to be established. The construction party went grey through thinking of their load of work and wondering where they would get the wire. At last somebody made a splendid find in the shape of thousands of yards of manganese wire, which the inmates of the gaol were told off to insulate by wrapping calico around it and tarring it over. Eureka! the difficulty was solved. At home a heavy storm or a big snow does damage to your lines, and causes the maintenance staff to use bad language. Here in Mafeking we had no snow, but the showers of iron were too much for the wires. Scarcely were we ever shelled but they were smashed, and the men had to go out under fire to set them right again. Times innumerable the cutting was done by Mauser bullets, and once during a heavy wind a tin roof sailed off a house in the market square, and of course, fate willed that it should fall right on the entire system of wires and fracture them. It was a warm moment when Mr. Campbell and his staff came out to count up the damage.

"MR. MACLEOD.

"Night and day that network of wires had to be watched and the instruments nursed like babies, and the work of repairing was never done. Many a time and oft in the darkness of the night the men were on the poles connecting up when the bullets began to whiz around them and make them shin their way to the ground again, and once MacLeod, the drawling fat Scotch ex-sailor who worked as linesman, was almost blown off the post by a shell. He seemed to work 20 hours out of the 24, but I only heard him growl once. He was sitting on a kerbstone, looking up with tired eyes at two wires that were twisted around each other, and when I hailed him he replied, 'A-a-h-h, mon, look y-o-o-nder. Y-o-n's Cannon Koppie lyin' d-o-o-n on Colonel H-o-r-e.' I left him contemplating the wreck, and wondering how Hore would come out from under the weight of the kopje. All sorts and conditions of instruments were used in the service, and there were numerous makeshifts to make the communication complete. Pieces of driving bands off the big shells fired at us made an excellent switchboard, and the ancient and modern contrivances found in the lumber-room of the post office were hauled out and fixed in the trenches to do duty for receivers, transmitters, and alarms.

"THE COMMUNICATION DEPARTMENT.

"This communication department was without exception the most severely worked body in Mafeking. In addition to erecting and maintaining under the most terribly trying circumstances, they had to work the instruments or train others to work them; they had to keep watch and watch and at the same time run the siege post office. Human nature could not stand that kind of thing indefinitely, and in course of time the postmaster and all the hands except Campbell went sick with fever, the result of exhaustion and other ailments, and then for weeks Campbell had to take the watches of all his colleagues and run the department single-handed. For days he worked 24-hour shifts, but he did not die, as many men would have done. On the top of his troubles came the siege surcharged stamps. Everybody wanted sets and new issues and particular stamps to make up their collections, and his bomb-proof post office was each morning beseiged by waiting crowds clamouring for mauve sixpennies, yellow sixpennies, sixpennies with the figure in a reclining position, and sixpennies with the 'elongated figure.' I often went over there to watch his labours and admire his patience. There is a law in nature by which a man finds rest while contemplating the toiling of another, and the sight of this brain-weary man leaving the dug-out to look after his duties elsewhere had a delicious, balmy effect. I admit the savagery of the idea!

"I wrote in a dispatch of the great rains that washed us out of our trenches. During those rains the telephone instruments suffered. They were submerged, and when the holes were baled out the receivers and transmitters were found to be full of mud. Even in this supreme trial the patience of the amazingly patient men did not desert them. They began to clean out the mud with no hope of ever being able to make sound go through the telephones again; and at the finish were surprised to find that they had once more got their machines into perfect going order.

"It will be well if telephone and telegraph people at home cut this out and read it twice each time that a snowstorm or a gale gets among their wires."

THE POWER BILLS.

On Tuesday last the Select Committee on the Electric Power Bills met to consider the clauses of the three Bills—*i.e.*, the Durham Bill, the Lancashire Bill, and the South Wales Bill—the preambles of which were declared proved on the 28th ult. Before commencing the consideration of these clauses, Sir JAMES KITSON made the following statement, which is an expansion of the declaration of the committee already given respecting the South Wales Bill: (1) The company to be authorised to supply electrical energy for power purposes anywhere within the area of supply subject to the consent of the local authority in certain cases as set out below. (2) The company to have no general lighting powers—*i.e.*, distribution to ordinary consumers—within the area except in pursuance of a provisional order obtained in the usual way. (3) where a local authority is now authorised to supply electricity within the area, their consent is to be required to the supply of electricity by the company. The Board of Trade to be empowered to override the refusal of the local authority to give consent if the authority are not prepared to provide the requisite supply on reasonable terms and within a reasonable time. (4) Any local authority who hereafter gets statutory powers for supplying electricity within the area to have in ordinary cases the option of taking over the company's supply in its local area on terms to be laid down by the provisional order or Act, by which the statutory powers are given. (5) A company having statutory powers to be in the same position as a local authority now having statutory powers, a company to whom powers are hereafter granted to be placed in the same position as a local authority to whom statutory powers are hereafter granted. Sir James Kitson also suggested that the Government draughtsman should meet the agents to go through the clauses before the next meeting of the committee.

Mr. E W. FRERE, respecting the Lancashire Bill, said that he did not see anything in the above statement which would apply to the Lancashire Bill. The insertion of the clauses suggested for limiting the South Wales Bill would be extending the powers the promoters of the Lancashire Bill asked for.

Mr. PRITT said the same applied to the Durham Bill.

The committee on Wednesday considered a clause prepared by the Board of Trade in reference to the South Wales Bill, which clause was finally adopted in the following form: "The powers of the company for the supply of electricity under this Act shall be subject to the following provisions: (1) Electricity shall be supplied under this Act only (*a*) for supply in bulk to authorised distributors and (*b*) for the purpose of providing power and for the lighting by any person to whom it is so supplied for power of any premises in any part of which the power is utilised. (2) Electricity shall not be supplied under this Act by the company in any area being at the passing of this Act the area of supply of any authorised distributors, except with the consent of those distributors, but that consent shall not be unreasonably withheld. If any question arises whether that consent is unreasonably withheld or not, that question shall be determined by the Board of Trade. The consent shall be deemed to be unreasonably withheld if the authorised distributors are not willing and in a position to give the requisite supply upon reasonable terms and within a reasonable time, and, in considering what are reasonable terms and what is a reasonable time, the Board of Trade shall, amongst other things, have regard to the terms upon which, and the time within which, the company are willing and in a position to give the supply. (3) If at any time after the passing of this Act any local authority or company become authorised distributors in any area within the area of supply under this Act, the company shall be subject to any provisions which may be made by the Act or provisional order under which the distributors become authorised as to the taking over of any supply then given by the company for use exclusively within the area of supply of the distributors. (4) Nothing herein contained shall prevent a company from applying for provisional orders under the Electric Lighting Acts of 1882 and 1888. (5) Nothing in this section shall authorise a company to supply electricity for lighting other than the lighting specially mentioned in this section. In this section the expression 'authorised distributors' means any local authority, company, body, or person authorised by Act of Parliament or provisional order confirmed by Parliament to supply electricity within the area of supply."

The committee adjourned.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

285. In applying the pressure test to transformers, say with 6,000 volts between the primary winding and the secondary winding, core, and earth shield, and with 2,000 volts between the secondary winding and the core and earth shield, what reason is there for joining the primary winding to core and shield in the latter case?—C. W.

286. Should high-tension mains for, say, 6,000 volts be laid in cast-iron troughs in preference to wood? And if so, why?—J. R. W.

ANSWERS.

Question No. 280.—Describe and sketch a consumer's double-pole fuse-box to carry up to 50 amperes, which has the following qualifications: (1) the box or boxes to be of cast iron, with glass front, and cover which can be removed quickly; (2) fuses easy to renew; (3) no thimbles to sweat on to cables; (4) good insulation between poles and from earth; (5) arrangement for sealing; (6) cheap—not more than 10s.

Best Answer to No. 280 (*awarded* 10*s.*).—The house service fuse box as shown in the sketch, which is to scale, is a single-pole fuse, and therefore applicable to three and five services, as well as for two. The case is of cast iron, and the dimensions are for a fuse capable of taking 50 amperes at pressures up to 250 volts. It has some improvements over the ordinary type of service fuse, notably the horizontal position of the screws that secure the fuse, the locking arrangement of the same, and its very high insulation from earth, also the double-grip cable terminals. The advantage of having the fuse terminals horizontal will be obvious: it allows the fuse to be slipped in quite easily and screwed up with a wrench in an easy position, and if the meter board is fixed underneath a shop window or in a coal cellar, it will not necessitate the performance of an acrobatic feat to avoid coming in contact with some of the other apparatus with the other end of the wrench. The sketch shows plainly the locking arrangement of the fuse terminals, and is marked F and E (Fig. 3), and H (Fig. 1). By the way, the wrench should be provided with a screw-driver end for tightening up the screw F (Fig. 3). The cable terminals, as shown at A (Fig. 3), are as reliable as a sweating thimble. They have two nipping screws each, which will make doubly sure of having no loose connections. The burning of the rubber covering of the cable is utterly avoided, and therefore it is not necessary to rewind with tape. Where the cable enters at the top of the box, it should be wrapped with some kind of tape so as to exclude dirt; the bottom cable can be left loose, which will ventilate the box. The fixing screws, as shown at F (Fig. 1), should be well sunk into the porcelain division piece, marked E (Fig. 1). This division should reach nearly to the top of the fuse box—it will then baffle any arc formed by a fuse blowing; it should be divided, so as to allow the fuse wire to pass through. In some of the fuses now on the market

Digitized by Google

the fixing screws are placed very close to the current-carrying parts, and are therefore a constant source of surface leakage to earth. The door, which is shown by dotted lines in sketch, is furnished with a pair of hinges at D (Fig. 1); it is secured by means of a brass pin passing through the three ears at G (Fig. 1). This pin should have a small hole in one end for seal wire to be passed through. In the centre of this door is a small window, I (Fig. 1), for inspecting the fuse wire. The case is lined with a piece of vulcabeston sheet, which is secured in place by slipping it between the sides of the case and the porcelain base. The door is also lined with a piece of the same material. The fuse wire should be of copper, with end plates of copper sheet (see Fig. 2); this will keep the fuses well away from the door.

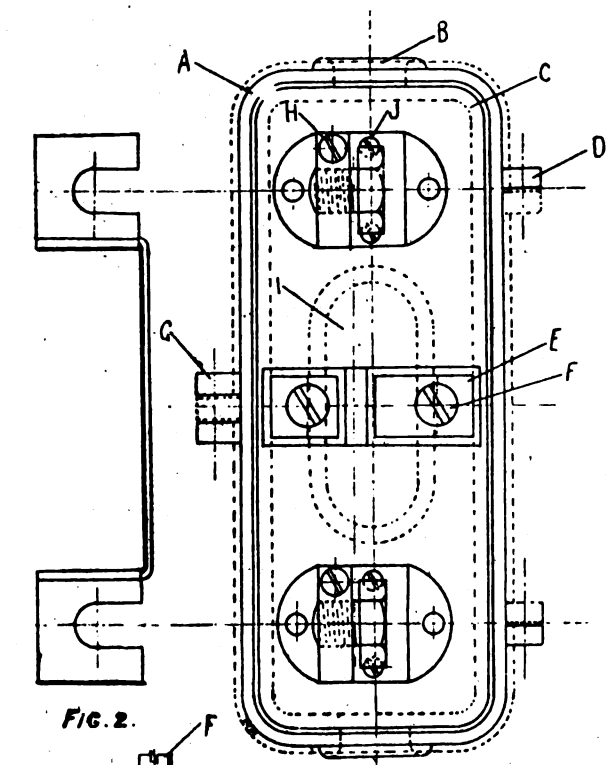

FIG. 1.

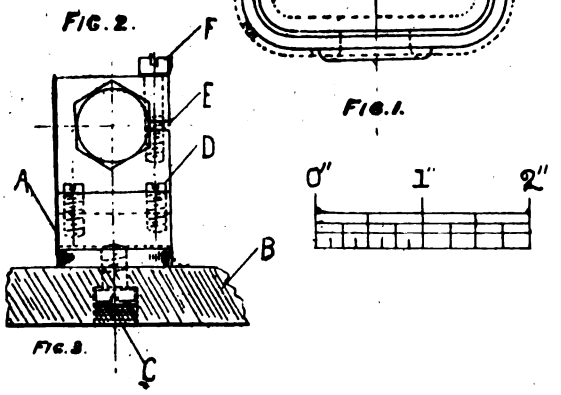

FIG. 2.

FIG. 3.

The letters on the drawings denote the following parts: Fig. 1—A, cast-iron case; B, hole for entry of cable, preferably bushed with ebonite; C, china base; D, hinge; E, china division; F, fixing screws; G, door fastener; H, fuse terminals locking screw; I, glass door; J, cable-nipping screws. Fig. 3—A, hole for cable $\frac{5}{16}$ in. diameter; B, porcelain base; C, shellac; D, cable-nipping screws; E, sawcut for clamping arrangement of fuse terminal; F, clamping screw.

I think the above will meet the requirements. The price will come within what is named for a pair if they are manufactured in any quantity.—W. B. DALE.

Answer to No. 280 (*awarded* 5*s.*).—General arrangement of consumer's double-pole fuse box is shown in Fig. 1. Box is of cast iron, lightly made, and provided with lugs at the corners for fixing, and with holes bushed with wood or fibre to admit the service cables and house wires. The poles are separated by a partition of common roofing slate dropped into a groove, formed by casting two parallel ridges down sides of box as shown. Contacts are mounted on porcelain blocks screwed to the back of box at the four corners. The lid has a glass front, and is easily removed. Fig. 5 shows back view and section of lid. Fig. 6 shows simple arrangement for sealing. On the lid and box two lugs are cast, so arranged that with lid in position these lugs lie one over the other (Figs. 4 and 6). To seal the box, a piece of string is passed through a hole drilled in each lug, tied on the top, and the wax dropped on the knot

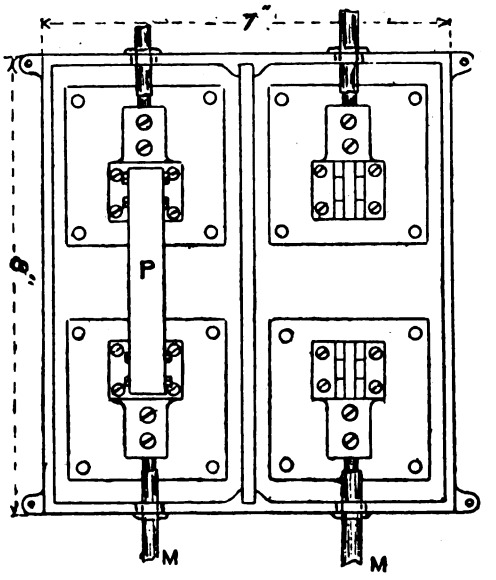

FIG. 1.—General Arrangement of Fuse-Box

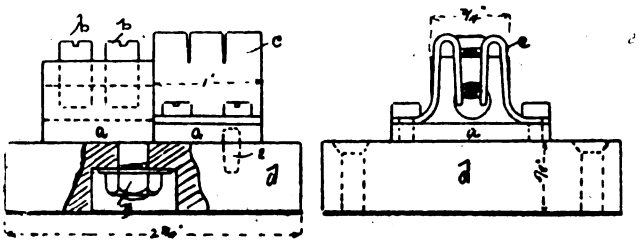

FIG. 2.—Detail of Contact.

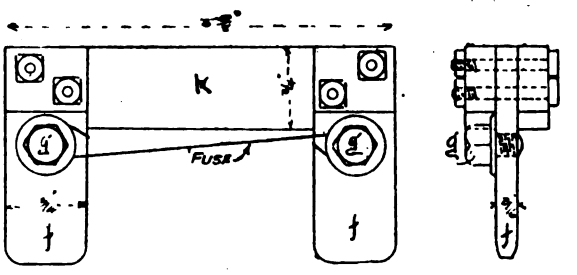

FIG. 3.—Detail of Plug.

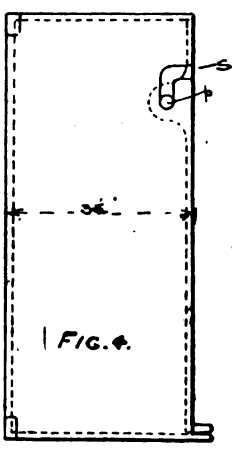

FIG. 4.

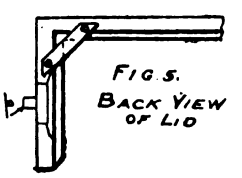
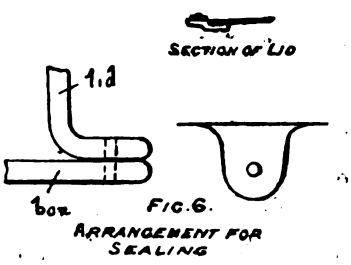


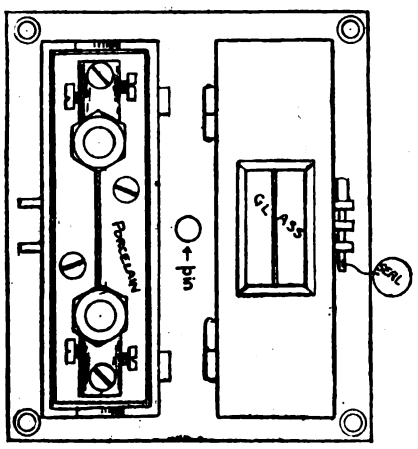


and stamped. To remove cover the lid must be swung forward at the bottom (the dividing partition is made to allow this) and lifted upward until pin, *p* (Figs. 4 and 5), is brought out of right-angled slot, *s*. The lid is then free. The form of contact is clear from Fig. 2. The brass casting,

Digitized by Google

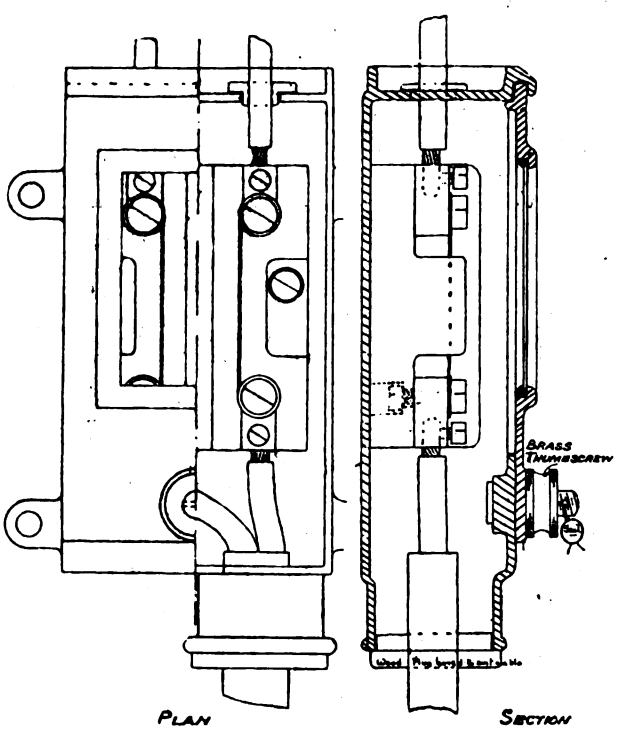
a, is drilled to receive the cable, which is held firmly by the set screws, *b b*, which have the same diameter as the hole, thus making the contact as secure as possible. On the broadened end two spring clips, *c*, are fastened as shown. The whole is held to the block by nut, *n*, and side movement prevented by steady pin, *e*. The recess may, if thought necessary, be run up with sulphur. The arrangement of the plug fuse is shown in Fig. 3. A stout fibre bar is recessed at each end, and into these recesses are bolted two brass contact pieces, *f f*. The fuse is stretched across as shown, being held at each end by set bolts, *g g*. Fig. 1 shows one plug, P, in position, the other being removed. To replace fuses the plugs are withdrawn by means of the fibre bar, *k*, the fuse wire stretched across as shown, and the plugs again inserted. The above arrangement is as cheap as it is safe to go, if convenience, mechanical strength, and durability are factors entering into the consideration of the question.—P. S. T.

Answer to No. 280 (*awarded* 5*s.*).—The sketch shows plan of a fuse-box arrangement which answers to the above specification: (1) The boxes are mounted on a base of varnished wood with their hinges facing one another, so that the opening of one box prevents the other one being opened. Between the boxes is a wooden pin upon which the opened cover rests. (In the sketch one cover is taken



off its hinges.) To open a box, simply cut the seal off and pull out steel pin. A glass front is provided for inspecting fuse. (2) The fuse wire is twisted around a brass bolt (part of thimble) and secured by a nut and washer. (3) Thimbles are provided with several set screws for securing cable, but there should be no slackness in fit where sweating is not allowable. (4) Excellent insulation is secured by using glazed porcelain slabs $\frac{3}{4}$in. thick. Care should be taken to fill up the screw head holes at the back of the slabs with paraffin wax. The porcelain fixing screws go through holes in the bottom of the box and fasten in the wood base. It is assumed that single rubber or diatrine service cables are used in damp situations, and that the boxes are bored to fit their outside diameters. (5) Seals are fixed on the end of steel pins threaded through lug holes cast on top and bottom halves of boxes, as shown. (6) The cost is under 10*s*. The arrangement is Reason type.—J. H. C. B.

Answer to No. 280 (*awarded* 5*s.*).—The accompanying sketch of a house fuse box fulfils all the conditions laid down. The shell is of cast iron. The lid, which has a glass front, is quite separate, but is rigidly held by the brass thumbscrew. A hole for sealing is provided. The porcelain base is screwed to the cast-iron shell, but has a thin sheet of mica placed between it and the shell. The fuse terminals are mounted on the porcelain base. At one end of each terminal a hole is bored to take the house or service cable, which is firmly held by a screw. No sweating is required. At the other ends screws are provided which fasten the fuse wire. There is a wall of porcelain between each pole and the sides of the box. Additional features of this box are: Suitable compound may be run on to the top of the box, and will prevent moisture getting in down the leads. The lower part of the box can be filled to level of terminals with compound after the service cables have been attached. This will effectually prevent moisture getting into the insulation, and makes the box suitable for



use with paper or jute insulated cables. The cost should not exceed 10*s*.—L. H. E.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

King's Lynn.—The Corporation invite tenders for extensions to the electricity station at the old waterworks. Tenders by July 9.

Bermondsey.—The Vestry invite tenders for the erection of a generating station in Neckinger, Spa-road. Tenders by 26th inst.

Manchester.—The Corporation invite tenders for alterations required to the existing wiring at the Victoria Hotel. Tenders by 10th inst.

Croydon.—The Council invite tenders for the building of an electricity sub-station at Pollard's-hill North. Tenders by 12th inst.

Croydon.—The Council invite tenders for the erection of car sheds at the Thornton Heath and Brighton-road depôts. Tenders by July 18.

Beckenham.—The Urban District Council invite tenders for Section G, free wiring contract. Tenders by July 16. Details in our advertisement columns.

London, N.E.—The Electric Lighting Committee of the Hackney Vestry invite tenders for the supply of 220 arc lamp pillars. Tenders by July 11.

Edinburgh.—The Corporation invite tenders for the supply of copper strip for electric conductors. Tenders by July 9. Details in our advertisement columns.

Rochdale.—The Committee of the Rochdale Municipal Technical School invite tenders for the wiring, etc., of the Rochdale Technical School. Tenders by 14th inst.

Lowestoft.—The Corporation are prepared to receive tenders for meters (direct-current) and cut-outs. Tenders by 10th inst. Details in our advertisement columns.

Southend-on-Sea.—Tenders are invited for the supply and delivery of about 1,180 tons of steel girder rails and about 46 tons of steel fishplates. Tenders by July 25.

Huddersfield.—The Corporation invite tenders for the overhead equipment of two short sections of tramways (total length about 2 miles 300 yards). Tenders by 9th inst.

Huddersfield.—The Corporation invite tenders for excavator, mason, and bricklayer's work in the construction of a conduit from the electricity works. Tenders by 9th inst.

Croydon.—The Town Council invite tenders for the reconstruction of the present tramway track and the construction of new tramways and paving of roads. Tenders by 10th inst.

Madrid.—The Secretary for Public Works invites tenders for the construction and working of an electric tramway from Puerto de Hierro to Aravaca and Pozuelo. Tenders by July 7.

Birkenhead.—The Corporation invite tenders for constructing and erecting a new car shed in connection with the electric tramways in Laird-street, Birkenhead. Tenders by July 24.

Newport (Mon.).—The Corporation invite tenders for the construction of a double line of tramways along Corporation-road

Digitized by Google

(length about 1½ miles), and other incidental works. Tenders by 9th inst.

Algemesi (Valencia, Spain).—The Municipal Authorities will receive tenders for the installation and working of the electric lighting by July 21. Specifications may be inspected at this office.

Tunbridge Wells.—The Corporation invite tenders for the supplying, laying, and jointing of armoured telephone cables; also instruments, etc. Tenders by July 12. Details in our advertisement columns.

Huddersfield.—The Electricity Committee invite tenders for a single-phase steam generating plant, having an output of about 1,000 kw. Tenders by July 12. Details in our advertisement columns.

Leeds.—The Tramways Committee of the Leeds Corporation invite tenders for supplying and fixing two, four, or six steel boilers (Lancashire type) at the generating station, Crown Point, Leeds. Tenders by July 9.

Wimbledon.—The Urban District Council invite tenders for supplying and fixing telephones intercommunicating between the various buildings forming the isolation hospital. Tenders by 18th inst. Details in our advertisement columns.

Beckenham.—The Urban District Council invite tenders for the erection of brick transformer stations, 11ft. by 11ft. in size internally, and six in number, the sites of the stations being at various points in the district. Tenders by July 9.

Cardiff.—The Corporation invite tenders for the manufacture of about 1,000 tons of steel tramway rails; also for fishplates, sole-plates, tie bars, bolts and nuts, points and crossings, drain rails, copper rail bonds, etc. Tenders by July 12.

Salford.—The Corporation invite tenders for the supply, delivery, and erection of the overhead equipment for the tramways in the borough, exclusive of the steel poles, but inclusive of their erection. Tenders by July 16. Details in our advertisement columns.

Hammersmith.—The Electricity and Lighting Committee invite tenders for the supply and delivery of insulated high and low-tension cables, junction boxes, etc., cast-iron pipes, drawbox covers, etc. Tenders by July 12. Details in our advertisement columns.

Southend-on-Sea.—The Corporation invite tenders for the supply and erection of boilers and auxiliaries, steam generators and switchboard and cranes, feeders and distributors, line equipments, trucks and car equipments. Tenders by July 25. Details in our advertisement columns.

Islington.—The Electric Lighting Committee invite tenders for relaying York and other stone and providing new York and other stone where necessary over the conduits and mains, as required, during the three years next. Tenders by 25th inst. Full details in our advertisement columns.

Blackpool.—The Corporation invite tenders for the following works in connection with tramways extension: (Section A) trolley poles; (B) cables and trolley wires; (C) boosters and switchboards; (D) storage battery. Tenders will be received for any one or more sections, but not for part of a section. Tenders by July 23.

Madrid.—The Spanish Government invite tenders, not later than Aug. 18 for the concession of a system of electric tramway lines in Barcelona. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between 11 a.m. and 5 p.m.

Partick.—The Commissioners invite tenders for the supply and laying of insulated electric mains, conduits, junction-boxes, etc., the supply and erection of cast-iron arc and incandescent lamp standards, arc lamps, automatic switches, and other fittings. Tenders by July 10. Full details in our advertisement columns.

South Shields.—The Guardians invite tenders for the complete installation of the electric light at the union workhouse, Harton, South Shields. The proposed works consist of (Section A) engines, dynamos, battery, and main switchboard; (B) wiring, cables, and fittings. Tenders by July 14. Details in our advertisement columns.

Grays Thurrock.—The Council invite tenders for the supply, delivery, and erection of two Lancashire boilers and pipework, two 100-kw. steam dynamos, with boosters and balancer, fuel economiser, switchboard, battery, travelling crane, and mains and street lamp fittings. Tenders by Aug. 9. Details in our advertisement columns.

London, S.W.—Tenders are invited for the supply, within three months of the order being given, of about 70 arc-lamp standards, required in connection with the electric light installation for the Victoria-embankment, for the London County Council. The standards are to carry the lamps suspended, at about 23ft. from the ground level, at the end of a curved arm extending over the carriageway. Each person tendering is to submit his own design for the standard, or, if he so desire, he may submit alternative designs. A short description of the standard, showing generally what is required, may be obtained at once on application to the Clerk to the Council. Specification may be obtained at the Engineer's Department, County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on July 10.

Durban.—The Corporation invite tenders for supply, delivery, and erection of materials under the three following sections: (Part A) comprising the supply, delivery, and erection of the entire overhead equipment for about 16 miles of equivalent single track, including poles, overhead trolley wire, distribution boxes, etc.; (B) comprising the supply, delivery, and erection of 22 double-deck motorcars, complete; (C) comprising the supply and putting into working order of a complete steam and electric generating plant in a power station to be built by the Corporation, including three 250-kw. direct-coupled generators, boilers, condensers, cooling tower, switchboard, etc. Parts A and B will not be separated, but will be let to one contractor. Part C may be let separately. Preference will, however, be given to a contractor who will undertake all three sections, and a separate form of tender for all three sections will be supplied. Specifications, bills of quantities, forms of tender, and lithographic drawings may be obtained on application to Messrs. Webster, Steel, and Co., 5, East India-avenue, Leadenhall-street, London, E.C., agents to the Durban Corporation. A deposit of £10. 10s. must accompany application for specifications and forms of tender. The deposit will be returned on the receipt of a bona fide tender. Sealed tenders, in duplicate, under separate cover, in specially-provided envelopes, to be delivered to the Town Clerk of Durban by mail delivery on or about July 23. The successful tender will be accepted by cable from Durban.

RESULTS OF TENDERS.

Keighley.—The tender of Mr. T. E. Sugden, for the erection of municipal electricty works, at £3,260, has been recommended for acceptance.

Blackpool.—The Corporation have contracted with the British Thomson-Houston Company for the supply and erection of 15 electrical tramcar equipments.

Tower Wagons.—The Blackburn, Darwen, and Poplar Electricity Works have given orders for telescopic tower wagons and ladders to Messrs. J. H. Heathman and Co., London.

Dover.—The Electricity Supply Company have obtained the Corporation's order for the illumination of the sea-front the same as last year on the same terms, £45 for the installation and £20 per week for current.

Manchester.—The tender of Messrs. Macartney, M'Elroy, and Co., of London, for the electrical equipment of three tram routes in the city has been recommended for acceptance. The contract is for £16,251. 6s. 6d., and covers the cost of providing the overhead and other traction appliances for Cheetham Hill, Rochdale-road, and Bury New-road routes (about 10 miles).

West Ham.—The Guardians have accepted the tender of Messrs. Frank Suter and Co., Limited, 66, Berners-street, W., at £5,252 (subject to the sanction of the Local Government Board), for the execution of the following separate contracts: (1) supplying and laying cables and wiring the buildings and premises, and supplying and fixing the lamps, switches, and all other necessary fittings; (2) supplying and erecting the plant complete, including storage battery, switchboard, instruments, and engines and dynamos in duplicate.

London, S.E.—The Bermondsey Vestry have received the following tenders for the supply and laying of insulated electric mains, conduits, junction boxes, etc.:

W. T. Glover and Co., Salford (accepted)	£8,134	7	9
St. Helens Cable Company, Warrington	8,109	16	8
Siemens Bros., Queen Anne's-gate, S.W.	8,113	9	11
Callender's Cable Company, 90, Cannon-street, E.C.	8 212	7	1
Western Electric Company, North Woolwich	8,219	11	11
British Insulated Wire Company, Prescot	8,643	15	10

London, W.—The Directors of Madame Tussaud and Sons, Limited, have received the following tenders for an extension of their electric lighting plant. The specification for this included two 30-kw. steam dynamos, two Babcock and Wilcox steam-boilers (each with 526 square feet of heating surface), switchboard, and connecting cables:

Johnson and Phillips (own dynamo, Alley-Maclellan engine)	£1 775
Crompton and Co. (own dynamo, Willans engine)	1,963
Crompton and Co. (own dynamo, Reavell engine)	1,722
Bruce Peebles and Co. (own dynamo, Willans engine)	2 158
Bruce Peebles and Co. (own dynamo, Browett-Lindley engine)	1,948
Bruce Peebles and Co. (own dynamo, Reavell engine)	1,928
Bruce Peebles and Co. (own dynamo, Alley-Maclellan engine)	1 918
Drake and Gorham (Parker's dynamo, Willans engine)	2 058
Christy Bros. and Middleton (Crompton dynamo, Browett-Lindley engine)	2,126
Christy Bros. and Middleton (Crompton dynamo, Willans engine)	2,154
Christy Bros. and Middleton (Crompton dynamo, Reavell engine)	1,924
Christy Bros. and Middleton (Crompton dynamo, Allen engine)	2 116
J. H. Holmes and Co. (own dynamo, Willans engine)	2 150

The tender of Messrs. Johnson and Phillips was accepted under guarantee to deliver and erect one steam dynamo in eight weeks. The tender of Messrs. J. Simpson and Co., Pimlico, was accepted at the same Board meeting for the supply of the steam and exhaust pipes, feed pumps, feed heater, calorifier, and all the necessary apparatus to enable the exhaust steam to heat the building on the system of the Atmospheric Steam Heating Company. The amount of this tender was £560. Mr. R. W. Weekes, M.I.E.E., A.M.I.C.E., is the consulting engineer for the work.

Johnstone.—The Council are in communication with the promoters of the Tramway Bill in Parliament in reference to certain adjustments.

Digitized by Google

BUSINESS NOTES.

TRACTION.

Fleetwood.—The Corporation propose to spend £9,300 on new electric tramcars.

Manchester.—The Corporation have come to an agreement with the Manchester Carriage and Tramways Company.

Dundee.—The construction of the proposed tramway between Dundee and Monifieth appears now to be a settled matter.

Bournemouth.—At a special meeting of the Council on Monday, it was resolved that the parliamentary agent be instructed to proceed with the Corporation tramways order.

Lincoln.—At the last meeting of the Town Council it was stated that the Tramways Bill had now advanced so far that it was beyond opposition. The scheme would not be other than successful, and would be a revenue-producing scheme.

Middlesex.—The County Council resolved on Thursday last week to persevere in their opposition to the Bill of the London United Tramways Company when it comes before the House of Lords. The attitude of the Council is severely criticised in the local Press.

Gloucester.—Mr. Alfred Dickinson, of Birmingham, who was formerly general manager and engineer of the Birmingham Tramway Company, has been asked to report generally upon the negotiations now pending between the tramway company and the Corporation.

Gravesend.—The Town Council will oppose the application to be made to the Board of Trade by the National Electric Traction Company, Limited, for an extension of time for the commencement of the works authorised by the Gravesend, Rosherville, and Northfleet Tramways Order, 1899.

Swansea.—The local paper states that an alternative route is proposed for the Swansea Corporation tramways, powers for the construction of which are now being sought. This, if carried out, would deviate the published route, and result in an important and valuable new street being opened up.

Kirkcaldy.—At a meeting of the Town Council on the 2nd inst. the report of Prof. Kennedy in connection with tramways and electric lighting for Kirkcaldy was discussed. The matter was remitted back to a committee to consider and report the relative cost of the alternative routes proposed.

Blackpool.—The Town Council have decided to oppose the Blackpool, St. Annes, and Lytham Tramways Bill when it comes before the House of Lords Committee. It is thought that clauses are now being introduced in the Bill respecting the supply of electricity to the company that are inimical to the interests of the Corporation.

Lyndhurst.—The Council are considering favourably a proposal with regard to the construction of an electric tramway and electric lighting for Lyndhurst. Mr. C. J. Wharton, Westminster, has been over the proposed route, and his suggestion is to construct a line commencing at the Lyndhurst-road railway station to Lyndhurst. Electric current would be available for public and private lighting.

Glasgow.—The tramways report for the last year shows a continued increase in every item. In consequence of the introduction of electric traction on parts of the system there is a gain of 2·45d. per tram mile in receipts, and a saving of 2·55d. in expenses. It is expected that fares will be lowered again when the conversion of the system is completed. In the contemplated urban extensions Paisley, Clydebank, and Renfrew are included.

Bolton.—It is stated that the makers of the cars have promised to deliver the cars on order within the next three months. In regard to the resignation of the tramways manager and electrical engineer on his appointment to a similar position at Cardiff, it was suggested at the last Council meeting that separate managers would be appointed for the two departments, and that the dual management system hitherto adopted would be abolished.

Southport.—The Board of Trade inspection for the electric tramways is fixed for July 17, and the formal opening of the tramway service for the following day. Last Friday the first official trial over the completed parts of the route was undertaken upon the one car that has recently arrived from Preston by members of the Electricity Tramways Committee, other members of the Town Council, and various officials connected with the work.

South Staffordshire Tramways.—The South Staffordshire Tramway Lessee Company have formally taken over the working of the whole of the tramway systems of the old South Staffordshire Tramways Company, and we learn that the management will remain in the hands of Messrs. H. Hatchett and J. J. Robins. The former will still retain the secretaryship of the old South Staffordshire Company, which position he has held for the past 15 years.

Aston.—At the last meeting of the Council a letter was received from Sir R. Nicholson, stating that the Parliamentary Committee are prepared to recommend the County Council to limit its opposition to the London United Tramways Bill to clauses, if the District Council will consent to the County Council being the purchasing authority of the whole of the tramways proposed to be authorised by the Bill. A motion not to accede to the wish of the County Council was passed.

Aberdeen.—At the meeting of the Town Council on Tuesday a recommendation of the Tramways Committee to the effect that Councillor Wilkie (convener of the committee), Mr. Moonie (superintendent of the tramways), and Mr. Bell (electrical engineer) be delegated to visit the International Tramways and Light Railways Exhibition in London to examine the latest apparatus designed for the equipment of mechanical tramways and light railways, both surface and underground, was agreed to.

Derby.—The Tramways Committee were authorised on Tuesday to prepare a scheme of electric tramways and extensions for submission to the Council for their approval, and to apply for parliamentary powers in the ensuing session through the Parliamentary Committee. A resolution to instruct the Tramways Committee to arrange for the discontinuance of the Sunday traffic on the tramways at the earliest possible moment was brought forward, but the motion, after some discussion, was negatived.

Portrush.—At Monday's meeting of the Urban District Council Mr. H A Macaulay, solicitor to the Council, submitted a consent entered into between the Portrush and Giant's Causeway Tramway Company and the Urban District Council, by which both parties agreed to a settlement of the action raised by the Council against the tramway company to obtain an injunction restraining the latter from obstructing the streets at Portrush by the poles carrying the overhead electric wires, the Council to pay the costs as between party and party. The costs amounted to about £70.

Liverpool.—The electric lines having now been completed in Prescot-street, the old route will be put in use immediately. Rapid progress is being made with the electric equipment in the London-road districts, and Mr. Bellamy expects to have the electric cars running by the August bank holiday. The laying of the rails on the Wavertree route is proceeding, and when this portion is finished the eastern section will have been completed. The dispatch with which the work has been carried out is very favourably commented upon.

Wimbledon.—At last week's meeting of the Council the report of the Tramways Committee was adopted containing the surveyor's report upon the proposed tramway between Wimbledon and Tooting, and also plans showing three schemes as under: (1) tramways laid as a single track, except between Miller's Mead and Terrier's Bridge; (2) tramway laid as a double track, with lines interlacing throughout; (3) tramway laid as a double track, except between Miller's Mead and Terrier's Bridge. The Croydon Rural District Council will be asked to appoint a committee to form with the Wimbledon committee a joint committee for the purpose of considering the schemes submitted by the surveyor.

Hampstead.—At the meeting of the Vestry on Thursday last week a letter was received from the hon. secretary of the committee formed to oppose the Haverstock-hill and Hampstead Heath tramway scheme of the London County Council, expressing their best thanks to the Vestry for their prompt and unanimous refusal of consent to the application of the Council for permission to construct such tramway. Sir Henry Harben, chairman of the Vestry, drew attention to the danger of accepting a single penny from any company, omnibus or otherwise, towards any widening or improvement scheme. He hoped this Vestry would discourage any payment whatever, and adopt any action that might be decided upon entirely on public grounds.

Blackpool.—At the meeting on Tuesday a clause in the Electric Lighting Committee's minutes dealing with the committee's visit to the London Electrical Exhibition, was objected to on account of the large number of members who proposed to go away at the expense of the ratepayers. It was proposed that the clause be referred back, the Mayor pointing out that the Corporation contemplated spending £100,000 on tramway extensions, and it was only right that the committee should see that they got the very latest and best. The reason why the whole of the committee were invited was because very few could promise that they would be able to go, and, in reality, only seven undertook the journey instead of 20. The clause was accepted.

Carlisle.—Mr. A. P. Trotter, inspector of the Board of Trade, inspected the electrical plant of the Carlisle tramway system last Thursday. He also visited the electric lighting station in James-street. The inspector expressed himself generally satisfied with what he had seen. There will be a formal Board of Trade inspection of the permanent way, Mr. Trotter's duties being confined to the electrical plant, which will probably not interfere with the starting of the tramways for the service of the public. The company intend to use 12 cars, nine of the double and three of the single-deck description, which have been built by the Electric Railway and Tramway Carriage Works Company, Limited, Preston. After the inspection the inspector and other guests were entertained at luncheon at the County Hotel by the tramways company.

York.—At the meeting of the City Council on the 2nd inst. a resolution was carried providing for the giving of notice to the City of York Tramways Company, Limited, requiring them to sell so much of their undertaking within the city as is authorised by the York Tramways Order, 1879, and all lands, buildings, plant, etc., used by them in connection with it; and for application being made to the Board of Trade for their approval to the Council giving the notice. The minutes of the Streets and Buildings Committee, which were adopted at the ordinary meeting of the Council, contained a report on the subject of the tramways by the town clerk, stating that, according to cases decided in the House of Lords, the price to be paid was the value of the tramways as measured by what the cost of construction would be at the date of sale, subject to a proper deduction for depreciation, and not on the basis of a rental valuation. Neither the amount of the capital of the company nor the goodwill was taken into consideration.

St. Helens.—At the meeting of the Council on Wednesday the Mayor moved the adoption of the minutes of the Electric Supply and Tramways Committee, and gave a brief sketch of the progress of matters electrical as worked by the Corporation. On March 31, 1898, he said, 4,526 lamps were connected, and the cost to produce the current was 4·04d. per unit, and the total cost 6d., while the sale was over 35,000 units to 63 consumers. In 1899 they had 6,463 lamps, the works cost had dropped to a little over 3d., the total cost to rather less than 4½d., and 65,091 units were sold to 79 consumers at the price of 6d. At the end of March this year they had 13,981 lamps connected, the works cost had gone down to less than 1d., and the total cost to nearly 1½d. The sale was 320,160 units, which, of course, included that supplied for the tramways. The number of consumers was 190, and there had been an increase in the supply for motors. The output for May was 57,434 units, which was at the rate of 689,800 units per annum, or about double the output last year. Seeing that May was one of the lightest months in the year the increase was most promising. A profit of £10. 12s. 7d. had been made last year, but this would be increased next year. In spite of difficulties and the changing over from the Warrington Old-road station, there had been no serious failure in supplying electricity. The minutes were confirmed.

Northwich.—On Friday a deputation, consisting of Major Tulloch, R.E., Mr. H. W. Handcock (electrical engineer), Mr. John Parnell, C.E., and Mr. Walter J. Lomax, C.E., waited upon the Rural District Council for the purpose of conferring with them respecting the proposal of the United Kingdom Tramway, Light Railway, and Electrical Syndicate, Limited, London, to construct a line of tramways connecting Northwich, Middlewich, and Winsford. The matter was fully discussed, and a resolution favourable to the scheme was passed. The deputation also met the members of the Winsford Urban District Council, and explained to them the proposals of the system of tramways. Mr. Prince Lewis presided, and there were also present Messrs. T. Massey, S. Leach, R. Chesters, J.P., Jackson, J. M. Dean, J. H. Cooke (clerk), H. Hulse (surveyor). The deputation explained the scheme, after which the following resolution was passed: "The Urban District Council of Winsford, having heard the explanation of Major Tulloch and Mr. Handcock, of the United Kingdom Tramway, Light Railway, and Electrical Syndicate, hereby express themselves as generally favourable to the scheme of tramways connecting Northwich, Winsford, and Middlewich, as suggested by the explanation given, subject to the details to be submitted to a future meeting and agreement being arrived at between the Council and the syndicate. The Council further consider it most advisable that the line of rails should approach the town by way of Wharton-road."

LIGHTING AND GENERAL.

Leeds.—The salary of Mr. Street, electrical engineer, is to be increased by £100 per annum.

Chelsea.—The surveyor is now making experiments in the use of motor-vans for sweeping, etc.

Belfast.—The Council propose to apply for sanction to a loan of £95,000 for electric light purposes.

Finchley.—Circulars are being issued to the ratepayers asking if they desired to have the electric light.

Mexborough.—The electrical engineer has been instructed to proceed with the work of lighting the town by electricity forthwith.

Padstow.—The Lighting Committee is about to make enquiries as to whether the town can be advantageously lighted by electricity.

Charlton.—The Blackheath and Greenwich Electric Light Company propose to lay down a main along the Old Charlton-road very shortly.

East Grinstead.—The Urban District Council have decided to interview Mr. Elvey Robb, of Tunbridge Wells, with reference to the electric lighting.

Limehouse.—The electric lighting provisional order of the Board of Works will come before the committee of the House of Commons on the 16th inst.

Gloucester.—It is stated that the trial run of the electric light in the shops is highly satisfactory. The official opening of the works will take place next week.

Lewes.—The transfer of the Lewes Electric Lighting Order, 1898, to the County of Sussex Electrical Power distribution Company, Limited, has been completed.

Wakefield.—Mr. H. P. Boulnois held an enquiry on Wednesday into the application of the City Council to borrow £25,000 to extend their electric lighting scheme.

Cheltenham.—Colonel W. R. Slacke, R.E., has held an enquiry into the application of the Town Council for sanction to borrow £20,100 for purposes of electric lighting.

Pickering.—The Urban District Council on Monday decided to meet representatives of an electrical supply company to discuss the merits of electricity for public lighting.

Coventry.—Stock is to be raised, subject to the approval of the Local Government Board, for a quarter of a million sterling. This amount includes £33,671 for electric lighting.

Ilford.—A temporary loan of £10,000 for electric lighting purposes has been obtained. The foundation stones of the electric lighting station and the chimney shaft will be laid shortly.

Southport.—Colonel A. J. Hepper, R.E., has held an enquiry into an application of the Town Council to borrow £9,000 for the provision and laying down of continuous-current cables. There was no opposition.

Friern Barnet.—The District Council are greatly concerned about the increase in the charges for gas, and it is suggested that they will shortly have to be seriously considering the introduction of electric lighting.

Leicester Electricians.—It has been officially reported by the War Office that the Leicester members of the Electrical Engineer Detachment, Royal Engineers—Messrs. D. F. Colson, A. Charlton, and G. Charlton—are prisoners.

Halifax.—The Electricity Committee of the Town Council have agreed that the salary of Mr. H. F. Street, the electrical engineer, be advanced on Oct. 1 by £100 per annum, and at the expiration of 12 months from that date to £500 per annum.

Leamington.—The Town Council have decided to make an offer to the Midland Electric Light Company of £17,000 for their undertaking outside the order, the offer to be subject to the order obtained in 1900 being transferred to the Corporation.

Wrexham.—Tenders for the boiler-house for the destructor in connection with the electric light works will be invited on a specification to be prepared by the borough surveyor. Provision has been made at the waterworks for an electric motor and pump.

Kidderminster.—At Tuesday's meeting of the Guardians the House Committee reported favourably upon the question of having the electric light in the house if the cable were brought into the locality. The matter was referred back for further consideration.

West Bromwich.—Sanction has been obtained to the borrowing of £30,000 for land, buildings, and plant for the electricity works, the repayment to be extended over 25 years. The foundation stone of the new electricity works will be laid by the Mayor on the 16th inst.

Ilfracombe.—It is proposed that the electric lighting order be handed over to the firm who could give the best terms. The Council could not at present undertake the electric lighting of the town. The matter has been referred to the General Purposes Committee.

Walsall.—At the last meeting of the council of the Chamber of Commerce it was resolved to support the Dover Chamber in a memorial to Trinity House asking that there should be wireless telegraphic communication between lightships and lighthouses and the shore.

Lymington.—The electric light and power company commenced laying cables on Monday. A part of the shipyard abutting Bath-road has been secured as the generating station, and 9, High-street has been taken as the offices of the company, of which Mr. G. R. Masters is the secretary.

Birstall.—At the last meeting of the District Council a letter was read from the North British Electrical Supply Company intimating their intention to apply to the Board of Trade for powers to supply electrical energy for public or private purposes within the Birstall urban district.

Shoreham.—A communication from the Brighton Corporation asking the Shoreham Council to concur in the Corporation's application to establish a system of telephonic communication and include Shoreham in the area has been referred to a committee of the Urban District Council.

Newburn.—At Wednesday's meeting of the District Council a letter was read from the Tyneside Electric Power Company that, in view of the fact that they had been unable to prove the preamble, and the Bill had been thrown out, they gave notice of their intention to apply for a provisional order.

Aston.—The incorporation question formed the chief subject of discussion at the last meeting of the District Council. It was said they had an electric lighting and tramways schemes before them, and if those could be properly matured 5d. or 6d. in the pound would be put in the pockets of the ratepayers.

Tamworth.—The Town Council recently decided not to support the application of Messrs. Handley and Shanks for a provisional order to generate and supply electricity for light and power within the borough. The promoters, however, intend taking the necessary steps to secure a provisional order without the support of the Council.

Hull.—At a recent meeting of the Corporation Electric Lighting Committee a communication was read from the Hull Chamber of Trade asking the committee to reduce the price of the electric current for motive power. It was decided to leave the matter with a sub-committee for their report. Various applications for the supply of current were agreed to.

Salford.—A motion is to come before the Town Council to the effect that the proceedings of June 20 appointing certain members on the Electric Lighting Committee be rescinded, and that the Selection Committee be instructed to submit in their stead the names of three members of the Council who were not members of the old Electric Lighting Committee.

Heswall.—The Heswall Gas and Lighting Company, Limited, intend to apply for a provisional order during the ensuing session empowering them to construct electric lighting works at Heswall, and to generate, accumulate, and distribute supply of electricity to enable the company to light the parishes of Heswall-cum-Oldfield, Barnston, Gayton, and Pensly.

Electrical Power Storage Co.—From the report of the Electrical Power Storage Company we gather that the orders for E.P.S. batteries are increasing for tramways and power stations. The profit for the year amounted to £5 309 and the directors, after carrying £1,243 to reserve and contingent funds, recommend a dividend of 5 per cent. on the ordinary shares.

Digitized by Google

Bexhill.—The Urban District Council have decided to apply for sanction to borrow £7,772 for additional machinery, extension of mains, lamp-posts, fittings, etc. It was pointed out that Mr. Preece had made allowance for 7,000 lights, and if all these were taken up the engines would be running at full pressure, and should a breakdown occur one engine could not do the work.

Hereford.—At the meeting of the Town Council on Tuesday the Electric Lighting Committee reported that the estimated expenditure in respect to the supply of the electric light during the current year was only £532 in excess of the estimated income, As the expenditure included a repayment of £800 on account of capital, the working for the first year showed a profit of £268.

Egremont.—Messrs. Baker, Lees, and Co., London, have informed the Urban District Council that the Bill to confirm the provisional order had passed through committee of the House of Lords, and was afterwards reported to the House without amendment. The Bill had been read a third time, and now only awaited the Royal assent, which it would receive at the next commission.

Colchester.—On Wednesday a report was adopted in which the Electric Lighting Committee stated, with regard to the appointment of an electrical engineer to take charge after Nov. 30 next, that they had no hesitation at all in recommending the Council to offer the appointment to the present electrical engineer, Mr. Sillar, who had the reputation of being an economical station manager).

Increase in Prices.—We notice that the Electrical Power Storage Company, Limited, have informed their customers that from the 2nd inst. all prices in their catalogue will be increased 5 per cent. on account of the continued advance in the prices of raw materials, especially lead, during the past few months. We understand that this increase also applies to all outstanding estimates.

Bradford.—At the last meeting of the Electricity Committee of the Corporation, plans for the proposed extension of the existing generating station at Valley-road were approved. The committee also resolved to apply for sanction to borrow a further sum of £140,000 for the erection of a new generating station at Valley-road, for additions to existing stations, and for further machinery and plant.

Newark.—The town clerk has been instructed to enquire as to the cost of obtaining a license from the Postmaster-General for providing a system of telephonic communication in the borough. The provisional order authorising the Council to supply electricity has been passed and confirmed. Mr. Vesey Brown is to be consulted with the view to preparing a scheme for carrying out the provisional order.

Larne.—With regard to the electric lighting tender referred to in our last issue, and which was referred to a committee, the latter on Tuesday reported that they did not see their way to take it upon themselves to recommend this large expenditure, believing that it was a matter rather for the consideration of a committee of the whole Council. After some discussion it was agreed to consider the question at a special meeting.

Provisional Orders.—Bills to confirm the Brecon and the Llandilo provisional orders made by the Board of Trade under the Electric Lighting Acts, 1882 and 1888, came on Monday before the examiners of the House of Commons for proof of compliance with the further Standing Orders, they having already been passed by the House of Lords. There was no opposition at this stage, and the Bills were ordered to be reported for second reading.

New Issues.—A company has been registered by Messrs. Jordan and Sons, Limited, of 120, Chancery-lane, London, under the title of the Anti-Collision Alarm Telegraph Company, Limited, with a capital of £1,500, divided into 1,500 shares of £1 each, to carry on business as denoted by its name.—Rosling, Appleby, and Fynn, Limited, announce an issue at par of £15,000 first mortgage 4½ per cent. debenture bonds, and £15,000 cumulative 6 per cent. preference shares.

Barking.—At a meeting of the Urban District Council, a report on the street-lighting was received from the consulting engineer stating that he had allowed for cables large enough to supply two 16-c.p. lamps in each post if they wished them at any future date. The cost of doing this and the extra switches was £2,700. The interest and sinking fund would be £148. 10s., but they would only require one lamplighter instead of three, which would mean a saving of £169.

Filey.—At the last meeting of the Urban District Council a letter was read from the Northern Counties Electricity Supply Company, stating that it was the intention of the company to apply in the next session of Parliament for a provisional order for electric lighting in the Council's area, and asking the Council to appoint a deputation to meet representatives of the company to discuss the proposals. The Council decided not to grant the interview, and to have nothing to do with the matter.

Eastbourne.—The resolution passed at the meeting of the Council on March 5, 1900, authorising application to the Local Government Board for power to borrow the sum of £800 for extensions of electric light mains has been rescinded, and in lieu thereof application is to be made for power to borrow the sum of £2,000 for extensions of electric light mains, the purchase of transformers, meters, and electrical instruments. Gildredge-road has been added to the roads which it is proposed to light by means of arc lamps.

Partick.—At a special sitting of Partick Dean of Guild Court on the 2nd inst., the town clerk appeared in support of a petition by the Commissioners of the burgh for permission to erect a dust and refuse destructor and electric lighting station, with offices, on a piece of vacant ground situated between Partick West Station and Clyde-street. It was ultimately decided to postpone the application till Monday next, when parties will be heard. The estimated cost, including the laying of the street cables for the electric light, is £60,000.

Personal.—Mr. Arthur Ellis, M.I.E.E., at present electrical engineer and tramway manager for the Corporation of Bolton, Lancashire, has been appointed electrical engineer to the Corporation of Cardiff.—Mr. A. H. Howard, who has been for some time manager to W. T. Glover and Co., Limited, has been elected to a seat on the board of directors.—The Brush Electrical Engineering Company have appointed Mr. Edward A. Leeson to the position of works manager at the Falcon Works, Loughborough. His predecessor was Mr. C. E. Hodgkin.

Croydon.—Application is to be made for a loan of £3 360, the cost involved in laying cables for the extension of arc lighting on the whole of the new tramway route. The salary of Mr. T. H. Minshall, borough electrical engineer, is to be increased by £50 per annum, with annual increments of £25 to a maximum of £600, the increase to date from April 1 last. The salary also of Mr. W. Jensen, the assistant electrical engineer, will be increased from the same date by £25, with an annual rise of £25 to a maximum of £275 The salaries of 13 other members of the staff have been raised.

Wedding.—On Wednesday last at the parish church, Knaresborough, the wedding took place between Miss Marguerite Emily Simpson, only daughter of Mr. G. E. Simpson, Parliament-street, York, and Woodville, Knaresborough, and Mr. Charles Midgley, son of Superintendent Midgley, of Dewsbury. After the ceremony a reception was held at Woodville. Nearly 90 employés from the Parliament-street works, York, came in three saloon carriages from York, and were entertained to tea in the town hall, Knaresborough, by Mr. Simpson. Our best wishes accompany the young couple.

London Gazette.—The reconstruction of the Premier Electric Lamp Syndicate, Limited, has been agreed to.—The first meeting in the estate of W. J. S. Green, 45, Birchfield-road, Aston, will be held on July 13, at 11 a.m., at 174, Corporation-street, Birmingham, and the public examination at the County Court, Birmingham, on July 30 at 2 p.m. An adjudication order has also been made out against the above.—Mr. George F. Clarke, 71, Cross-lane, Earlestown, Lancs., incorporated accountant, has been appointed trustee in the estate of G. H. Bentley, 63, Cross-lane, Earlestown, Lancs.

Appointments Vacant.—The Salford Electric Light Committee require an engineer to the electrical undertaking of the Corporation.—The Swansea Corporation require the services of a resident electrical engineer to take charge, under the superintendence and direction of the consulting engineers, of the erection of electric and steam machinery in their electric generating station at Swansea, and of the laying of electric mains in the streets of the borough.—The Wimbledon Urban District Council invite applications for the position of a temporary draughtsman for the extension of the Council's electricity works.—The British North Borneo Company invite applications for the post of superintendent of telegraphs. Full particulars appear in our advertisement columns.

Cardiff.—On Thursday last week Mr. Shepherd, the provincial manager, and Mr. Bell, the district manager, of the National Telephone Company, waited upon the Cardiff Public Works Committee with reference to the subject of placing the telephone wires underground. Mr. Shepherd stated that the overhead wires were so constructed that in some cases it was absolutely impossible to make the connections. They were prepared to pay a wayleave of 2s. per subscriber per annum (there are about 1,200 subscribers). The work of tearing up the street would be done by the Corporation's men and charged to the company. After some discussion the representatives of the company agreed to put their terms in writing, and forward them to the committee in time for their next meeting.

Presentation.—At the Leith Corporation electricity works on Monday, the 2nd inst., Mr. Bryson, the burgh electrical engineer, was presented by his staff with a handsome oak study chair, with silver name-plate attached, on the occasion of his leaving to take up consulting work. The presentation was made by the oldest employé, who wished Mr. Bryson every success, and hoped that he would be long spared to carry on his work—a wish which was heartily endorsed by those present. Mr. Bryson, in thanking his staff, referred to the excellent relations which had existed between them. He complimented them on the excellent way in which they had done their work, and said that as his new office at 16, Charlotte-street was so near, he would often look in to see how his "boys" were getting on. A photograph of the staff was also sent to Mrs. Bryson.

Fulham.—The Vestry are advertising that they will shortly be in a position to supply electricity for lighting, power, and heating purposes. They have decided to charge for lighting purposes 5d., and for heating or power purposes 2½d. per Board of Trade unit. No rent will be charged for the use of meters. With regard to the combined electric lighting, dust destructor, and disinfecting works it is proposed to make the following appointments: chief engineer and manager, £400 per annum, rising to £600 in increments of £50 per annum; destructor superintendent, £160 per annum, rising to £240 per annum in increments of £20 per annum; mains superintendent, £160 per annum, rising to £240 per annum in increments of £20 per annum; chief clerk, £160 per annum, rising to £240 per annum in increments of £20 per annum; three engineers in charge of shifts, £2. 5s. per week, rising to £3. 5s per week in increments of 5s. per week per annum.

Digitized by Google

Devonport.—Colonel C. H. Luard, R.E., has held an enquiry into an application by the Corporation for sanction to borrow £69 727 for electric lighting. The Town Clerk (Mr. A. B. Pilling) stated that it was proposed to locate the electricity station at Newport Quay, Stonehouse, which the Corporation had agreed to purchase for £15,000. Mr. C. Furness, electrical engineer, said three engines and dynamos capable of developing 1,500 h.p. would be laid down. One would be used for electric lighting, another for supplying current for electric traction, and the third held in reserve for either purpose. It was proposed to light the borough with 41 arc lights until midnight, and after that hour with 82 incandescent lamps. Altogether the plant, besides supplying the tramways with electric power, would be of sufficient capacity to light 10,000 8 c.p. lamps.

Hammersmith.—At a meeting of the Vestry on Wednesday the following report of the Electricity and Lighting Committee, which had been standing over from last meeting, was adopted: "The committee have thoroughly gone into the whole question of extensions of mains, and recommend that the streets mentioned in the report be scheduled, and the work carried out at a total estimated cost of £8,877, and that it be referred to them to execute the work from time to time as the demand may arise. In order to meet the cost of these extensions, the necessary transformers for the increasing demand, the connection to the new consumers, and the cost of the extensions of mains already sanctioned by the Vestry and carried out, the Vestry will obtain a loan from the London County Council or otherwise for a sum of £15,500, made up as follows: mains, £8,877. 9s. 1d.; transformers (300 kw.), £1,284; work sanctioned and carried out, £2,550; services, £2,500; contingencies, £288. 10s. 11d.

Obituary.—With much regret we have to record the death of Mr. Montagu Charles Dent, A.M.I.E.E. (of Messrs. Wallis-Jones and Dent, 36, Great George street, Westminster), on June 28, 1900, after a very short illness, subsequent to an internal operation. Mr. Dent received his education from 1885 to 1889 at Eton, and at King's College, London, from 1890 to 1891. He served his time with Messrs. Robey and Co., Lincoln, from 1892 to 1894, and also at the works of the Brush Electrical Engineering Company, Limited, Loughborough, Leicestershire, from 1894 to 1896. During 1896 and part of 1897 he was employed on installation work at Arundel Castle, on central-station work at the Wandsworth electric light station, and in the erection of the exhibition plant at the Earl's Court Exhibition. On Oct. 1, 1898, he joined Mr. Reginald J. Wallis-Jones in partnership as consulting engineers at 36, Great George-street, Westminster, and carried out several important installations of electric light and power plants.

Stock Exchange.—The Stock Exchange Committee have appointed July 11 as a special settling day for Alliance Electrical Company's 70,000 5 per cent. cumulative preference shares of £1 each, fully paid, Nos. 1 to 70,000, and Edison and Swan United Electric Light Company's fully and partly paid provisional certificates for £100,000 5 per cent. second debenture stock. The committee have also ordered to be quoted in the official list Alliance Electrical Company's 70,000 5 per cent. cumulative preference shares of £1 each, fully paid, Nos. 1 to 70 000. Applications have been made for a special settling day in and to grant a quotation to St. James's and Pall Mall Electric Light Company's £150,000 3½ per cent. debenture stock, and the Westminster Electric Supply Corporation's further issue of 30,100 ordinary shares of £5 each. The committee have been asked to allow to be quoted in the official list the National Telephone Company's £500,000 4 per cent. debenture stock; and a further issue of 100,000 ordinary shares of £5 each, fully paid, Nos. 490 001 to 590,000.

Blackheath and Greenwich District Electric Light Co.—An extraordinary general meeting was held on Tuesday at the Cannon-street Hotel, London, to consider resolutions for increasing the capital to £300,000 by the issue of 150,000 new shares of £1 each, entitled to receive out of the profits a fixed cumulative preferential dividend of 7 per cent. per annum, and authorising the directors to create and issue £120,000 of debenture stock carrying 4½ per cent. per annum interest. Mr. J. A. Willox, M.P., who presided, said when the Company began their own supply in February the number of lamps connected was equivalent to 5,900 8 c.p., while at the present time 10,000 lamps were connected. The total expenditure to date had been £128,000, but there were other charges to be brought in. To meet these liabilities, and to extend their area of supply, for which powers had been obtained, additional capital was required. Mr. H. W. Bowden seconded the motion. A discussion followed, and in the result the Chairman promised that the Board would issue no preference shares, except for the purpose of exchange, without first consulting the shareholders. The resolutions were approved.

Electric Fans.—We have received from the Edison and Swan United Electric Light Company, Limited, leaflet No. 137, which deals with fan motors. The "Paragon" fan motor which is listed is for use with continuous current, and of 1900 pattern. It is suitable for use in hotels, ship saloons, smokerooms, etc., and is made in three types—hanging from ceiling, fixing on wall, and standing on desk or table. As usual, the parts are interchangeable, and the armatures can be easily removed. Illustrations of the various types of "Paragon" motor are given, and telegraphic code words to save expense when ordering.—The British Thomson-Houston Company, Limited, have also sent us a list of 1900 fan motors which they are just bringing out. These motors also are made to be used for ceiling, wall, and ordinary positions. These motors are designed with special brush-holders having pressure arms so hinged and held that the pressure on the commutator is constant during the life of the brush, and the brushes wear evenly and cannot turn a sharp edge to the commutator. There are also new electrical features in these motors, the field coils being secured to a magnet frame composed of pure soft-iron laminations. The armature core is also of pure soft iron. Other particulars and illustrations of the motors are to be found in the pamphlet.

Catalogues.—We have received from Messrs. John Fowler and Co., Limited, of Leeds, a copy of their new catalogue of electrical machinery and apparatus. This firm, though principally noted for heavy machinery, has yet a large electrical department. Thus in the catalogue we find listed transformers of the Lowrie-Hall type. The price of these transformers range from £8. 10s. to £137, they being made for frequencies of either 85 or 50 cycles. Terminal covers, underground transformer boxes, transformer switches, and fuses are catalogued. One of these fuses (Hall and Fuller's patent) consists of a fuse wire in an asbestos sheathing, so that an arc cannot be maintained. Surface and junction boxes, the Lowrie-Hall synchronising base, resistances, boosters, and, finally, larger machinery, such as motors, dynamos, and alternators, appear in the catalogue. The list gives descriptions of the various pieces of machinery, and is well illustrated throughout.—We have also received from the Fairbanks Company, of the U.S.A., a booklet which at first sight appears to be a catalogue of tall buildings. On further investigation, however, one finds that it is in these large buildings, which, by the way, are in New York City, that the Fairbanks valves for heating apparatus have been installed. A description of the valves follows the illustrations. We are informed that the Fairbanks Company will be pleased to forward a copy of this book, post free, to any reader sending his name and address to the London office, 16, Great Eastern street, E.C.

Parliament.—The London United Tramways Bill has passed the second reading in the House of Lords. The Dublin and St. Marylebone Lighting Bills have failed to pass the House of Commons. During the past week it was announced before the Select Committee of the House of Lords, which had previously refused to sanction a double tramway or the use of electricity over the level crossing on the North-Eastern Railway in Hedon-road, Hull, that there was the greatest hope an agreement had been or would be come to between the Corporation and the railway company which would enable the tramway to be carried under the railway, by the road being lowered to a certain extent and the railway line raised a little, so as to allow of a workable gradient. The Select Committee of the House of Commons appointed to consider several Bills seeking the sanction of Parliament to the supply of electrical energy in bulk last week, decided that, in the cases of Durham, Lancashire, and South Wales, the preambles had been proved, but that in the Tyneside case it had not been proved. The committee proceeded to go through the clauses of the Bills. At the House of Lords the various local authorities affected by the South Lancashire Tramways Bill met in Lord Morley's room to consider certain objections taken by his lordship's counsel to the clauses put in by the House of Commons Committee to satisfy opponents and accepted by the promoters. After considering the views put forward by the local authorities, Lord Morley agreed to reinstate the clauses, so that the Bill as it now stands is exactly the Bill as it issued from the House of Commons' Committee, and the Bill in the House of Lords will now be practically unopposed. The Batley Corporation Tramways and the Camborne and Redruth Tramways Bills have passed the committee of the House of Lords. Mr. J. W. Lowther's committee have passed the Bill conferring further powers on the Newcastle-upon-Tyne electric supply of electrical energy. Reading Tramways Bill has passed through the Lords. Mr. W. H. Holland's committee passed the Bill promoted by the London County Council asking for powers to equip electrically and operate the Westminster to Tooting tramway and the Blackfriars to Kennington line, to erect a generating station at Camberwell, with sub-stations, and to construct 11 junction lines and extensions in connection with the Council's tramways on the northern side of the Thames, inclusive of all the new tramways asked for. The applications of the local authorities of Lambeth and Wandsworth for a veto on the use of the surface-contact system of electric traction, and in regard to other matters, were refused. The Bill confirming the provisional order obtained by the Weston-super Mare and District Electric Supply Company, Limited, from the Board of Trade, authorising them to construct tramways to be worked by electricity within the urban district of Weston-super Mare has been passed, subject to the insertion of a clause preserving the rights which the Commercial Cable Company may possess in regard to the uninterrupted user or enjoyment of their submarine telegraph cable running to Weston. In the House of Lords the Manchester Corporation Tramways Bill has been read a third time.

Hanley.—A special sub-committee recently appointed to make investigations as to reasons for the electric lighting accounts for 1899 showing a deficiency on the year's working after paying interest and sinking fund charges, reported to the Council last week that they were of opinion that the deficiency in the revenue account was to be attributed to the following causes: (1) too early reduction in the price of current before a reserve fund had been formed; (2) increased cost of fuel, wages, and materials; (3) abnormal repairs to generating plant; (4) increased charges to sinking fund and interest on further capital. The special committee recommended that the Council be recommended to increase the present prices for the supply of electricity of 5d. and 2½d. to 6d. and 3d. per unit from July 1 next, less discount as before. The General Committee recommended that the charge for the supply of electrical energy to places of worship be increased from 4d. to 4½d. per unit, and for heating and power supplied through

Digitized by Google

separate meter from 2½d. to 3d. per unit up to four hours' consumption per day and 1d. per unit afterwards. The minutes were adopted.

Brighouse.—On Saturday week the Mayor (Councillor J. W. Clay) officially opened the sewage outfall works at Cooper Bridge. The works are lighted by electricity, outside by means of arc lamps suspended from elegant pillars and brackets attached to the buildings, and the interior of the works, committee-rooms, and caretaker's house are effectively lighted by incandescent lamps. The wires connecting the arc lamps are laid in iron pipes in the ground. Electric current is generated by a "Churton" dynamo of the standard No. C 12 type, and provision is made by a storage battery for lighting part of the installation while the machinery is not running. The switchboard and other apparatus for controlling the installation, as well as the dynamo, were constructed at Mr. T. Harding Churton's works in Great Wilson-street, Leeds, by whom also the installation has been carried out. The "Ark" lamps have been supplied by Messrs. Johnson and Phillips, and an accumulator of the Chloride type is used in connection with the incandescent lighting of the works, manager's house, and committee-rooms when the dynamo is not running. The whole of the works have been carried out under the direction of the engineer, Mr. Alfred M. Fowler.

Worthing.—At Tuesday's meeting of the Town Council the Electric Lighting Committee reported that they had reconsidered the system of lighting so far as it related to the several streets in which it was proposed to have incandescent lamps of 50 c.p., or their equivalent in cost of arc lamps of 1,000 c.p. The committee also decided to recommend that the streets referred to in Mr. Monkhouse's report be lighted with 40 arc lamps of 1,000 c.p. each (in lieu of the 76 incandescent lamps of 50 c.p. as previously proposed), in accordance with the engineer's report. The Council were recommended, as advised by the consulting engineer, to adopt the "Edinburgh" design for arc-lamp posts as in use in London; and Messrs. Burstall and Monkhouse were authorised to have the various specifications, forms of tender, etc., printed in London as suggested by them, and to advertise for tenders. The action taken by the consulting engineers and the borough surveyor in obtaining 150 yards of conduit casing for putting down in Chapel-road, between Richmond road and Stoke Abbott road, in which new paving is about to be laid, and which will obviate the subsequent lifting of the pavement, was approved and confirmed. These proceedings were agreed to.

London County Council.—At the meeting of the Council on Tuesday it was agreed to lend the Poplar District Board £20,000 for electric lighting purposes; the Strand District Board £1,500 for the purchase of motor-vans; the Battersea Vestry £5,147 for street-lighting purposes; and the Islington Vestry £6,606 for electric lighting purposes. Sanction was given to the Postmaster-General (*a*) to the placing of steel troughing to carry Post Office cables, for which there was not room in the Queen Victoria-street subway, at three places over the subway, and for this purpose to reduce the headway of the subway about 3in. for a distance of between 13ft. and 14ft. near the Post Office Savings Bank, and by rather more at the junction of the north and south subways in the street, while at the third place, near Blackfriars Bridge, it was not contemplated that the subway itself should be interfered with; and (*b*) to the placing of cables in the subways in Northumberland-avenue, Charing Cross-road, and Shaftesbury-avenue. At a subsequent special meeting the proposals of the Highways Committee for serving notices on the London, Deptford, and Greenwich Tramways Company and the South London Tramways Company for the purchase of their undertakings were carried without discussion.

Aberdeen.—A report from Mr. J. A. Bell, Corporation electrical engineer, on the system of charging for electrical energy for lighting and power, came before the Town Council on the 2nd inst. The present scale of charges in Aberdeen for lighting is 6d. per Board of Trade unit for all energy supplied till the meter registers the number of units that would be consumed for one hour per day per half-year by the maximum number of lamps switched on at one time during that half-year. All subsequent units are charged for at 3d. per Board of Trade unit. For power the rates are based on the same principle, the rates being, however, 3d. and 1d. per Board of Trade unit respectively. For display purposes consumers are allowed, by resolution of the Council, to have their indicators disconnected so that the half year's bill is not affected by such displays further than by the increased number of units chargeable at the lower price. Mr. Bell considers the adoption of the maximum demand indicator system has tended largely to the present flourishing condition of the undertaking. He finds that 62 per cent. of the consumers benefit by the rebate system during the year, and states: "Two essential elements of cheap supply are generation on a large scale and a good load factor, and Aberdeen is still poor in the latter respect. In 1899 the generated units in Aberdeen amounted to 655,479, of which probably 600,925 were sold to consumers." An interesting table of charges and other information is also issued, giving details from 57 towns throughout England and Scotland as to electric lighting. It was resolved to defer consideration of the matter for a fortnight.

Norwich.—The Town Council have prepared an agreement subject to which they will support the application to the Postmaster-General by the Norwich Mutual Telephone Company, Limited, for a license from the Postmaster-General for the establishment of a telephone exchange in the Norwich exchange area. The agreement provides for the supply by the company of a constant and continuous telephonic service at low rates; that no preference is given to any subscriber; that a reduction be made for the cost of telephonic service to subscribers when the company's receipts exceed a specified aggregate amount; that the Corporation, under sanction of the Postmaster General, may purchase the plans compulsorily on Dec. 31, 1916 (in 1911 at fair market value as a going concern, with an additional sum equal to three years' profit in addition; in 1916 on the same terms, but with two years' profits in addition); that, subject to any prior rights of the Postmaster-General, the Corporation be able to purchase at the revocation or determination of the license; that the company does not assign, underlet, or otherwise dispose of the license; that the Corporation be represented in the company by two directors with equal votes to other directors of the company; that wayleaves, poles, tubes, etc., be allowed subject to the direction of the city engineer; that the Corporation may determine the agreement if a telephone exchange for 200 subscribers and with three miles of cable is not laid down in three years, or in the event of failure to perform other conditions of the agreement, or if the company is ordered to be wound up.

New Companies.—The following new companies have been registered: Mangano Electric Process, Limited, with a capital of £50,000 in £1 shares, the objects being to adopt an agreement made between G. Bourgoin and H. H. Lavollay and J. F. Medina and M. Urrulla for the acquisition of the rights of G. E. Bourgoin and H. Lavollay in a certain invention for the epuration and decolouration of sugar juices by mangano electric treatment, and to carry on the businesses of electricians, electrical engineers, producers and suppliers of electricity, etc.—The Electrical Testing Laboratories, Limited, with a capital of £3,000 in £1 shares, the object being to acquire the Westminster Electrical Testing Laboratories, 14, Great Smith-street, S.W., and to own and maintain any laboratories and other places where electrical, chemical, or other machinery or other apparatus can be tested, calibrated, or standardised.—The Electromagnetic Traction Company, Limited, with a capital of £1,500 in £1 shares, the objects being to adopt an agreement with H. Lane and W. Griffiths, and to carry on the business of electricians, electric and mechanical engineers, and any business connected with electro magnetism and electric tramway and light railway traction.—The St. Austell and District Electric Lighting and Power Company, Limited, with a capital of £10,000 in £1 shares (300 founders'), the objects being to adopt an agreement with the United Kingdom Tramway, Light Railway, and Electrical Syndicate, Limited, and to carry on the business of an electric lighting company in all its branches.

Whitechapel.—At a meeting of the District Board of Works on Monday the Electrical Committee recommended: (1) That the approval of the Board be given to the election of Mr. John Harris by the committee as chairman of the Electrical Committee for the ensuing year, he having held the office of chairman during the past year. (2) That the proposal of Mr. Arthur Wright, the electrical engineer of the Board, to extend the supply of electricity in the district for lighting and supply of motive power purposes in the manner suggested by the report of Mr. Wright, dated April 27, 1900, be adopted, and that arrangements be forthwith made to carry out the further work contemplated by such report, at the estimated additional cost of £44,670, and that the necessary steps be taken to obtain a loan of £44,670 (the cost of the additional work contemplated) from the London County Council upon the instalment system at the most favourable rate of interest that can be obtained, such loan to be taken up in such instalments as may be required by the Board. (3) That the sum of £20,500, the balance of the loan of £60,500 originally applied for by this Board from the London County Council, be now borrowed from the London County Council in order to carry out a portion of the work of erecting the electric lighting installation in the district, as contemplated by the report of Mr. Wright, the electrical engineer of the Board, dated Nov. 23, 1898, and such further work as may have been since determined upon; such loan of £20,500 to be upon the instalment system, repayable in 42 years, by equal annual instalments, at the most favourable rate of interest that can be obtained, such interest to be payable quarterly; such loan to be taken up at once, the Board paying the costs of such loan and upon the understanding that if any works require to be renewed during the currency of any part of the loan the cost of such renewal shall be provided for out of a sinking fund for the purpose and shall constitute a maintenance charge, and shall not be made the subject of a fresh loan, no part of the principal to be repaid until the expiration of three years from the date of the loan, and that the seal of the Board be affixed to such mortgage when ready, and that a cheque be drawn in favour of the London County Council for the fees in connection with such mortgage when received. (4) That it be referred to the Electrical Committee, with instructions to enter into negotiations with the Guardians of Whitechapel, for the purchase, or a grant to the Board, of a lease of a piece of land belonging to the Guardians, upon which there is a railway siding, and that the committee be instructed to report to the Board the terms (if any) upon which the Guardians will be prepared to dispose of such property to the Board. This was agreed to without discussion.

COMPANIES' MEETINGS AND REPORTS.

BASTIAN METER.

The third ordinary general meeting of this Company was held on Thursday at the offices, Kentish Town, under the presidency of **Mr. C. Orme Bastian**, who, in moving the adoption of the report and accounts, said that the results of the past year could be summed up in two words—viz., "Rapid progress." They had

Digitized by Google

converted a loss of £2,000 shown last year into a profit of nearly £400 this year. During the past three weeks the orders for meters were larger than for the whole of the first six months of the year. They were glad to be able to pay the preference dividend in full, and he believed that the ordinary shareholders would soon receive ample reward for their patience.

Mr. Umberto Ciantar seconded the adoption of the report, which was unanimously agreed to.

THOMAS PARKER, LIMITED.

The annual meeting of Thomas Parker, Limited, electrical engineers and contractors, Wolverhampton, was held at the works, Wednesfield-road, last Friday, Mr. C. T. Mander (chairman of the directors) presiding.

The directors' report, published in our last issue, was adopted, as was also a formal resolution declaring the 10 per cent. dividend.

On the motion of **Mr. J. E. Underhill**, seconded by **Mr. W. Armistead**, Mr. C. T. Mander was re-elected a director, and Messrs. Allen Edwards and Smith were reappointed auditors to the Company.

The meeting lasted 8 minutes and 43 seconds.

ELECTRIC CONSTRUCTION.

Directors: Sir Daniel Cooper, Bart., G.C.M.G., chairman; James William Barclay, deputy chairman; Philip Edward Beachcroft; John Irving Courtenay; Sir Henry C. Mance, C.I.E.; Sir James Pender, Bart., M.P. Manager: A. B. Blackburn, M.I.C.E. Secretary: James Gray.

Report of the directors to be submitted to the shareholders at the seventh annual general meeting of the Electric Construction Company, Limited, to be held on Thursday, July 12, 1900, at Winchester House, Old Broad-street, E.C., at 12 noon:

The profit of the year ending May 31 last, including the balance of £1,441 6s. 2d. brought forward, is £21,729. 1s. 9d., which your directors recommend be appropriated as follows—viz.: in providing a dividend of 7 per cent. on the preference shares (to be paid on July 31 next) £3,500; and a dividend of 6 per cent. on the ordinary shares (one-half to be paid on July 31 next and one half on Jan. 31, 1901), £13,452; leaving a surplus of £4,777. 1s. 9d. to be carried to next year's accounts. The buildings and plant have been thoroughly maintained, and £5,000, as usual, has been credited to depreciation account, which now amounts to £33,000. The buildings of the extensions, referred to in last year's report, have been finished, and the shops are now being equipped with the latest labour-saving tools and appliances, capable of turning out economically and with dispatch the largest electrical machinery that may be required. Among the more important works of last year may be mentioned the power-house and line equipment with British machinery and appliances throughout of the extensions of the City and South London Electric Railway. The works are well supplied with orders at remunerative prices, the relations with all classes of employés are thoroughly harmonious, and the directors have had much pleasure in awarding the usual bonus in recognition of good service. It has been considered expedient to foreclose the mortgage on the Madras electric tramways and to acquire the undertaking, but it is not intended that this should be a permanent investment. Meanwhile the working of the tramway yields a moderate return on the cost, and the traffic is developing satisfactorily. The compensation paid under the Workmen's Compensation (1897) Act is for the year less than £20, but £150 of last year's profit has been credited to the fund to meet such claims. The directors who retire by rotation at the general meeting, and who are eligible for re-election, are Sir Daniel Cooper and Sir James Pender. The auditors, Messrs. James Meston and Co., offer themselves for re-election.

WEST AFRICAN TELEGRAPH.

The ordinary general meeting of this Company was held on Friday at Winchester House.

The Marquis of Tweeddale, who presided, moved the adoption of the report, which appeared in our last issue.

The report was adopted, and a resolution afterwards carried authorising the directors to carry out the necessary arrangements for the establishment of a staff pension fund and superannuation fund, or for joining such funds already established by the Associated Telegraph Companies as they might consider desirable.

EDMUNDSON'S ELECTRICITY.

Directors: John R. Wigham, J.P. (chairman); W. R. Davies; Joshua W. Edmundson; Walter B. Hopkins, M.I.C.E.; Francis E. Gripper, M.I.E.E. (managing director).

Report of the directors, and abstract of accounts, for the year ended March 31, 1900, to be presented to the shareholders at the third annual meeting to be held at the offices of the Corporation to-day (Friday), at 3 p.m.:

Including the sum of £2,572. 5s. brought forward from last year, the net profit, after payment of debenture interest, amounts to £19,832. 6s. 9d. The directors recommend that £5,000 be written off goodwill, and that a dividend of 6 per cent. be paid upon the ordinary and deferred shares for the year ended March 31, 1900, amounting to £10,674. 4s. 2d., leaving a sum of £4,152. 2s. 7d. to be carried forward to the next account. The electric lighting stations at Folkestone, Winchester, Woolwich, Bromley (Kent), High Wycombe, Salisbury, Ventnor, Chislehurst, and Newmarket, all of which were completed a year ago, have been working satisfactorily, and dividends have been paid to the shareholders of the five first-mentioned companies as the result of the first year's working. These results, obtained at so early a stage, must be looked upon as most encouraging, and confirm the belief of the directors that electric lighting in such towns will prove a profitable investment. During the year the stations at Guernsey and Alderley Edge have been completed, and are now working. Details showing the progress of the various stations are given in the accompanying schedule. Work has been commenced for central stations at Montrose, Brechin, Melton Mowbray, Lymington, Sandown, Shanklin, Newport, and Cowes, and parliamentary powers are being obtained, with the consent of the local authorities, for several other towns. A considerable number of private installations for country houses, etc., have been carried out, and this department of the business has been well maintained. Investments in the local companies in which the Corporation is interested have been taken in the balance-sheet at cost price. During the year 9,400 ordinary £5 shares, being the balance of authorised capital, have been issued, and fully paid up. Further capital will be required for the works in progress, and the directors recommend that the nominal capital of the Company be increased to £400,000 by the addition of 40,000 shares of £5 each, and they propose that £100,000 should be issued as 6 per cent.

Digitized by Google

preference shares, reserving the other £100,000 for issue at a future time. One of the directors, Mr. W. R. Davies, retires by rotation, and is eligible for re-election. The auditor, Mr. W. H. May, retires, and offers himself for re-election.

PROVISIONAL PATENTS, 1900.

JUNE 25.

11471. Improvements in electromagnetic brakes. Henry Edmond Walter, 43, Albemarle-street, London.

11486. Improvements in means for preventing sparking in electric switches, commutators, current-conductor contacts, contact breakers, and other electric devices. John Vaughan Sherrin, 77, Chancery-lane, London.

11500. Improvements in arc lamps. Peter H. F. Spies, 18, Southampton-buildings, Chancery-lane, London.

11512. Improvements in telegraphic receiving and translating arrangements. Alexander Muirhead, 323, High Holborn, London.

11519. Improvements in frogs to be used in connection with overhead conductors of electrical tramways and railways. Hugh Godfrey Nicholson, 47, Lincoln's-inn-fields, London.

JUNE 26.

11547. Improvements in fittings for overhead trolley systems of electric tramways. George Hill, 17, St. Ann's-square, Manchester.

11556. Improvements in terminals and supports for Nernst lamp glowers. Marshall Wilfred Hanks, 46, Lincoln's-inn-fields, London. (Complete specification.)

11557. Improvements in ballast resistances and cut-outs for Nernst lamps. Henry Noel Potter, 46, Lincoln's-inn-fields, London. (Complete specification.)

11558. Improvements in systems for lighting by Nernst lamps. Alexander Jay Wurts, 46, Lincoln's-inn-fields, London. (Complete specification.)

11559. Improvements in starting apparatus and cut-outs for Nernst lamps. Alexander John Wurts, Henry Noel Potter, and Marshall Wilfred Hanks, 46, Lincoln's-inn-fields, London. (Complete specification.)

11560. Improvements in terminal connections and supports for Nernst lamps. Alexander Jay Wurts and Marshall Wilfred Hanks, 46, Lincoln's-inn-fields, London. (Complete specification.)

11561. Improvements in Nernst lamps and heaters therefor. Alexander Jay Wurts, Henry Noel Potter, Edward Bennett, and Murray Charles Beebe, 46, Lincoln's-inn-fields, London. (Complete specification.)

11562. Improvements in electric lighting. Peter Cooper Hewitt, 46, Lincoln's-inn-fields, London. (Complete specification.)

11584. Improvements relating to incandescent electric lamps. Casimir Pauthonier, 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, March 30, 1900, being date of application in France.)

11588. Improvements in electric railway systems. George Edward Kent, 18, Buckingham-street, Strand, London.

11597. Improvements in flexible conduits for electrical conductors. Harry Gould Osburn, 18, Buckingham-street, Strand, London. (Complete specification.)

11609. Improvements in means for protecting electrical apparatus from abrupt changes in static potential. Percy Holbrook Thomas, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Nov. 27, 1899, being date of application in United States.)

11610. Improvements in means for protecting electrical apparatus from abrupt changes in static potential. Percy Holbrook Thomas, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Nov. 27, 1899, being date of application in United States.)

11620. Improvements in dynamo-electric machines and electric meters. Henry Francis Joel, sen., 74, Windsor-road, Forest Gate, Essex.

JUNE 27.

11643. Improved switch for lampholders. Frederick Rawlings, 71, Carey-street, Lincoln's-inn, London. (Complete specification.)

11677. Improvements in apparatus relating to the parallel running of alternate-current machinery. Henry Cooke Leake, 322, High Holborn, London.

11692. Improvements in or connected with electrical tramways or railways. Hugh Godfrey Nicholson, 47, Lincoln's-inn-fields, London.

11695. Improvements in alternating-current wattmeters. William Lloyd Wise, 46, Lincoln's-inn-fields, London. (The Union Elektricitäts-Gesellschaft, Germany.)

JUNE 28.

11764. New or improved electric brush-holder. William Ernest Burnand, 119, St. Mary's-road, Sheffield.

11769. Improvements in the construction of electric lamp-pillars. Hardy and Padmore, Limited, and Joseph Southall, The Worcester Foundry, Worcester.

11720. Improvements in or relating to electrical ignition apparatus for exploding the charges in internal-combustion motors and for other similar purposes. Henry Thomas Dawson and Henry Alfred Dawson, 18, Hertford-street, Coventry.

11727. Improvements in or connected with electric switches having intermittent or step-by-step motions. William Kingsland, 33, Chancery-lane, London.

11768. Improvements in electric light brackets or fittings, James Fraser Cornaund, 4, South-street, Finsbury, London.

JUNE 29.

11787. Improvements in electrical starting and regulating switches. Arthur Henry Hickley, 10, St. George's-crescent, Liverpool.

11797. Improvements in regulating devices for alternating electric current circuits. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Elihu Thomson, United States.) (Complete specification.)

11808. Improvements in automatic switches for telegraph and telephone circuits. Luigi Cerebotani and Carl Moradelli, 111, Hatton-garden, London. (Complete specification.)

11812. An improved method of fixing the china or other insulator and also conducting wire in sparking plug for ignition by electricity for gas or other explosive vapour or oil engines. Arthur Marmaduke Hart, 15, Vicarage-park, Plumstead, London.

11819. An instrument for measuring rotary field currents. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Actien-Gesellschaft, Germany.) (Complete specification.)

11824. Improvements in telegraphy and in apparatus connected therewith. Anders Bull 115, Cannon-street, London. (Complete specification.

11825. Improvements relating to electrical installation and distribution. Joseph Frank Smith, 11, Burlington-chambers, New-street, Birmingham.

Digitized by Google

11835. Improvements in electro-pneumatic controlling apparatus. Ernest Rowland Hill, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Jan. 13, 1900, being date of application in United States.)

11840. Improvements in means for preventing sparking in electric switches, commutators, current-conductor contacts, contact breakers, and other electric devices. John Vaughan Sherrin, 77, Chancery-lane, London.

JUNE 30.

11853. Improvements in and relating to flag or banner poles or for use in connection with arc lamps or for other like purposes. James Kershaw Grindred, 2, Old Market-chambers, Yorkshire-street, Rochdale.

11861. Improvements in or connected with secondary batteries. Rankin Kennedy, 33, Chancery-lane, London.

11869. Electric generators for military and other cycles. Henry Vander Weyde, 53, Chancery-lane, London.

11891. Improvements relating to electric traction for tramway and other similar vehicles. Arthur Baisieux, 45, Southampton-buildings, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on July 21.

1899.

7370. Control of electrically-propelled vehicles and trains. Leigh. (Sprague.)

13610. Motor electric meters, parts of which are applicable to motors and dynamos generally. Evershed and Vignoles, Limited, and Evershed.

13617. Electrical measuring instruments. Rimington.

13646. Electrical motive-power apparatus. Hollick.

13846. Manufacture of a composition from rhea fibre applicable for electric insulation and other purposes. Cordner.

14467. Electric traction with overhead conductors. Pease and Burdon.

14563. Electrical alarm apparatus. Eggerding.

14999. Dynamo electric machines. Lamme. (Date applied for under International Convention, April 14, 1899.)

16225. Conduits for laying electrical cables. Nichols and W. T. Henley's Telegraph Works Company, Limited.

16300. Safety fuses for electric circuits. Goslin.

16311. Dry-core electrical cables. Savage and W. T. Henley's Telegraph Works Company, Limited.

16623. Arc lamps. Andrews.

16956. Conduits for electric conductors. Bate.

21470. Automatic charging device for electric meter carriages. Mühlberg.

1900.

1445. Electric transformers. Loring and Clarke. (Date applied for under International Convention, June 24, 1899.)

2964. Manufacture of pipes or conduits for electrical conductors or for conveying liquids or gases or for analogous purposes. Howard.

4169. Electric clock. Golby. (Hansen.)

8476. Induction electric meters. British Thomson-Houston Company, Limited, and Hobart.

9231. Electrolysing apparatus. Haas.

9563. Electric igniters for explosion engines. Bergmann.

NOTES.

Municipal and County Engineers.—The annual dinner of the Incorporated Association of Municipal and County Engineers is to be held on July 19, at 7 p.m., the place of meeting being the Criterion Restaurant, Piccadilly-circus, W.

Another Exhibition.—Yet another electrical exhibition is announced for 1903, the *Elektrotechnische Verein* of Vienna having decided to organise an exhibition from May to October in the above-mentioned year in order to celebrate its twentieth year of existence.

"The Stone Trades' Journal."—The *Stone Trades' Journal*, which has just made its appearance under that title, is by no means a new publication. It has been in existence for nearly 20 years under the name of the *Stonemason*, and as such no doubt it will be known to many of our readers. The first number of the new series, which is published monthly, is very well printed and illustrated, and should find a ready sale.

Indian Electricity.—We noted recently the fact that in certain of the military stations in Northern India the punkah-wallah was to be superseded in the barrack buildings by electric motors. We are glad to notice that not in India alone has the benefit been recognised of having a reliable machine for this absolutely necessary work. Thus we learn that a grant of a quarter of a lakh of rupees has been sanctioned in the current year's budget for providing motors for punkah-pulling and electric light for the public offices in Rangoon.

Wireless Telegraphy.—Experiments were recently made at Brest with wireless telegraphy by Lieutenant Tissot, who has made a special study of this subject. We are not informed what system he employed, but he was enabled to receive very clear messages from the "Masséna," 35 miles at sea. The "Friant," arriving in port, also sent messages, and though sent to the same receiver they were only slightly mixed with those of the "Masséna," and could be easily read. These and other experiments which have been made are with the view of the adoption of aerial telegraphy in the French navy.

Electric Lettuce.—We notice that the New York *Literary Digest* makes some observations on the electrical forcing of plants, and says that the method of horticulture under the influence of electric light has made such advances that the growing of lettuce for salads, in spacious greenhouses, with the aid of electric light, is already carried on as a profitable industrial pursuit near Chicago and elsewhere in the U.S.A. The action of electric currents in stimulating vegetation still remains unsettled, but with what is now known of the influence of micro-organisms upon vegetation, further research on similar lines is thought to be most desirable and very promising.

Uranium Radiations.—At a recent meeting of the Academie des Sciences, M. Henri Becquerel showed that, if on treating a fair quantity of chloride of uranium a very small quantity of barium chloride were put in, the precipitation was richer in active material. The radio activity of sulphate of barium then greatly exceeds that of the commercial uranium chloride. The material in question produced on a photographic plate wrapped in black paper a stronger impression than the uranium. These experiments showed that a portion of the uranium mingled with a very active product which was able to be the actinum, and that, on the other hand, the purified uranium was still active.

Steam v. Electric Trams.—As may be known to some of our readers, the electrical and steam tramways in Sydney (N.S.W.) in some instances run over the same route, and the question of overcrowding on the cars has brought to light the curious fact that the public prefer overcrowding in an electric tram to riding in comfort in a steam one. In Sydney the steam trams are put on as a relief service to the electric trams during the portions of the day when the traffic is heaviest, but although with this relief service a quite sufficient accommodation is provided, the passengers yet insist on getting on to an electric car, in spite of the fact that standing by its side is a steam car which is almost empty.

The Rise in Gas.—The rise in the price of gas has had the result which was only to be expected—namely, to advance the demand for electricity for lighting. This is illustrated in the case of Leyton, where the Urban District Council have decided, on being notified by the West Ham Gas Company that after Midsummer the charge for lighting the public lamps would be increased to £4. 7s. 6d. for each lamp per annum, to at once request the Electric Lighting Committee to convert all gas lamps along the existing lines of electric mains. The Leyton authorities are in our opinion only among the first to take measures of this kind, and we shall probably hear in a few weeks' time that a number of other authorities all over the country have preferred to replace gas with electricity in consequence of the almost general rise in gas prices.

Electrical Street-Sweeping.—We notice that the Budapest Tramway Company had in use during last winter an electric sweeping car for clearing their lines of snow. This apparatus chiefly consisted of an ordinary tramcar frame, under which, both back and front, were placed cylindrical brushes. The brushes were put in motion by a 20-kw. series motor, and were made to revolve rapidly. The total weight of the car was 12 5 tons, and it ran at a speed of from 5 to 7½ miles per hour by the aid of two 20-kw. motors, also worked in series. The cylindrical brushes were of the same width as the track, and had a diameter of 3ft. 7in. They were combined with four other brushes, made to move backwards and forwards, and specially arranged to clear snow and dirt from the metals themselves. The motors for propelling the car and those operating the brushes were quite independent of each other, and the flexible contact cable was in consequence composed of two distinct parts.

Horses and Motorcars.—It is now becoming recognised that it is necessary in order that motorcar and horse traffic may proceed peacefully side by side in our streets, that horses, especially of the better kinds, such as are used in carriages, should be taught not to fear vehicles operated by mechanical power. For this reason, and acting on a suggestion made by Lord Alverstone at a dinner of the Automobile Club, the committee of that club have arranged with the committee of the Ranelagh Club that members of Ranelagh should have an opportunity of sending their horses there on Saturday, July 14, on which day the automobile gymkhana at Ranelagh takes place, in order that they may be trained to encounter motor vehicles without fear, by having an opportunity of examining and becoming familiar with motor vehicles, which will be driven there for the purpose by members of the Automobile Club. In view of the importance of horses being familiarised with motorcars, the Automobile Club would also, we are informed, be glad to make similar arrangements with other clubs.

The British Association.—The annual meeting of the British Association is next year to be held in Glasgow, and a local committee has been appointed to make the necessary arrangements. At a meeting of this local committee last week, it was pointed out by Prof. Young that the jubilee of Glasgow University, the conference of the engineers, and the meeting of the British Association would

Digitized by Google

all take place about the same time. As it was very desirable that these three important meetings should not clash, so that as large an attendance as possible might be secured for each, and that Glasgow might be able to do its very best for all of them, he suggested that a committee should be appointed from the executive to arrange as to the most suitable dates. The suggestion was agreed to, and a representative committee was appointed. It was also agreed to recommend to the British Association as vice-presidents the following gentlemen: Lord Blythswood, Lord Kelvin, Sir John Stirling Maxwell, M.P., the Earl of Glasgow, Lord Provost Chisholm, Mr. J. Parker Smith, M.P., Mr. John Inglis, LL.D., and Mr. Andrew Stewart, LL.D.

Electrically-Cured Disease.—We notice in the *Lancet* a description of an electrical method used for curing lupus. The apparatus used is that secured by Mr. Malcolm Morris from Copenhagen, and has just been put into systematic use in this country. The apparatus for the treatment by a powerful electric light consists of three portions. In the first place, a powerful arc lamp is required, taking from 55 to 75 ampereres; secondly, a means for cooling the light must be provided; and thirdly, it is essential that the operator should be readily able to concentrate the light in a suitable manner. The arc lamp is used, as it is found to be richer in chemical rays and cooler than sunlight. The light is passed through special telescopes with crystal lenses and distilled water to stop the heat rays. Provision is also made for concentrating the light in one spot of about the size of a half-crown. The whole subject, we understand, is to a very large extent experimental, but the progress made is considered very satisfactory. The method is painless, and no anæsthetic is required, and the nerves of the patient are not upset. The drawback of the operation is its tediousness, but the treatment is to be further investigated.

Atomic Magnetism.—The following abstract of a paper by Mr. S. Meyer, contributed to the *Annalen der Physik und Chemie*, appears in the *Journal* of the Chemical Society: "Results previously recorded are supplemented by an investigation of the magnetic susceptibility of copper compounds. The fundamental difference in the magnetic behaviour of cupric and cuprous salts, suggested by Wiedemann, is not borne out by the experiments; cupric and cuprous sulphides are about equally diamagnetic. The molecular volume and molecular magnetism are compared with the sum of the atomic volumes and atomic magnetisms respectively, and it is seen that when contraction takes place in the formation of the compound, the molecular magnetism is increased; when an increase of volume takes place, the diamagnetic character becomes more marked. Hence it is permissible to calculate the atomic magnetism of an element from the molecular magnetism of its compounds only when the molecular volume of the compound is equal to the sum of the atomic volumes. The author points out the advantages of his method of determining magnetic susceptibility over that of du Bois and Liebknecht."

The Original Automobilist.—We gather from the Paris correspondent of the *Daily Telegraph* that the pioneer of automobilism has been unearthed by the French Automobile Club. This gentleman, whose name is Etienne Lenoir, is 98 years of age, and in 1860 took out a patent for a motor worked by the carburation process, and the principle was very similar to that used in gasoline automobiles at the present time. He afterwards made various improvements on his invention, and built a motorcar which worked for a considerable time. Other inventions are also placed to his credit, amongst them being an electric brake, a system of signals, a method of metal galvanising, etc. Like a very large number of other inventors, however, Mr. Lenoir has not profited much by his inventions, and has made neither money nor reputation from them. The Automobile Club of France, however, now intends that recognition, though tardy, shall be paid to the aged inventor's talents, and a deputation of members, headed by the president, will visit Lenoir next week in his suburban residence to present him with a silver-gilt medal in the name of devotees of the new locomotion of which he was the pioneer. We think that a more correct expression would be "one of the pioneers."

Our Volunteers.—We stated in our issue of June 22 that certain of the Electrical Engineers Volunteers in the service contingent in South Africa had been reported as missing. Of these, Corporals A. Charleton, D. F. Colson, and G. Charlton belonged to the Leicester Corporation lighting works, and the father of Mr. Colson has received a cablegram, of which he has kindly forwarded us a copy. This telegram is dated "Capetown, July 4, 1.30 p.m.," and contains but the single word "Safe." There is absolutely no evidence as to the present whereabouts of the senders, and it is supposed that they are yet prisoners of war. The fact that the corps has come into touch with the enemy would intimate that both apparatus and men are proving useful to our army in South Africa. Since we received the above telegram from Mr. Colson we find in the *Times* in the list of prisoners, etc., issued by the War Office on July 10, the information that Sapper G. Charlton, Electrical Engineers, prisoner of war, escaped near Reitz on June 24. He states that the following are prisoners: Lieut. North, Corporal Charleton, Corporal Sellon, Sapper Colson, Sapper Landon, and Sapper Peart, Royal Engineers; Sergeant Hugh, Electrical Engineers, and about 30 sappers.

Swiss Water Power.—The water-power station at Thysy-Hauterine is, we learn, to be opened at the beginning of next year, and will furnish power to various works in the district at from £3. 12s. to £4. 12s. per horse-power per annum, instead of from £6. 8s. to £7. 4s., which is the present rate. This reduced tariff will make it possible for electricity to be used in agricultural undertakings by furnishing the motive power to fixed machines, such as thrashers, straw-cutters, stonebreakers, etc. The installation will be composed as follows: Above the Thuzy Bridge on the River Sarine is a dam to raise the level of the water and bring it in an open canal about 550 yards long. The dam is provided with automatic doors, which open when the water attains a certain height. This arrangement permits a regular flow into the canal. From the open canal the water enters an underground canal about 9,800 yards long, which extends to Monteynan, opposite Hauterine, where the water-power station is being built. The construction of the tunnel is the most important part of this undertaking, and the water which is not used for the turbines will run to waste by an overflow canal. Water under pressure reaches the station by two conduits 160 yards long and about a yard in diameter, and sets in motion the turbines and dynamos which will produce the electrical energy.

The Northampton Institute.—We have received from Mr. R. Mullineux Walmsley, D.Sc., the principal of the Northampton Institute, an announcement of a new departure in the form of day courses in engineering, which is to be introduced this coming session. The courses are intended for students who desire to obtain a good technical training in engineering before being apprenticed in engineering works, or for those already engaged in actual engineering work who are desirous of consolidating and extending their knowledge of the fundamental principles under-

Digitized by Google

lying such work, and the most recent applications in particular directions; and who are desirous of benefiting by the instruction provided, with a view to proceeding later on to the highest technical instruction which can be obtained. The engineering day courses are divided into three departments — viz., mechanical engineering, electrical engineering, and horological engineering. In the electrical engineering department, besides ordinary electrical lighting and power work, special attention is to be paid to electric traction and electro-chemistry. Before being admitted to these classes, as the authorities think it essential that a student should have a sound preliminary education, an examination is to be held, only students passing this being allowed to enter the classes. The examination would appear from the subjects taken to be about equal to that for matriculation. The fee for the day students for any one complete course is to be £15, or £16 if paid in instalments at the beginning of each term.

Steel Rails.—The committee which was appointed in 1896 to enquire into the loss of strength of steel rails after long use on railways, and to see what steps could be taken to prevent accidents arising from this cause, has recently issued its report. The committee, which had Mr. Ritchie as formal president, consisted of the Right Hon. Lord Blythswood (chairman), Sir Benjamin Baker, K.C.M.G., F.R.S, Sir Isaac Lowthian Bell, Bart., F.R.S., Prof. Wyndham Dunstan, F.R.S., Prof. A. B. W. Kennedy, F.R.S., the late Sir F. A. Marindin, R.E., C.M.G., Mr. E. P. Martin, Prof. W. C. Roberts-Austen, C.B., F.R.S., Dr. Thomas Edward Thorpe, F.R.S., Prof. W. Cawthorne Unwin, F.R.S., and Mr. Edward Windsor Richards. The committee do not appear to suggest any very decided remedies, such as the management of the State railways in Austria-Hungary employ. On these railways a rail must be renewed as soon as it has suffered a diminution in height of 6mm. on a total height of 125mm. In Germany no precise limit is fixed, but both in that country and in Austria trial stretches of rails from one cast of steel—the chemical composition and physical qualities of which have been ascertained—are laid down and are carefully observed. The results of the chemical and mechanical experiments with fractured rails which the committee have made suggest generally that the durability of rails depends largely on the structure, but beyond suggesting strength and care they offer no very positive recommendations. As regards chemical composition, they think it undesirable to insist on too high a proportion of carbon, manganese, or silicon in the steel.

Coal Tests by X-Rays.—We notice in *Kühlow's Trade Review* a description of some coal tests carried out with Röntgen rays. The article states that previous experiments having led to the conclusion that the permeability of coal towards the Röntgen rays affords no reliable indication of the ash content of the sample, in that the accompanying slate is relatively transparent under their influence, whereas the presence of a comparatively small quantity of oxides of the heavy metals is sufficient to offer considerable hindrance to the passage of the rays, the matter was subjected to further investigation. A selection of the purest of a number of lumps of coal was made by examination with a Röntgen ray apparatus. These samples were reduced to powder and passed through a fine sieve, the ash content being determined by direct calcination at 1·66 per cent. After this, six kinds of pitstone were powdered and sifted in the same way, their percentage of residue and iron content being also determined. The kinds of stone tried were grey slate which had a residue of 93·14 per cent. and 0·79 per cent. of iron, three kinds of black band having percentage residues varying between 43 and 65 per cent. and iron between 25 and 39 per cent., and two kinds of ferruginous slate having residues of 43 and 44 per cent. and iron 19 and 13 per cent. Mixtures were then made of the coal and stone samples, so that the percentage of ash was in each case alike—viz., 10 per cent. These mixtures, placed in paper boxes, were then exposed to the Röntgen rays for three minutes, the distance between the tube and plate being 9in. In spite of the uniformity of their ash content, the samples showed great difference in regard to their permeability, the hindrance to the passage of the rays being in direct proportion to the amount of iron present. The sample containing the smallest quantity (0·07 per cent.) of iron was almost perfectly transparent, whilst that at the other extreme of the series (5·4 per cent. of iron) gave a fairly dense black print, the others ranging in depth of colour between these limits. As for practical use the total percentage of ash is the sole point in question, the author of the article therefore concludes that, however interesting it may be from a scientific standpoint, the Röntgen ray test for ash determinations is quite valueless commercially.

New York Journalism.—We have had to complain several times of the utter nonsense which is published in the American daily papers under the heading of interviews with Edison and Tesla. It is our belief that a large proportion of these interviews are sheer fiction from beginning to end, and that in other cases the ignorance of the interviewer is responsible for a lot of the statements. The fact remains, however, that both Mr. Edison and Mr. Nikola Tesla are fond of expressing their views in the non-technical Press. This failing is commented on in the New York *Morning Journal* by the well-known writer, Mr. Ambrose Bierce. The following is an extract from this gentleman's statement of the case, and it would be interesting to know if he has been in the past responsible for any of the high-flown interviews which he now condemns. Mr. Bierce says: "In creating the new science of electrology the Author of all things seems, for some reason to us unknown, to have decreed that only fools should attain to proficiency in it. Of Thomas Edison, the Blind Tom of the science, it may be said that he knows more about electricity, and less about everything else, than any man living except Nikola Tesla. Neither of these men ever opens his head to tell us what he knows without diverting attention from the performance to the gigantic sum of what he does not know. Both appear to suffer from an incontinence of words aggravated by an impediment in sense. They always think 'the time has come,' as the walrus said, 'to speak of many things,' and of many things accordingly they do everlastingly and pitilessly speak; but mostly of what they are about to accomplish in the way of turning the world inside out and the universe outside in. A favourite topic with these peaceful civilians is war, which they are always going to 'revolutionise' or 'abolish.' Many of this paper's readers will recall Mr. Edison's leglong utterances on this topic just before the Yanko-Spanko unpleasantness—how his electrified water fired from a garden hose was to paralyse entire legions, his electrified chains flung out of two guns each were to mow them down, his torpedoes travelling on endless trolley lines under water were to make smithereens of battle craft, and the rest of it; all showing with clarity his fitness for the great leather medal of the Society of Friends for distinguished services as one of the horrors of peace. Mr. Edison's conception of what war is like would, if it could be photographed, resemble a combat between a set of ten-pins and a row of beer bottles."

The Motorcar Tour.—The report of the committee of judges on the results of the 1,000-mile trial of motor vehicles, which was carried out between April 23 and

Digitized by Google

May 12, has just been published. The judges state that they have allotted marks under 24 headings, such as price, weight, mechanical efficiency (as shown by hill-climbing trials), accessibility of mechanism, workmanship, regularity of running, etc. Eighty-three vehicles were entered for the trial, but some of these, for various reasons, were not ready at the time of the start. Sixty-five vehicles actually started, and, with few exceptions, all covered the whole or the greater part of the course. The cars were divided into two sections—viz., those entered by manufacturers and agents, and those privately owned. In the first section, seven maintained a speed of 12 miles per hour in England and 10 miles per hour in Scotland over the whole course; in Section 2, five performing the same feat. A very large number of other cars completed the entire trial, but either failed to maintain an average speed up to the legal limit in one or more of the stages, or were unable to supply the official records for the whole journey. The gold medal for the most meritorious vehicle, irrespective of class, the owner having accompanied the vehicle throughout and having driven and steered at least half the distance, is awarded to the 12-h.p. Panhard owned by the Hon. C. S. Rolls, in addition to which 10 silver medals were awarded to other competitors. The report describes in detail the performances of the various cars throughout the trial, and dealing with the causes of the failures which occurred, the judges state that enquiries tend to show that most of these were due, not to defects in the motors or in the transmission gear, but to structural weaknesses in other parts of the carriage. For example, breakage of axles took place in three instances, and the puncture of pneumatic tyres was especially responsible for delays. The judges trust that manufacturers of wheels, springs, axles, and tyres will pay especial attention to the manufacture of parts of suitable material, design, and proportion for use in the construction of motor vehicles. They consider that extremely satisfactory progress has been made, not only in the construction of the vehicles generally, but in the arrangement, accessibility, and workmanship, particularly in this country, of the transmission and other gear of many of them. They also note marked improvement in the carriage-builder's work of several of the cars.

The New South Wales Electrical Association. The annual meeting of this association was held recently at Sydney. Mr. O. W. Brain, acting electrical engineer to the New South Wales Railway Department, was president, and in his address gave some useful information as to the progress of electricity in Australia. Thus, he stated, the most important event last year was the opening of the tramways in George-street, which was the first step towards an entirely electric system of tramways in Sydney. This was being brought about as quickly as the Railway Commissioners could do so. There were then 180 cars working on the electric lines, and the number increased weekly. In Perth (W.A.) also during the past year a system of electric trams had been installed, the plant comprising two generators coupled to Canadian engines, and each having an output of 225 kw. The cars, of which there were 20 now running, were furnished with 25-h.p. motors and the usual American double motor equipments. In Brisbane, Queensland, there were now about 60 cars, and the length of track was 20 miles. The Westinghouse Company had secured the option of purchase of the Adelaide (S.A.) tramways, and there seemed a probability that the entire system would shortly be converted and extended. The same company also propose to electrically equip portions of track at Dunedin (N.Z.), and an English syndicate has a complete electric tramway plant under order for Auckland. The most interesting lighting event of the year in Australian lighting was stated to be the installation of the Parsons steam-turbine plant in the Victoria Commissioners' lighting station at Spencer-street railway station, Melbourne. There are three "turbine-alternators" installed, each consisting of a turbine coupled direct to a bipolar generator, the output of which is 150 kw. at 3,000 revolutions per minute. The supply is 2,000-volt single-phase alternate-current, with a periodicity of 50 cycles per second. The exciter armature is on an extension of the engine shaft. Ferranti rectifiers are provided in the Spencer-street station to meet the arc lighting requirements. The president then went on to speak of the signalling arrangements as used by the New South Wales Railway Commissioners, and stated that the track electrically protected by block, staff, or tablet had increased from 123 miles to 1,170 miles, the length of electric line wires, other than for power and lighting, from 2,000 miles to over 6,000 miles, and the number of telephones from 75 to 1,150, other electrical appliances having increased in similar proportion. The president finally thinks that with electrical tramways and lighting, and the electrical disposal of sewage, electricity seemed destined to play an important part in the improvement of the town.

Reduction by Electrolytic Metals.—The following abstract, which appears in the *Journal* of the Chemical Society, is of a paper by Messrs. A. Binz and A. Hagenbach, which appeared in the *Zeitschrift fuer Elektrochemie*. The abstract reads as follows: "When indigotin is suspended (*a*) in a solution of sodium hydroxide, (*b*) in a solution of zinc oxide in sodium hydroxide, and the two liquids are placed in the cathode compartments of two electrolytic cells with zinc cathodes through which the same current is passed, then the indigotin in solution (*b*) is more rapidly reduced than that in solution (*a*). The deposition of zinc at the cathode would thus appear to exercise a more vigorous reducing action than the evolution of hydrogen. Indigotin is not a very suitable substance, however, since it is insoluble in the liquids used. Subsequent experiments were made with solutions of diamine-pure-blue, Ponceau R, and patent blue N. The influence of the cathode metal was first investigated. The solution was placed in the cathode compartments of two cells which differed only in the nature of the cathode metal, and through which the same current was passed. The colouring matters were dissolved in solutions of potassium hydroxide or of potassium or sodium acetate. The metals used were copper, platinum, zinc, and mercury, and in the case of the latter no amalgam was formed, the alkali metal being redissolved as fast as it separated. Practically no difference was found in the rate of reduction with the different cathodes. By using a concentrated solution of pure potassium hydroxide, an amalgam of potassium is obtained at a mercury cathode which is acted on very slowly by the solution. With a dilute solution of potassium hydroxide, the potassium is dissolved out of the amalgam much more rapidly. By using a concentrated and a dilute solution of potassium hydroxide, it is therefore possible to have evolution of hydrogen in one cell, and formation of amalgam in another. In this way it is shown that, when hydrogen is evolved, the reduction of the colouring matters takes place very much more slowly than when an amalgam is produced. These experiments point to the alkali metal being the real reducing agent, and not the hydrogen liberated by the action of the metal on water. To test this further, zinc is caused to separate at a mercury cathode from a saturated solution of zinc oxide in sodium hydroxide in one cell, and hydrogen to separate from a

Digitized by Google

solution of sodium hydroxide at a copper electrode in the other, both cells containing the same colouring matter. No hydrogen is evolved by the contact of the zinc amalgam with the solution, so that any reduction which which occurs must be due to zinc. As a matter of fact, it is found that the reduction always takes place more rapidly in the cell with the zinc than in that in which the equivalent quantity of hydrogen is liberated. The authors conclude that many cases of supposed reduction by nascent hydrogen are really cases of direct reduction by a metal."

"The Tramway and Railway World."—We have received the July number of the *Tramway and Light Railway World*, which, as would be expected from the part which the proprietors took in promoting the Tramways and Light Railways Exhibition, is a special exhibition number. The issue contains some very interesting and well-illustrated articles, and the printing quite comes up to the special numbers of similar American papers, in which the printing has received special praise. The first article deals with the new works of the English Electric Manufacturing Company, Limited, of Preston. On looking at the views given, which show the interior of the various departments, one hardly needs to look at the printed matter to understand the large size and splendid equipment of these works. The question of economy by the subdivision of power into small units has been carefully considered, and sections of shaft are driven by individual motors of 50 h.p. The shaft of 800ft. is divided into eight sections, any one of which can be driven independently by its own motor. The power-house, at which the electrical energy is produced, is 144ft. long and 120ft. wide, and contains a coal-storage room, boiler-room, engine-room, battery-room, and reservoir. The boiler-room contains three 500-h.p. Lancashire boilers, a Green's economiser, and boiler feed pumps. The engine-room contains two cross-compound Corliss engines direct coupled to 400-h.p. generators. The whole of the buildings of the company are lighted throughout by electricity. Another article of the greatest interest to residents in London at the present time is a description, by Mr. J. Clifton Robinson, of the London United Tramway Company's new overhead system. The article is divided up into three parts — the history, description, and argument of electric traction for tramways—and we regret that the actual description of these new tramways should take so small a place in the article. The illustrations of the overhead work and of the progress of the new buildings are, however, very interesting. "Electric Canal Haulage," "The Power Bills," interviews with various leading municipalists on the "Prospects of Electric Traction in the United Kingdom," "Westinghouse Traction Apparatus in Paris," a description of the opening ceremony of the Tramways Exhibition, etc., make up this very good number of the *Tramway World*.

A National Physical Laboratory.—Mr. Hanbury M.P., on Thursday week duly received the deputation of eminent scientists who wish to obtain a site in Old Deer Park, Richmond, for a new National Physical Laboratory. Amongst the deputation were Lord Lister, Lord Rayleigh, Lord Kelvin, Sir Courtenay Boyle, Sir John Wolfe Barry, Sir M. Foster, M.P., Sir E Carbutt, Sir N. Barnaby, Sir Andrew Noble, and Profs. Rücker, Clifton, Schuster, Fitzgerald, and Elliott. Lord Lister said the Royal Society was deeply interested in the question of the new National Physical Laboratory, and they were supported by all the scientific bodies in the kingdom. Lord Rayleigh, as chairman of the National Physical Laboratory, said they recommended "That the institution should be established by extending the Kew Observatory in the Old Deer Park, Richmond, and that the scheme should include the improvement of the existing buildings at some distance from the present observatory." The Kew Observatory had been doing very valuable work of a similar character to that proposed to be undertaken in the new institution, and this alone suggested the Deer Park as a natural site. There were very few sites that were likely to be at all suitable, as the character of the work to be carried out was of the kind which must be removed from mechanical and electrical disturbances. Electrical disturbance was a new feature, but one that might be made from tramways anywhere. No private site could, therefore, meet the case, because there was no security from other buildings creating mechanical and electrical disturbances. As to the distances at which these disturbances would be felt, it was stated that a scientific committee were advising the Board of Trade on the subject. It was this consideration which greatly limited the choice of sites for the laboratory, and it was recognised by the Greenwich Observatory being placed in the middle of a park; the German institution at Potsdam was in a park, and the International Bureau of Weights and Measures stood in the park of Sèvres. In a public park they had some guarantee that the buildings would be free from electrical and other disturbances. Some comment had been made as to the 15 acres required, but one of the reasons for that large area being taken was that they wanted one of their buildings to be at a considerable distance from the other. It had never been proposed to cover the whole 15 acres with buildings. The actual area proposed to be covered with buildings was only a quarter of an acre, or the sixtieth part of the whole area proposed to be taken. As to whether Kew could be protected from disturbances and if the observatory would not have to be removed, it was stated that the importance of continuity in keeping the observation at Kew made it desirable to have all the new buildings there. As to the buildings proving a nuisance, it was to get away from nuisances that they wished to go there, and absolute quiet was needed for their observations. A great advantage of the Kew site would be its nearness to London. In reply to the deputation, Mr. Hanbury said he hoped they were under no misapprehension whatever as to their strong desire that the scheme for a physical laboratory should be carried out. The money had been promised, and they were anxious to find a site. As to the absolute importance to the country of having a laboratory of that kind there was no doubt whatever. That was not the question raised by the Treasury or by any deputation. The real difficulty had been how far the undertaking would interfere with the amenities of Kew Gardens. They wanted to satisfy both the scientists and the lovers of nature. Undoubtedly there had been some alarm among a certain portion of the public, especially those interested in Kew Gardens and open spaces, that this might to a certain extent interfere with the amenities of Kew. He was bound to say that the impression he had gathered from them that day was to a great extent that alarm was unnecessary. From what Lord Kelvin and others had said he was satisfied that as to noise there need not be any alarm. The most important point that had come out was as to whether, after all, on this site they were secure against electrical disturbance. They ought to wait for the report of the Board of Trade committee to see how far it would meet their requirements. He understood that if there were any extensions of the buildings required it would be only to a small extent, and the public need not fear that the whole of the 15 acres would be built over.

THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

EIGHTH ANNUAL MEETING AT KIEL.

[BY OUR OWN CORRESPONDENT.]

(Continued from page 908, Vol. XXV.)

The second paper, contributed by Herr von Moltke, attempted to define the essential requirements which a system of fire-alarms for towns of medium and large dimensions should be designed to meet. The author expressed these requirements in two sentences: (1) every person in any part of a town should be provided by the system with ready means of communicating at any time with the fire brigade; (2) the apparatus serving to transmit the alarm should be so designed as to practically exclude the possibility of failure, while the transmission of the alarm should be quick, and overlooking or false interpretation of the same at the fire brigade station impossible. Continuing, the author enlarged upon these points. One of the principal advantages of an electrical system of fire-alarms, he pointed out, was that the same might be supervised and kept in order by any intelligent person, no technical knowledge being requisite. Still further simplification of the electrical systems of fire-alarms now in vogue might, however, be anticipated, as all improvements tended that way. But the degree of perfection already attained was such that no town not already in possession of an electrical system of fire-alarms should hesitate longer to adopt the system in the common interest. The danger of serious fires, with all their attendant suffering and inconvenience, would be lessened thereby. The cost of installation incurred by an authority in putting down an electrical system of fire-alarms was so abundantly repaid by the greater security obtained, that persons in authority who neglected or opposed improvement in this direction took upon themselves a grave responsibility. In conclusion, the speaker hoped his words would help to strengthen general confidence in electrical systems of fire-alarms.

Following the above paper, Herr Anhagen, superintendent of the fire brigade at Kiel, gave a detailed description of the network of fire-alarms installed in the town, and of the electrical apparatus employed in connection therewith. The accompanying diagram (Fig. 1) shows the arrangement of the fire-alarm pillars and the method of connection employed between these and the several brigade stations. It would be needless here to enter into further details of the system, beyond mentioning that the aggregate length of the three circuits employed amounts to about 16 miles.

Several papers of a more technical character followed, to which we may refer at greater length later on. An interesting contribution was that by Herr George Dettmar upon the necessity of formulating rules for the determination and quotation of the output, temperature rise, and efficiency of electrical machinery. In concluding his remarks, Herr Dettmar introduced a proposal by the Hanover branch of the Verband that the above question should be submitted to a special commission, a proposition which was duly acted upon.

Business concluded for the day at about 4 p.m., whereupon excursions to various works, etc., of interest in the neighbourhood were undertaken. But before following these, brief reference may be made to an interesting demonstration with the Slaby-Arco modification of Marconi's system of wireless telegraphy by the Allgemeine Elektricitäts-Gesellschaft, with the active support of the marine authorities, on the spot. Great interest was excited by the experiments, which were conducted between the Marine Academy and some of the ships-of-war lying off Kiel. Messages were exchanged with two of the ships, even to Press correspondence being successfully transmitted from sea to shore. It deserves incidental mention that messages have already been transmitted with the system in question over distances up to 37 miles without difficulty.

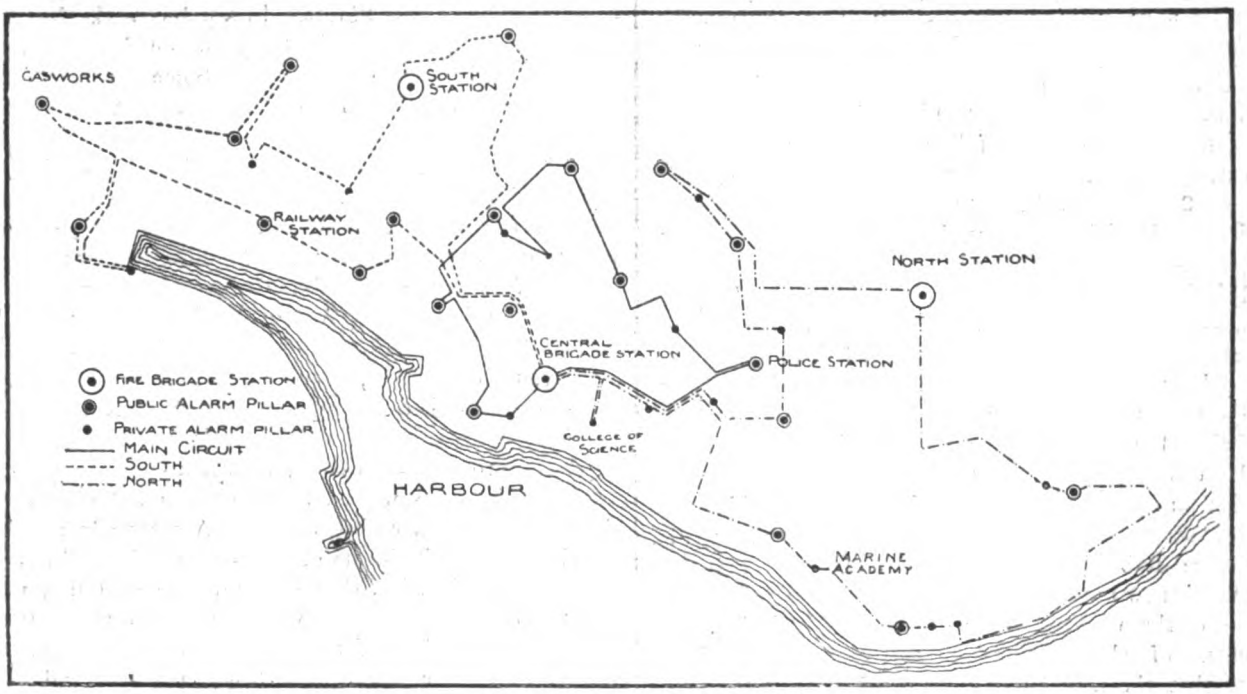

FIG. 1.—Arrangement of Fire Alarms, Kiel.

Considerable interest was also shown in an exhibition arranged to give those present a practical idea of the progress made in electrical matters during the year. An exhibition for this useful purpose has become one of the annual features of the meeting, and its popularity is growing year by year in a rapid manner. The exhibition with which we are at present concerned was larger and at the same time more interesting than its predecessors, a result no doubt largely contributed to by the considerable space devoted to apparatus employed on modern warships or during the construction of the same. Visitors to the exhibition hence obtained a grand opportunity to study both the direct and indirect application of electricity to the appliances of modern sea warfare. Individual reference to the exhibits of note must, however, be left over for the time being, while I deal more fully with the objectives of some of the excursions mentioned above. In doing this I shall not attempt to adhere to the order of the programme, but first of all proceed to the Kaiser Wilhelm Canal, an inspection of the electrical and hydraulic arrangements of which constituted, perhaps, the principal attraction of the day's entertainment. Much has been written about the canal in question, which, as is well known, connects the North Sea with the Baltic, and constitutes one of Germany's most recent and important engineering achievements. An illustration of one of the principal bridges—all of which are noted for their

Digitized by Google

great span—over the canal, with the Imperial yacht "Hohenzollern" passing underneath, appeared with the first instalment of this article. But it is with the electrical arrangements for lighting a canal some 62 miles in length from end to end, so as to enable navigation by night, that I have to deal with more particularly here. The order sounds a big one, and great praise must be accorded to the Helios Elektricitäts Aktien-Gesellschaft, Cologne, for its successful execution. I believe I am right in stating there was no precedent to the work which I am about to describe. Electricity had certainly been previously transmitted to considerable distances for power and lighting purposes, but amongst the many examples of the successful application of electricity at points more or less remote from the generating source, not one involved a tithe of the difficulties which had to be overcome in lighting the Kaiser Wilhelm Canal throughout its length. Not only the lighting of the canal itself, but also the considerable demand for the locks, harbours, buildings, etc., had to be provided for. To meet these several requirements two generating stations have been erected—one in Holtenau and the other in Brunsbüttel—situated respectively at the Kiel and Cuxhaven ends of the canal. In the equipment of these stations great care was taken to provide reliable and economical machinery, while, as an additional safeguard against breakdown, a complete reserve of plant has been installed. The pressure of the current generated is maintained constant by means of automatic regulation, no matter how the load may vary. Each lamp fixed is completely independent of the others, so that the switching out or extinction of a large number of lamps through any cause has no influence upon the working of the remainder.

So much for general particulars; now to proceed to detail. Near the locks situated respectively at Holtenau and Brunsbüttel are erected two pumping stations, which serve to provide the requisite hydraulic pressure for working the lock gates, etc. The boilers in which steam is generated for driving the pumps serve at the same time to supply steam for driving the electrical generators, which are situated at each station in close proximity to the pumping machinery, though in a separate room. The equipment of each generating station comprises two slow-speed steam-engines of the compound tandem horizontal type so much favoured in Germany. These machines run at 85 revolutions per minute, each developing about 200 effective horse-power at that speed. The high and low pressure cylinders have diameters of 16in. and 24½in. respectively, the stroke being 3ft 4in. Centrifugal governors are fitted. At the Holtenau station separate surface condensers are installed, but the machines are arranged so that they may exhaust into the central condenser of the hydraulic department if necessary, or work non-condensing. Mounted between the driving shaft bearings of each engine is an alternate-current generator, having a stationary armature supported from the bed-plate carrying the bearings, and a rotating field system built up on the periphery of the flywheel. The magnet cores, which are bolted to the periphery of this flywheel, are composed of ½mm. iron plate, and number 72. Care has been taken in the design to obtain a magnetic circuit of low resistance. The exciting coils are supported by heavy shoes. The diameter of the magnet wheel being 15ft. 7in., the velocity at which the armature coils are cut by the field lines is therefore 4,000ft. per minute, which gives a frequency of 50. The armature is not only divided through the plane of its axis, so that the upper portion may be lifted off; but, in addition, may also be removed bodily to one side over slide bearings provided for the purpose, thus rendering both the armature and field coils completely accessible. Moreover, the armature coils are so arranged that each may be removed from the side, together with its respective core, upon loosening four screws. The Helios Company have abandoned in this type of machine the ⊥-form of armature coil and core formerly employed. In the newer form (Fig. 2) each core overlaps its winding on the magnet side to such an extent that the complete armature presents an iron surface to the influence of the field excitation, which is broken only by small interstices between the individual cores. The pressure of the current generated at the terminals of the machine amounts to 2,000 volts. The current curve and magnetic and electrical ratios are proportioned to obtain, on the one hand, an economical supply of energy to an installation of arc lamps with 28 volts terminal pressure at the lamps, and, on the other hand, to ensure minimum disturbance through the distortion of phase arising from the long-distance transmission. A four-pole shunt-wound dynamo, with a disc armature, mounted on an extension of the main driving shaft, serves to generate the requisite exciting current for the field-magnet system. The pressure of the exciting current amounts from 120 to 150 volts.

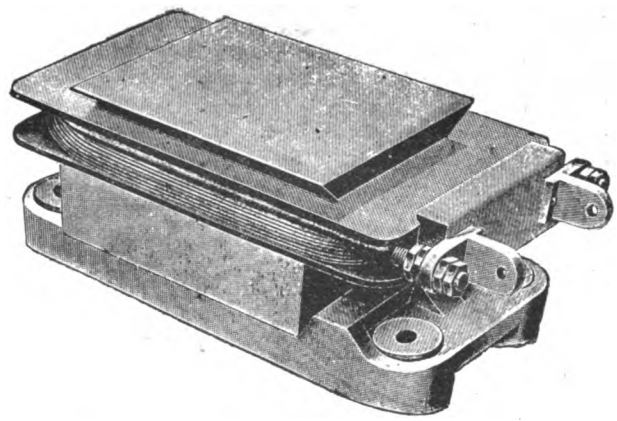

FIG. 2.—Armature Coil, Helios Alternator, Kaiser Wilhelm Canal.

The field of the exciter is automatically regulated by means of a Tesla motor without a commutator or collector ring. At a higher pressure than that of 72 volts transformed in the engine-room, the motor switches resistance into the field circuit of the exciter, or switches resistance out at a lower pressure. A maximum current of one ampere suffices to actuate the regulator. On normal load the steam generators, with a steam pressure equal to 90lb. per square inch in their valve chests, develop 1,000 kw. each on a steam consumption of 2,750lb.—that is to say, 1 kw. for 27·5lb. steam per hour.

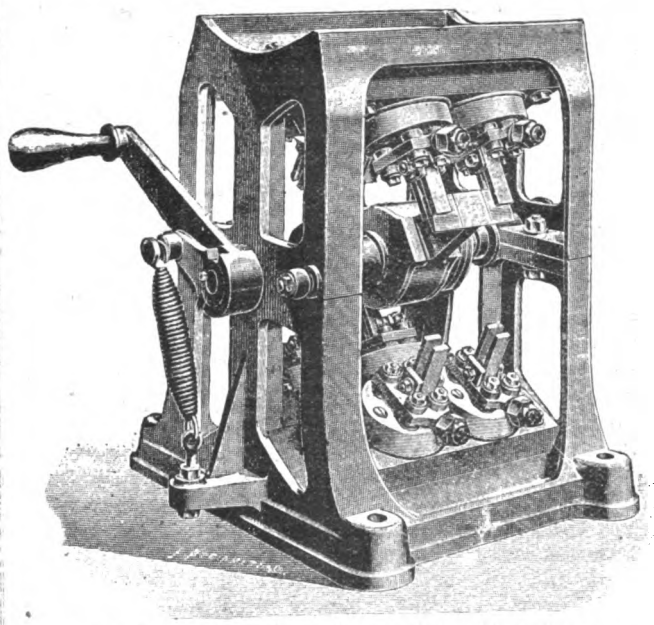

FIG. 3.—High-Tension Switch, Helios type, Kaiser Wilhelm Canal.

One steam set suffices both at the Holtenau station and at Brunsbüttel to take the full load, so that the second machine in each station provides a complete reserve. A small steam dynamo, capable of developing an output of from 9 h.p. to 12 h.p., serves for the day lighting load in Brunsbüttel. This set runs at 150 revolutions per minute, and may also be employed for exciting the alternators if necessary. A day-load generating set has also been installed in Holtenau. The switchboards in both stations are of very handsome appearance, having surroundings of gold coloured bronze in ornamental relief. The

Digitized by Google

high-tension switches, situated behind the boards, are actuated by strong levers (see Fig. 3), from which it will be seen that all the contacts are double-pole. Triple insulation is employed on these switches, one being of porcelain and two of vulcanite. The measuring instruments, mounted upon white marble with vulcanite insulation, record the pressure and current strength of the

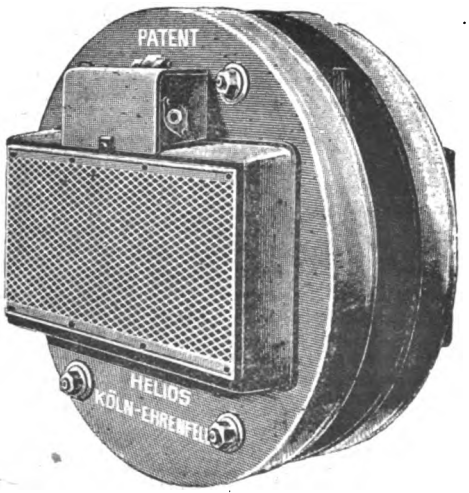

FIG. 4.—Step-down Transformer, Helios type, Kaiser Wilhelm Canal.

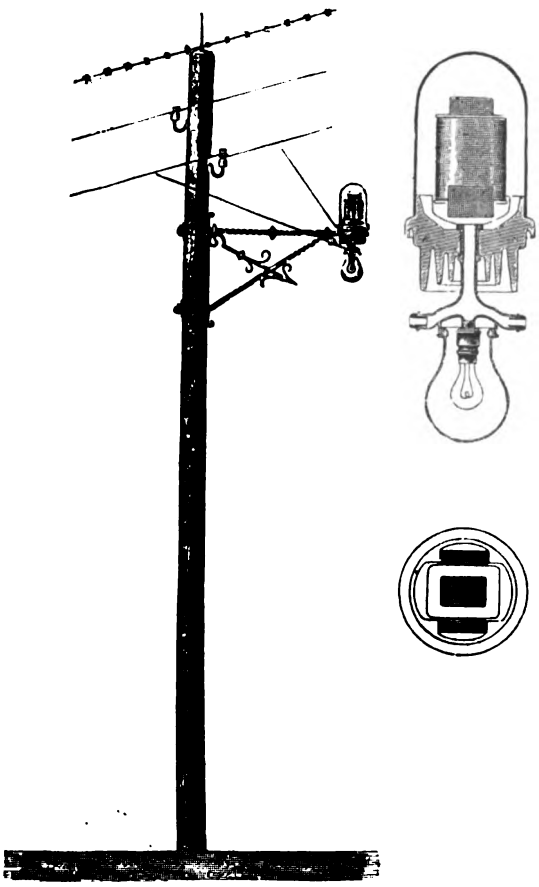
excitation, the pressure and current strength generated by the alternators, and also the watts supplied to the line. For paralleling purposes artificial resistances, consisting of asbestos ropes wound round with nickel wire, are provided. The phases are not only indicated by two lamps fed by a transformer with duplicate primary windings energised by both machines, but also by a phase indicator. This



FIGS. 5 AND 6.—Line Post and Lamp Details, Kaiser Wilhelm Canal.

latter consists of a movable disc pivoted in front of two magnet poles energised by both machines. If the phases of the two machines correspond, the disc remains stationary, but otherwise the disc rotates in the one or other direction in response to the leading phase. For the lighting of the station buildings, the primary current is transformed down to the required pressure by Helios transformers, of the type shown in Fig. 4. The lanterns employed for lighting the locks contain four 25-c.p. lamps each. The feeders are almost exclusively of the concentric armoured type. Both at Holtenau and at Brunsbüttel the lighting of the station buildings and locks is very effective, no lack of arc and incandescent lamps being apparent.

The 62 miles stretch of canal is divided into four distributing sections in such a manner that from Holtenau one of these sections extends along the north bank, and a second along the south bank of the canal to a point about 29½ miles remote from the station. At this point the remaining two sections commence, one following the north and the other the south bank of the canal to the second generating station in Brunsbüttel. Thus there are four lines of lamps, for each of which lead and return cables had to be provided. From Brunsbüttel to the central division point the aggregate length of the lead and return conductors along the north bank of the canal amounts to 62½ miles and along the south bank to 63 miles, while the Holtenau circuits have lengths amounting respectively to 62 miles and 61 miles along the north and south banks. To each of these four sections or circuits are connected 250 25-c.p. incandescent lamps, which gives a mean distance from lamp to lamp of 215 yards. As, however, the lakes which are intersected by the canal are not electrically lighted (the navigable channels through the lakes are marked by gas buoys at night), the mean distance between the lamps is really about 174 yards. As a matter of fact, the actual distance between the lamps varies from 85 to 270 yards, since where the course of the canal is straight the illumination given by the lamps placed at intervals of 270 yards is amply sufficient, whereas the distance between the lamps at curves had to be correspondingly less to obtain equivalent effect, the aim being to provide sufficient light at all parts of the canal to render its navigation by night safe and easy. The conductor employed for these circuits consists of 4mm. copper wire, and is supported overhead by double-bell porcelain insulators of the treble heavy type first introduced by the Helios Company. These insulators are in turn carried by stout posts of wood (Fig. 5), placed at intervals of 43½ yards. At the points where the lamps (Fig. 6) are connected the line is in no way broken, a choking coil being placed in parallel with each lamp. The ratios between the magnetic and electrical quantities of the choking coils and lamps respectively are so proportioned, that 9 per cent. only of the current consumed at each point is diverted through the choking coil so long as the lamp burns. Should, however, the lamps become defective, the whole of the current is then deflected through the coil, so that no interruption of the current can occur.

The proportions are so finely calculated, that of the 250 lamps connected up to each circuit over one-third may be destroyed or cut off without entailing any regulation whatever of the system from the generating station. The terminal pressure at each lamp amounts to 25 volts, in addition to which the great resistance offered by the conductor itself has to be overcome, the combined resistance rendering the maintenance of a constant pressure of about 7,500 volts at the generating station ends essential. This potential is obtained by transforming up the current generated by the machines, which, as previously mentioned, give a terminal pressure of 2,000 volts.

It may be added that the overhead system is protected from lightning by means of barbed wire. The conductors serving the north side pass under the canal and also under the various streams which flow through it, special sections of armoured cable being employed. These sections are buried to a depth of about 3ft. in the canal bed, and consist of two inductionless rubber-covered cables, with a further protection of guttapercha, and over that armour to preserve the whole from mechanical injury. No trouble has been experienced with the system, which may be said to have satisfied the most sanguine expectations. For this happy result credit must be duly accorded to the Helios Company, who were the responsible firm throughout. Great interest was taken by the Verband in the inspection of the installation in Holtenau, and all expressed their admiration of the arrangements seen there.

THE MUNICIPAL ELECTRICAL ASSOCIATION.

HUDDERSFIELD CONVENTION.

(Continued from page 16.)

As though to make up for the late hour at which the members went to bed after the dinner, the committee arranged that everyone should start for Leeds by the 9.30 a.m. train on Friday, June 22. When they arrived there, there was the usual heavy programme of papers to be read and discussed. The meeting-place was the Albert Hall, and Mr. Mountain took the chair almost punctually at 10 a.m.

The first subject brought before the meeting was the "Distribution of Electricity in Scattered Areas." There were two papers read in abstract on this subject, one by Mr. L. Andrews, of Hastings, and the other by Mr. G. Wilkinson, of Harrogate. The following are these papers *in extenso*:

The Distribution of Electricity to Scattered Areas.

BY L. ANDREWS, BOROUGH ELECTRICAL ENGINEER, HASTINGS.

A few years ago, if a scattered area was mentioned in connection with the distribution of electricity, everyone would have known, without further explanation, that reference was made to a district covering an area of a few square miles but very sparsely populated. At the present time, however, a scattered area to many electrical engineers means a district containing a number of towns, several miles apart, all supplied from one generating station. This paper will, however, be confined to the question of supplying electricity to the old-fashioned scattered area. It will also be old-fashioned in another respect, for it will deal with the old and many times discussed question of alternating currents *versus* continuous. Until comparatively recently the advocates of the respective systems have each been willing to admit that neither system was altogether best; that the system best for one town was quite unsuitable for another. But with the successful introduction of high-voltage lamps, many of the continuous-current advocates are again attempting to claim that there is not a town in the country that could not be more advantageously supplied by continuous currents than by alternating. Others, on the contrary, still contend that a large and scattered district can be fed more economically by high-tension alternating currents than by the extreme limit of low-pressure supply yet sanctioned by the Board of Trade.

To compare the merits of the two systems, it is necessary to consider (*a*) the relative capital outlay involved; (*b*) the relative annual cost of upkeep; (*c*) the comparative reliability of each system. Instead of taking a hypothetical case for these comparisons, it is proposed to consider the relative merits of the respective systems for the purpose of supplying current to a definite area—viz., that of the borough of Hastings. The cost of the distributing networks will not be taken into consideration, as it is assumed that it would be the same for either system. The positions of the feeding points on the distributing networks would also be approximately the same in either case. To provide for the immediate future requirements, 17 feeding points are required; these are generally from 800 to 900 yards apart. The generating station is in the centre of the borough and about 4,000 yards from the furthest feeding points. It is estimated that the average maximum demand on each feeder will be about 100 kw. The daily load factor will probably be about 10 per cent., or equivalent to 2½ hours daily use of the maximum demand. For the low-pressure scheme it is assumed that a single independent triple-concentric feeder would be run direct from the generating station to each of the feeding points; that all feeders in which the drop was less than 10 per cent. would be connected direct to the generating 'bus bars, which would be maintained at a pressure 10 per cent. above the declared pressure of 250 volts across each side of the three-wire system; that all feeders in which the drop exceeded 10 per cent. would be supplied from other 'bus bars boosted up to compensate for the increased drop, and that in all feeders in which the pressure at the feeding points exceeded the declared pressure by more than 2 per cent., a resistance would be inserted to compensate for the excess of pressure.

Table I. gives the actual length of the feeders required for lighting the district referred to, and other particulars *re* same.

For the high-pressure scheme it is assumed that a sub-station would be erected at each of the feeding points, and equipped with transformers to transform from 2,000 volts down to 500 or 250 volts; that instead of running independent feeders to each sub-station a pair of feeders in duplicate would feed five or six sub-stations, as shown diagrammatically in Fig. 1.

Table II. gives the size and length of feeders required for this purpose, and other particulars *re* same.

(*a*) *Capital Outlay.*—It is estimated that the capital outlay necessary to carry out the respective schemes referred to above would be as follows:

	L T. £	H.T. £
To cost of laying and jointing the undermentioned cables, complete with necessary trench work, troughing, and pilot wires, etc.:		
7,420 yards of ·036 high-tension concentric in duplicate, at 14s. per yard	—	5,200
2,700 yards of ·062 high-tension concentric in duplicate, at 18s. per yard	—	2,250
5,100 yards of ·15 high-tension concentric in duplicate, at 23s. per yard	—	5,870
1,000 yards of ·2 high-tension concentric in duplicate, at 25s. per yard	—	1,250
3,720 yards of ·2, ·1, ·2 triple concentric, at 14s.	2,600	—
7,300 yards of ·3, ·15, ·3 triple concentric, at 18s.	6,560	—
25,600 yards of ·4, ·2, ·4 triple concentric, at 22s.	28,180	—
To cost of building 17 sub-stations	—	1,700
To cost of 68 30-kw. transformers	—	5,100
To cost of sub-station switch gear	—	3,400
To cost of feeder switch panels at generating station	1,700	300
To cost of continuous-current boosters	1,950	—
Balance in favour of high-tension scheme	—	15,920
	£40,990	£40,990

(*b*) *Annual Cost of Upkeep.*—Under this heading the following items should be considered: (1) the interest and sinking fund on the capital outlay; (2) the cost of repairs and attendance to mains and distributing apparatus; (3) the cost of energy wasted in distribution. It is assumed that the interest and sinking fund would amount to about 7 per cent. per annum on the capital expended. The cost of repairs, etc., to mains is taken at 3 per cent. per annum in the case of the high-tension scheme, and 2 per cent. per annum for the low-tension scheme. In considering the third item, the energy wasted in distributing networks, meters, etc., is not taken into account, as it is assumed that these losses would be practically the same for

Digitized by Google

either system. The C^2R losses in feeders are obtained from Tables I. and II. The transformer losses and capacity losses in connection with the high-tension scheme, are based upon recent tests. The above losses for the district and output referred to may be summarised as follows :

	L.T. Kw.	H.T. Kw.
Full-load losses :		
C^2R losses in feeders	224	60
Capacity current and transformer losses	—	60
Total full-load losses	224	120
One-third full-load losses :		
C^2R losses in feeders	25	7
Capacity and transformer losses	—	38
	25	45
One-tenth full load losses :		
C^2R losses in feeders	2	·6
Capacity and transformer losses	—	30
	2	30·6
No-load losses	0	30
	L.T. B.T.U.	H.T. B.T.U.
Daily losses :		
Full load one hour per day	224	120
One-third load four hours per day	100	180
One-tenth load one hour per day	2	30
One-fiftieth load 18 hours per day	0	540
Total daily losses	326	870

It will be seen that in spite of the very great improvements in modern transformers, the all-day losses in connection with the high-tension scheme are still very high. These may be reduced by turning off a number of the transformers during the hours of light load. But even if they are all turned off, the losses through capacity current in the feeders will still be very high. It is suggested that in some districts where the day load is always likely to be a very light one, and where, as at Hastings, it is chiefly confined within a radius of about 1,000

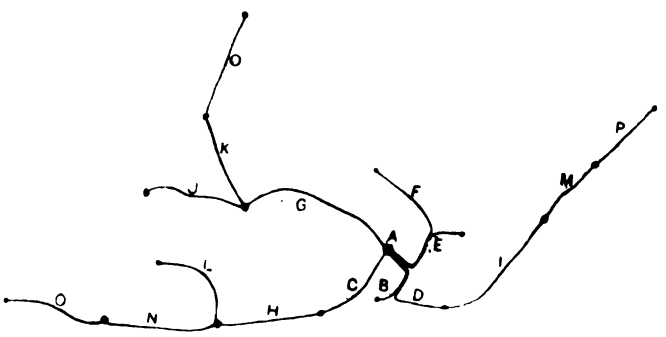

FIG. 1.

yards of the generating station, it would pay to disconnect the whole of the high-tension feeders, etc., during the hours of light load, and supply all current required through the distributing networks. If this can be done, it is estimated that the high-tension losses during the hours of light load will be reduced from 540 units per day to about 40 units per day. The relative annual losses of the respective systems would then be as follows :

Low-tension	326 units per day × 365 = 118,800
High-tension	370 units per day × 365 = 134,500

The cost of generating the above wasted units will be as follows :

	L.T. £	H.T. £
To stand-by charges :		
224 kw., at £5 per kilowatt	1,120	—
120 kw., at £5 per kilowatt	—	600
To running charges :		
118 800 units, at 1½d	618	—
134,500 units, at 1½d	—	700
	£1,738	£1,300

The total annual cost of upkeep will, therefore, be as follows :

	L.T. £	H.T. £
To interest and sinking fund :		
7 per cent. on £40,990	2,866	—
7 per cent. on £25,070	—	1,754
To repairs and attendance to feeders and other apparatus :		
2 per cent. on £40,990	820	—
3 per cent. on £25,070	—	752
Rent of sites for sub-stations	—	30
To cost of current wasted	1,738	1,300
Balance in favour of high-tension scheme	—	1,588
	£5,424	£5,424

(*c*) *Comparative Reliability.*—Doubtless continuous-current advocates will say that, on this score at any rate, the advantages are entirely with their system. It must certainly be admitted that in the past low-tension schemes have not suffered from breakdowns to quite the same extent as high-tension schemes ; but greater liability to breakdown does not necessarily mean a greater number of interruptions to the supply. If high-tension apparatus and feeders are efficiently duplicated throughout, a failure in any portion of the system will not cause an interruption to the supply in any district. It may very reasonably be objected that duplication costs money, but it has already been shown that an high-tension scheme duplicated throughout costs considerably less than an unduplicated low-tension scheme. It is not, however, sufficient to merely provide duplicate apparatus to be switched into use if necessary. The duplicate feeders, etc., must be connected in such a manner that in the event of a failure the faulty section will be automatically disconnected from the system, the duplicate feeder being left to maintain the supply. A satisfactory method of effecting this object is described in the author's Institution of Electrical Engineer's paper, "The Prevention of Interruption to Electricity Supply."

Figs. 1, 2, 3, and 4 illustrate the manner in which this special system of duplication is being applied at Hastings. Fig. 1 shows the general arrangement of the high-tension circuits. Fig. 2 is a diagram of the connections, both primary and secondary, in the sub-stations. In this diagram, F and F 1 represent the duplicate high-tension feeders entering the sub-station from the generating station. F 2 and F 3 are similar feeders leaving to supply other sub-stations. D 1 and D 2 are high-tension discriminating cut-outs connected to the

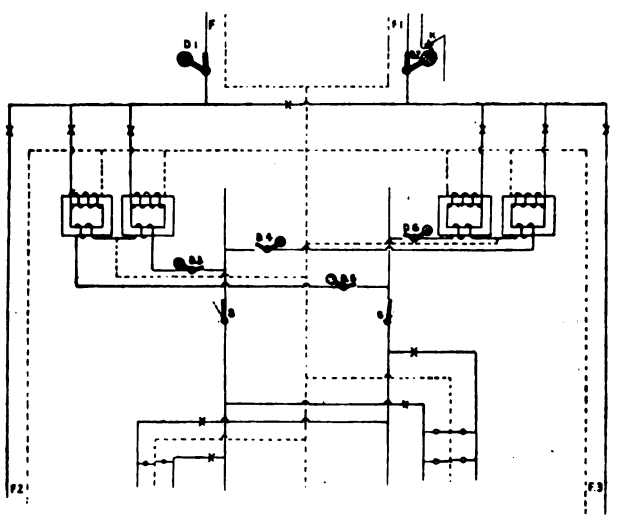

FIG. 2.

end of each feeder to prevent a heavy current from returning *vid* the sub-station to supply current to a faulty feeder. D 3, D 4, etc., are similar cut-outs on the secondaries of transformers. These serve to disconnect a faulty transformer from the secondary 'bus bar, and so prevent it from short-circuiting the remaining healthy transformers. S S is a double-pole switch inserted in series with the secondary 'bus bar. By opening this switch the secondaries of all transformers are disconnected from the distributing network. Fig. 3 shows the general arrangement of the distributing networks throughout the town. It will be seen that each distributor with its branches runs from one sub-station to another, and as all distributors are heavily fused at each end, it follows that a very heavy short-circuit on any section of the network will cut the distributor effected free from the rest of the system. The district supplied is divided into four distinct secondary networks. Each distributor is connected, either directly, or *vid* other distributors and sub-stations, to the generating station. One object of this arrangement is to enable the entire district to be supplied during the hours of light load by means of the secondary network only. Reference was made to the saving effected by this earlier in this paper.

To derive the greatest benefit from the turning off of transformers and feeders, it is necessary that this should be done as soon as the load falls below a certain point every night, and they should not be turned on again until the load begins to rise. The former it is comparatively easy to arrange, as turning off time will occur approximately the same time every night. But the time at which the transformers, etc., will need to be turned on will vary from day to day, and will also depend to a great extent upon the weather. It will often, too, need to be done at a moment's notice. It is advisable, therefore, that the turning on should be done from the generating station. The way in which this will be effected at Hastings is shown in Fig. 4. From each sub-station a pilot wire, P, will be run direct to the generating station. This pilot wire will be used for the following purposes : (*a*) to indicate on a voltmeter at the

Digitized by Google

generating station the pressure at the sub-station to which it is connected; (*b*) to indicate at the generating station the position of any fault in a transformer or feeder; (*c*) to indicate at the generating station when the secondaries of the transformers have been disconnected at the respective sub-stations; (*d*) to enable the secondaries of transformers at the sub-stations to be switched on to the distributors from the generating station.

(*a*) *Pressure Indication.*—The pilot wire is connected to one of the outer wires of the three-wire system at the sub-station, and the circuit is completed through the pilot wire, P, a two-way switch, D, and voltmeter, V, to the neutral or middle wire, B, at the generating station.

FIG. 3.

(*b*) *Fault Indication.*—A small auxiliary switch is attached to each of the discriminating cut-outs in such a manner that it is opened or closed by the opening or closing of the cut-outs. These auxiliary switches, K K 1 and K 2, are all connected in series with the pilot wire. Should, therefore, a fault occur in any high-tension feeder or in a transformer, the cut-out directly connected to it will be opened thereby, and since this will open one of the auxiliary switches in series with the pilot wire, the position of the fault will be signalled to the works by the needle of the voltmeter connected to the sub-station affected by the fault falling to zero.

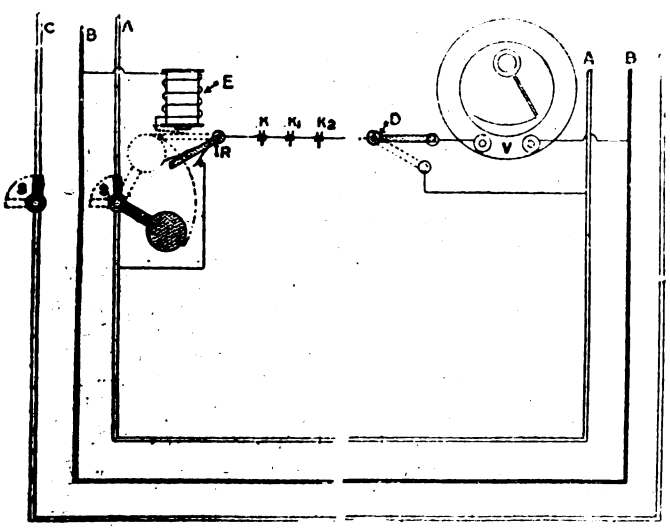

FIG. 4.

(*c*) *Indication of the Cutting off of Transformers.*—Between 11 and 12 p.m. it is intended to send one or two of the running staff, who can conveniently be spared at this time, round to the various sub-stations to switch off the transformers. This will be done by means of the double-pole switch, S S (Figs. 2 and 4). This switch is weighted in such a manner that it tends to stay closed. By lifting the weight the switch is opened, and it may be kept opened by means of a small catch, R. The action of lifting the weight to open the switch, S S, lifts the catch, R, and so interrupts the pilot wire circuit, and the voltmeter needle falling to zero indicates that the transformers at the particular sub-station have been disconnected from the distributing network. When the whole of the transformers at all the sub-stations supplied by a feeder having been disconnected, the feeder is itself disconnected at the generating station, thus cutting off all the primaries.

(*d*) *Switching on Transformers.*—When it is desired to switch the transformers on to the distributing network, the switch, D, at the generating station is placed over to make contact with the wire A. As the pilot wire at the sub-station end is connected to the neutral wire, B, through the catch, R, and coil, E, a current will now pass through the coil, E, and release the catch, R, allowing the weight to fall and close the switch, S. If the switch, D, is now replaced so that the pilot wire is connected to the voltmeter, V, this instrument should then indicate the pressure at the transformer station. The reading of the voltmeter will be a reliable indication that the switch, S S, has operated satisfactorily.

Distribution of Electricity.

BY G. WILKINSON, BOROUGH ELECTRICAL ENGINEER, HARROGATE.

The subject of the distribution of electrical energy is such a wide one that I cannot hope to treat it exhaustively in a paper of the required dimensions for this association. The question of size of conductors, types of insulation, methods of laying, regulation of pressure, methods of testing, and kindred subjects would each form an ample and appropriate theme for a paper under the above general heading, but the object of this paper is to bring before the members of this association certain practical difficulties and suggestions upon this important branch of the electric supply business which has hitherto been somewhat neglected in favour of more interesting but possibly less important engineering and electrical details. If the responsibility of an electrical engineer ceased at the 'bus bars in the works, his lot in life would be a happier one than it is at present; given good design of plant, sufficient boilers, engine and dynamo power, average care and intelligent supervision at the generating station, a steady electrical pressure and a constant supply of current is assured.

It is undoubtedly in the distribution of the electrical energy from the generating station to the consumers' premises that the greatest risks of failure of supply occur, and it is this department of the undertaking which is fraught with most risk. Here failures of a more or less serious nature are liable to occur at any moment, often without the slightest warning, occurring at widely-varying periods of time, usually during wet and unfavourable weather, and possibly at a time of night or early morning when it is desirable to be in bed or, at any rate, free from the cares and worries of business. It is not comfortable for any engineer to feel that, notwithstanding the exercise of due care and forethought, a bad fault may develop upon the mains at any moment, and effectually stop the supply of electricity to a large proportion of the consumers. Such interruptions of supply serve to destroy public confidence, cause a large amount of loss and inconvenience, and reflect more or less upon the ability of the engineer. Against faults on mains, the possession of accumulators provides no remedy, and assuming a proper subdivision of plant with an adequate reserve of power at the generating station, accumulators are not regarded as such an important adjunct to a station as they used to be, nor are they likely to assume an important place in large undertakings until they are much improved, reduced in price, less troublesome in upkeep, and of higher efficiency. It should be one of the prime motives of an engineer to make his distribution system safe and reliable under every

Digitized by Google

possible condition that can arise; no spirit of parsimony on the part of those in authority should prevent him obtaining and putting down the very best cables and joint-boxes money can buy. So far as experience has hitherto shown there is no difficulty in obtaining a variety of types of reliable cables; there are at least half-a-dozen good makers in this country, and there are as many systems of laying mains to select from, while the types and varieties of joints, joint-boxes, and accessories thereto in use are far too numerous.

For low-tension direct-current distribution recent practice has led to the almost universal use of three conductors laid side by side in the same trench, and they usually fall under one or other of the following types: (1) bare conductors carried on earthenware or glass insulators within concrete, brick, or iron conduits; (2) three insulated single conductors laid in troughs and run up solid with bitumen; (3) concentric cables, armoured, and laid directly in the ground; (4) single cables, drawn into stoneware, concrete, or bitumen conduits; (5) three-core "clover-leaf" cable, armoured, and laid directly in the ground. No. 1 is a method of distribution which is unsurpassed for durability and simplicity, and for low-tension currents it appears to be perfectly reliable, provided the conduits are kept clear of water. It can be highly commended on account of the ease and small cost of connecting consumers' installations with the mains; the service mains can be soldered to the supply mains at any point, and no joint-box is required. Notwithstanding these substantial advantages, this system appears to be making little, if any, headway owing to the difficulty of finding room for it under the street pavement, besides which owing to the cost of the conduits and supports it is probably not economical in first cost for conductors of less than ·1 square inch section, which is too large a conductor for the less important streets. I believe there are few engineers more favourably impressed by this system than Mr. Wordingham, but according to the returns published in his paper on "The Distribution of Electrical Energy," read before the Northern Society of Electrical Engineers, he has less than 6½ miles of this class of mains laid down in Manchester out of a total length of nearly 32 miles of distributing mains. The St. James's and Pall Mall Company at the commencement of their works used bare conductors laid in iron conduits very largely indeed, but there have been no extensions thereto during the last seven years, bare conductors having been discarded in favour of armoured insulated cables laid directly in the ground. Method No. 2 appears to be the most widely used system for the distribution of low-tension direct current, and possesses the important quality of durability with facility and cheapness of jointing service cables. No mechanical joint-boxes for service mains are necessary, the service cables can be soldered directly to the distributors at any point, the joints being insulated and the trough refilled with the waterproof bitumen. The troughs should in every case be covered with cast-iron covers to afford protection at the top and sides against mechanical injury, and the services used in connection with this system should also be enclosed in troughs and run up solid with bitumen, the whole being protected by metal covers. Experience in many towns appears to show that a carefully-laid network upon the solid system is remarkably free from faults. Methods Nos. 3 and 5 have been largely used, but they do not appear to possess the qualities of durability and permanence equal to methods Nos. 1 and 2, as the steel sheathing is liable to rapid corrosion in wet ground, but given freedom from mechanical injury the life of these cables is probably measured by the life of the lead covering in which they are enclosed; what length of time this represents there is as yet no experience to show. The recent practice of putting lead sheathing cables into earthenware ducts, and covering them with a continuous coating of bitumen, will doubtless increase the durability and life of the cables. Method No. 4 the writer regards as only suitable for feeders from the station to the various distributing centres. A good method is to draw feeders into some form of conduits, from which they can readily be withdrawn in case of a fault or for the substitution of a larger main to meet an increasing demand. The feeders should be laid in the longest lengths possible, so as to reduce the number of joints to a minimum. These joints in all cases should be readily accessible for examination, testing, or repairs.

For alternating currents armoured concentric cables are most frequently used as low-tension distributing mains, and give the most satisfactory results. Clover-leaf three-core and triple-concentric cables, armoured and laid directly in the ground, are also largely used. The three-core cable is somewhat more expensive in first cost than the triple cable, probably because it is not manufactured in such large quantities; it has, however, the advantage that the service joint-boxes and connections are much cheaper. A service joint-box for a triple main costs from £2 to £3. 5s., as against the half the cost for a service joint-box and connections for three-core cable of the same size; in addition to this, the triple-concentric box costs more in labour to joint. This means an average saving with three-core distributors of over 25s. for each service connected, or where two services are taken from the same box 12s. 6d. per service, which is a very substantial saving, especially in the total cost of connecting up small consumers. With triple-concentric distributors, it is necessary at every other service connection to cut through the outer and middle conductors to make joints on the inner and outer conductors, the alternate joints being made to the outer and middle, leaving the inner conductor intact; in many triple-service joint-boxes it is necessary to cut all three conductors at every joint, and this constant cutting and the frequent insertion of mechanical junctions doubtless tends to impair the conductivity of the main. In some towns, to avoid cutting the middle conductor, the triple-concentric distributors have been divided up into sections, each section being connected by a junction box which changes the polarity of the inner and middle conductors, so that the middle will be + on one section and − in the next; all joints are made upon the middle and outer conductors only, while the balance of load is thus kept approximately equal on the two sides of the neutral or outer conductor. Probably the advent of higher-voltage lamps, and the consequent raising of the electrical pressure upon the distributors, will lead to simple concentric main entirely superseding both the three-core and triple mains for alternating-current distribution purposes. For high-tension distribution, concentric mains have demonstrated their superiority over side-by-side cables, both in point of efficiency and safety.

For high-tension currents it is difficult to conceive a safer method of distribution than by concentric mains with the outer conductor earthed at the station, and the writer has known numerous instances where 2,000-volt mains have been sawn asunder by careless jointers with the current on, always with disastrous result to the saw, but with no inconvenience to the jointer beyond a blinding flash when the saw has reached the inner conductor. As a dielectric for high-pressure mains, paper impregnated with oil appears to be the most satisfactory; it possesses great resistance to electrical stresses, has sufficient flexibility if the cable is carefully handled, and the conductors can be heated to a considerable temperature before any damage is done to the insulation, which is a great advantage when sweating joints, or in case of having to overload a cable for the purpose of burning out a fault. Owing to the hygroscopic nature of the dielectric, it is necessary that the cable be enclosed in a continuous metallic envelope to keep out moisture, and this appears to be the one weak point in paper-insulated cables, though the writer has only had two instances during a long experience in which paper-insulated mains have failed owing to blow-holes in the lead covering.

Joints and Jointing-Boxes.—Probably in no branch of electricity supply undertakings is more variety of design manifested than in the matter of joint-boxes. Many engineers design their own joint-boxes, and will employ no other type. Some of these boxes are of good and reliable design, and a fair proportion of them are faulty and unreliable. Owing to the almost numberless designs of boxes used in the country and the consequent limited demand for each pattern, the cost of joint-boxes must necessarily remain high, and, in the writer's opinion, it is time an effort was made to secure standard types of joint-boxes and connections for all classes of cables, which shall be recognised as most suitable and reliable for the particular purpose for which they are designed. Until there is more uniformity of design and standardisation in joint-boxes, disconnecting boxes, house service boxes, terminal boxes and their accessories, the cost of connecting consumers' premises to the supply must remain high, and we cannot hope to be free from interruptions of supply, which, though happily in most cases occurring only at long intervals, constitute a continual source of anxiety to the engineer, and in the past have served to confirm a general impression in the mind of the public that electricity supply is unreliable, and should not be entirely depended upon either as a source of power or illumination. In the case of low-pressure supply network employing single cables, the question of joints is not serious or difficult, and probably the best form of joint is an ordinary "married" and soldered joint well lapped with insulating strip enclosed in a substantial iron case and run up solid with a waterproof bituminous compound, or, in the case of rubber-insulated cables, covered and vulcanised. For economical reasons the joints on low-pressure mains are buried beneath the pavements, and any faults which may develop are difficult to find; for this reason at every street corner an accessible distributing box should be provided, at which the network can readily be disconnected and divided up into short lengths, enabling faults to be quickly located and repaired before they became serious. The pillar distributor designed by Mr. Wordingham for Manchester is admirably adopted for this purpose. The apparatus consists of a central iron pillar within the junction box supported upon insulators. This pillar carries an iron plate for each pole; on each plate is fixed a ring-shaped porcelain insulator carrying a gunmetal ring having projecting studs, to which the cables can be clamped by means of nuts, the ends of the cable being sweated into lugs. A large funnel is slipped on to the top of the pillar and serves to collect any water that may drip into the junc-

Digitized by Google

tion box, and so prevent it from falling upon the connections. Owing to experience obtained with fuses on mains, which were always put in too light, there appears to be a wide and well-founded prejudice against the use of underground fuses, especially in big undertakings, where owing to the development of a fault upon a main such a heavy flow of current will take place through the main as to permanently damage the insulating covering thereon from excessive heat; under such conditions the conductor of smaller section would be fused before damage were done to the insulation of the main, and at the same time the faulty circuit would be isolated from the remainder of the network, and prevent failure of supply on other mains in the immediate district. This is simpler, cheaper, and more reliable than employing automatic devices to break circuit with excess of current; and such automatic devices are subject to rapid deterioration when put underground, are liable to stick at the critical moment or to open the circuit when it is not desired or necessary. In joint-boxes for concentric cables the prevalent method of clamping up the outer conductors upon the insulation of the inner conductors should be condemned, as no permanently good connection can be made upon a more or less soft and elastic substance forming the insulation. The unsatisfactory makeshift of slipping a split ferrule in between the outer conductors and the inner insulation should also be abandoned, as seldom is a sound metallic contact upon all and every outer strand of the outer conductor secured by this method; the outer conductors often being hard bound in one diameter and loose in the diameter at right angles, thus in course of time, when the main becomes loaded to its full working density heating is likely to take place at these contacts, the joint becoming impaired, and the resistance of the main increased. In every case the "outers" of concentric or triple-concentric mains should be bent out at right angles radiating from the centre of the cable, and be securely clamped between two discs of metal, which also form the necessary connections in the joint. By this means a good contact is maintained between each and every strand of the outer conductor. If these discs of metal are made whole, the centre conductor requires to be cut in order to get the discs into position, which is not good practice, although often resorted to. To avoid this, the discs should be made in halves, the division line of the front disc being set at right angles to that of the back disc, thus securing rigidity and good conductivity when fixed. For the same reason, all joint-boxes for mains should be made in halves—*i.e.*, divided horizontally in the plane of the cable—otherwise the mains have to be cut to get the joint-boxes on, which is a common though bad method.

The writer wishes to enter a protest against the far too lavish use of compound in joint-boxes. Waterproof bituminous insulating compound is a very useful and necessary article to the jointer, but it is a mistake to run up a mechanical joint-box solid with this substance; the connections within the box should be enclosed in a light internal box, preferably of incombustible material, to keep the compound off the connections, and the compound should be run in solid between this internal box and the outer box. The difficulties of clearing the connections of this compound when once they are run up solid in it are very great; the compound is seldom brittle enough to chip out with hammer and chisel, consequently it has generally to be melted out with a blow lamp. As everybody of any experience knows, this is a very tedious process, and unless great care and judgment are exercised the insulation of the incoming cables is damaged by the heat; such work as this has generally to be done when there is a fault on the main, and it makes it impossible to effect an expeditious repair, whereas if the compound simply formed a shell round the joint between the outer joint-box and a fragile inner box, the joint could be quickly cleared and the connections readily exposed for the necessary examination, alteration, or repairs. The author would like to see the prevailing custom of using wood or fibre boards in joint-boxes superseded by the use of earthenware or other incombustible material having satisfactory insulating qualities; combustible material in house switches, fuses, and distribution boxes has long been superseded by the use of porcelain, and possibly the same improvement will take place in underground joint-boxes when a serious effort at standardisation has been made. Experience has demonstrated to the writer that in many instances substantial improvements can be effected in joint-boxes if the cable ends to be joined are turned into a vertical position and enter the joint-box from the bottom. This method, which was a radical departure from the prevailing practice of that day, was probably first introduced by Mr. J. S. Raworth in 1892 on the high-pressure concentric mains laid in Huddersfield. In this case the mains are brought through glands in the bottom of a circular cast-iron base, the glands being made watertight round the cables by means of wax, thence through a disc of porcelain fixed on the said iron base and carrying the connections for the "outer" conductors; the "inners," being carried up still higher in the box by their own rigidity, support the "inner" connections, which are fixed by suitable screwed clamps to the ends of the "inner" conductors, the said clamp connections being covered by an inverted cup insulator formed of woodite. The whole joint-box is covered by a dome-shaped cast-iron cover, the lower edge of which dips into a faucet cast round the circular iron base, where it is made air and water tight by a filling of wax. This joint-box was a great advance upon many of those in use at that time for the following reasons: (1) it is easily accessible; (2) the removal of the dome-shaped cover immediately exposes all the connections for examination or manipulation; (3) the insulation of the joint is high; (4) little, if any, combustible material is used in the construction of the box; (5) the joint-box is cheap and the parts interchangeable. Joint-boxes of this type are used by Prof. Kennedy upon the low-pressure mains in Sunderland and Edinburgh, in which the ends of the single cables are turned into a vertical position and fitted with metal cone-shaped connectors; these connectors are screwed up to a heavy horizontal connecting bar, the whole being covered by a dome-shaped cover of porcelain. Four, five, or six way boxes are also used of similar construction. There may be other towns in which this class of joint is used, and probably its use will become more general in the near future for many classes of cables, owing to the simplicity of the method and the considerable advantages obtained thereby. At all points where the Raworth high-tension joint-box is used it is necessary that the cable ends be left long enough to overlap each other so as to allow enough spare cable to enter the box and reach the connecting bars, also the connections within the box are so close together that the joint is practically useless as a disconnecting box during period when the cables are carrying current.

The writer is using a reliable and inexpensive high-tension box of this type with very satisfactory results. This joint-box is cast "coffin" shaped—viz., long in one diameter and narrow in the other—in order that it may be placed upon any cable which is already laid; and by reason of the centres being wide apart in one diameter, any cable is long enough to reach up to the box terminals, provided the cable is cut at point midway between the two centres. This coffin box is supported with the outer metal pavement box just below the pavement level by means of brackets, which not only carry the joint-box, but also grip the outer lead covering of the cables, thus effectually earthing both the inner and outer boxes, and maintaining the cable ends in a vertical position at the proper centres and attitude for entering the taper glands in the bottom of the joint-box. The joint-box lid, which is shrouded round the rim, is secured by means of swivelled bolts and wing nuts, and is made watertight by compressing an indiarubber ring between the lid and box rim. It will thus be evident that the joint-box is in the best possible position for accessibility. It is above the plane of the conduits and cables, and forms no obstructions to the drawing in or manipulation of additional mains; also the joint is well above any lodgment or flow of water in the conduits or joint-pits; this latter is a valuable feature in view of the number of faults which so frequently arise through water getting into joint-boxes. The box carcase is cast so that it may be used either as a straight-through or three or four-way box, as desired. The outer conductors, after the cables are brought through the bottom of the joint-box, are spread out radially and clipped in between contact discs, the said discs being connected together by suitable connecting links, and upon each upper half of the contact disc bosses are cast, into which externally fluted hollow earthenware insulators are screwed; through these insulators the inner conductors with their insulating coverings are brought, and the inner conductors are attached to the metal terminal discs fixed on the top of these earthenware insulators. These "inner" terminals are made in various designs, according to the particular use for which the box is required, and in due form an "inner" connecting bar is used, forming a first-rate quick-break switch, which may be pulled out or replaced with perfect safety at full load should such an operation be necessary. A watertight compound is used only for luting up the conical cable glands in the bottom of the box, the whole of the internal connections being thus left exposed for examination, testing, or repairs. These boxes in any size up to 300 kw. size—viz., 150 amperes at 2,000 volts—complete with all accessories, including outer box, fixing in the pavement, jointing up, jointers' time, and all labour, cost less than £5. 5s. each, while the cost of brick pit and pavement cover alone for many types of boxes exceeds this figure. In the writer's experience, previous to the introduction of this type of high-tension box, the cost of brick pit, pavement frame, cover, and internal joint-box for concentric cables, including labour, fixing, and jointing up, was never less than £7. 7s. 6d. Doubtless in the near future triple mains of the "clover-leaf" type will be extensively used for power transmission through long distances by means of multiphase currents at extra high pressure. For these mains joint-boxes of the type just described possess valuable features, as they may be depended upon to stand any practical working pressure with safety, all the internal parts can be formed entirely of incombustible and durable material, and all inflammable compound may be entirely dispensed with. Another form of joint on concentric mains which should be mentioned is the simple soldered and wrapped joint, which is

Digitized by Google

protected from moisture by covering lead sleeve of larger diameter than the lead tube covering the cable, and to which it is united by plumbers' wiped joints; this form of joint when carefully made appears to be reliable, but no engineer would entertain the idea of using this class of joint exclusively on a distributing network.

A fruitful source of trouble and failure on high-tension alternating-current networks laid in residential neighbourhoods arises in the connections made between the concentric mains and the terminals of the small transformers installed in the houses. Usually the concentric mains are taken into a small joint-box, and united therein to "side by side" rubber-covered mains, which in turn are taken to the primary terminals of the transformers. In cases of this kind the writer has, by means of a special cable terminal end and cover, always concentric mains directly to the terminals of the transformer without the intervention of a joint-box, and in no single instance has a fault ever developed.

The discussion on these papers was opened by Mr. J. F. C. SNELL, who proceeded to dissect Mr. Andrews's figures as to the advantages of alternating currents. He also strongly criticised the figures in Mr. Andrews's paper as to the cost of direct-current feeders, on which cost comparison was made between the relative advantages of the two. Mr. Snell contended that the total cost of the feeders and switch gear for the direct current would not be more than £25,800 in the case taken by the author. This would be quite sufficient for a station with 1,700 kw. of plant. Again, he thought that the author's estimate of £100 as the cost of a sub-station was too low. Mr. Snell's conclusion as to the comparative cost of the distributing system with alternating and direct current respectively, was that there was nothing to choose between them. There was, however, an advantage in favour of the direct current, he thought, in the cost of upkeep. He complained that Mr. Andrews had given the total losses with the direct-current system, and yet had assumed reductions in his alternating-current system which had not been realised up to the present. He considered that a 2 per cent. charge for the cost of upkeep on the cost of direct-current feeders was too high, and from eight years' experience thought that 1 per cent. was ample. If corrections were made in this way, it would bring the cost of the two systems in Mr. Andrews's paper to very much the same.

Mr. COWAN said that in abstract this subject had been discussed quite sufficiently, but there was great need for practical discussion of the details which went to make up the actual cost. There was a strong feeling in favour of doing without transformers and the high tension. The direct-current system also gives them other advantages beyond the supply of light, in that they could supply motorcars, which he thought would be a profitable business in the future. As regards the cutting off the transformers in order to reduce the no-load loss, he did not think it was convenient. The supply of lighting along a long route, such as was shown in the author's plan, with transformers along it with both their high and low tensions connected in parallel, was not likely to give good regulation. He thought that the transformer in the sub-station marked B would be overloaded, and that in the sub-station marked P would be underloaded. They ought to be exceedingly careful not to switch off the high-tension feeders abruptly, as that caused a very high voltage due to surging.

Mr. C. H. WORDINGHAM agreed with Mr. Snell's comments on Mr. Andrews's paper. They had heard a discussion on the relative advantages of high-tension alternating currents and low-tension continuous currents for distribution, but he thought that the advantages of high-pressure continuous current should also be taken into consideration, as under certain circumstances this system gave more favourable results than those under discussion. With respect to Mr. Wilkinson's paper, it was not, of course, economical to put down a system of bare copper mains when only a certain section of copper was required. He thought that about a quarter of a square inch was about the minimum. In Manchester they were running bare copper to all the outlying districts where there was room under the pavement. With respect to the mechanical protection for conductors laid on the solid system, he found that a thick pitch-pine cover was the most serviceable, and that it would prevent any pick from damaging the cable. He would like to raise the question as to why metallic envelopes must be provided round cables that have a hydroscopic insulation, as stated by the author. He did not see why an insulating envelope which was waterproof could not be used.

Mr. H. FARADAY PROCTOR said that they had some 50 sub-stations in Bristol, and the cost of them did not average more than £70 each. With respect to Mr. Wilkinson's paper, he did not see any good reason or advantage in giving up the three-wire system in favour of the two.

Mr. W. A. CHAMEN said that while the bare copper mains had advantages, there were certain districts where they could not be laid. Glasgow was one of these, as the law in Glasgow allowed anyone to build a cellar under the footpath, which would entail a frequent moving of mains already laid. The Glasgow subsoil was also exceedingly wet. He had tried two systems of laying cables on the solid system—in one case iron troughs, and in the other earthenware. He found there was a tendency in certain cases for the current to get through from the lead to the iron trough. On the whole, he rather preferred the wood troughing.

Mr. A. S. BARNARD, of Hull, said it was known he had charge of a high-tension continuous-current system. They had four sub-stations, and arranged the switch gear so that they could switch in rotary transformers from the electricity works. He thought this also might be done with the alternating currents.

Mr. G. M. HARRISS asked why concrete ducts could not be formed in the streets in which to lay the cables on the solid system?

A member from West Ham here interposed with some remarks on the overpaying of the employés in the electricity works, but was reminded by the Chairman that the discussion was on the distribution of electricity over scattered areas. Mr. Mountain refused to see that the labour question had anything to do with the problem being discussed, and the member in question had thus to go back to West Ham without being relieved of his valuable speech.

Mr. L. ANDREWS, in reply, answered in part the criticisms brought against his paper by Mr. Snell. He thought that the number of feeding points he had allowed for would be wanted in practice in order to give good regulation. In Hastings they had recently signed a contract for the construction of a sub-station for £80.

Mr. WILKINSON, in reply, said that the continuous current of low-pressure system was too costly at first in scattered areas. He quite agreed with Mr. Wordingham's remarks respecting the envelopes for the hydroscopic cables, but knew of no insulating material which could be used to replace the lead.

(*To be continued.*)

THE TRAMWAYS AND LIGHT RAILWAYS EXHIBITION.

(*Concluded from page 21.*)

Messrs. R. Blackwell and Co. had on exhibition a large exhibit, in which were four trucks of the Peckham type. The Peckham "Standard" truck shown was designed for heavy 18ft. to 20ft. open cars. Its side frames were constructed with upper members for supporting the car body springs, and a lower compression member for supporting the end extensions of the upper members of the side frames. The car-supporting springs consist of four full elliptic springs located on the end extensions as near as possible to the pedestals, and eight coil springs located four inside and four outside of the pedestals. The other trucks were an "extra long" single truck and two double trucks, one a maximum traction truck and the other a short wheelbase swing bolster truck fitted with the Price friction brake. Samples of trolley wire and insulators were shown, and four types of trolley poles as supplied to various English corporations. Other interesting objects exhibited by this company were rail bonds, switches, car fenders of the "Hipwood-Barrett" and "Dover" types, a single-truck top-seat car capable of accommodating 53 passengers,

Digitized by Google

and special track construction with joints and crossings with specially hard manganese steel centres.

Mr. Harold P. Brown exhibited a special type of rail bond invented by Mr. T. A. Edison and Mr. Brown. It is stated to be a great improvement over other rail bonds. Rail joints with these plastic rail bonds were shown. There was also shown an Eddy dynamo of 3,000 amperes capacity, and meters of various kinds.

The Electromagnetic Traction Company showed a new system of electrical traction, constructed on the closed-conduit surface-contact system. The system, which, we understand, was invented by Mr. Lane, of the Birmingham Tramways Committee, consists of a flexible magnetic electrical conductor resting normally on insulators within an hermetically sealed conduit. The conduit is made of a non-metallic metal or alloy. Into the upper surface of the conduit soft-iron pole-pieces are secured in "dovetail" sockets with insulating cement. The upper surfaces of these pole-pieces are level with the surface of the roadway; the lower extremities of the pole-pieces penetrate into the conduit, but normally do not touch the flexible conductor, which is charged with current from suitable feeders. The conduit is filled with coal gas or other gas free from oxygen, which preferably has a reducing effect. The gas is dried by passing through unslacked lime or other desiccating material. The tramcar of this system is provided with an electromagnet, which is in such a position that it passes near to the pole-pieces of the track. The magnet is also fitted with a metallic brush, which touches the pole-pieces. A small accumulator is carried on the tramcar.

The Chloride Electrical Storage Syndicate exhibited samples of storage batteries as used for pressure regulation on numerous electric tramways and railways throughout the world. The various examples of different sized cells at present working in connection with electric tramway systems in Great Britain were specially distinguished, in order that people might see what was used in Great Britain.

The Electrical Power Storage Company also showed a number of their E.P.S. and other types of accumulators, these being too well known to need description.

Messrs. Askham Bros. and Wilson had a large exhibit of tool steel, platelayers' tools, carts for carrying rails, tramway points, and also patent movable points, tramway wheels and axles, cross-over castings, tie-bars, fishbolts, springs, etc. The joint-plates which were shown were of three types, and were fitted to rail sections as in use in Glasgow, Halifax, Aberdeen, Sheffield, and other towns.

The Simplex Steel Conduit Company's exhibit consisted of a board mounted on a framework, and on which were shown specimens of the company's conduits and fittings. In the centre was a Simplex five-way double fuse distribution board, from which the sample circuits were run to various lamps, showing the surface method of wiring. Other fittings, etc., were also shown.

Mr. Washington-Hume had on show a half-size working model of a patent automatic signalling apparatus worked by the locomotives and capable of indicating to any signal-box or station the distinguishing number of any approaching train, even if late or out of its order, and also a means of signalling to the trains from the signal-boxes or stations.

The models exhibited by Messrs. Babcock and Wilcox, Limited, naturally included one representing the well-known water-tube steam boilers, for which the firm are noted. The model was on the scale of one-eighth of the ordinary size, but was complete in every particular. A model superheater was also exhibited.

Messrs. Crossley Bros. had on exhibition two of their latest types of gas-engines, one of the "S" type, giving 19 actual horse-power as a constant working load, and the other, of the O. E. type, arranged for driving a dynamo. That it is well suited to this work was shown in actual practice on the stall, some arc lamps being lighted by it without the aid of accumulators. An oil-engine of the low-tension type, and giving 2½ h.p. as a constant working load, was also on view.

Messrs. John Gibbs and Son, of Liverpool, had on exhibition a number of ventilating specialities, including their patent electrically-driven fans.

The dry-seat question on tramcars received considerable attention at this exhibition, and a large exhibition of ever-dry seats was shown. These seats were good, bad, and indifferent, the last two classes predominating. Some which were expected to stand the rough work of an ordinary tramcar could not even stand examination at the exhibition, and, although working properly on the opening day, on the third or fourth day of the exhibition were total wrecks. Most of the seats in their alternative position to secure dryness were so uncomfortable that one would rather use the seat without the dry-seat device. Some of the dry seats required careful handling, or a pat in the back from the back part or a sudden turning over of the seat awaited a passenger. Amongst them, however, were some which were noteworthy. The first prize in the competition was obtained for the new London seat (Peter Burns). This seat is automatic in its action. When the sitter rises the seat by natural action reverses, so that the sitting surface is kept dry, and it is only necessary to reverse the seat to procure a perfectly dry sitting surface. Another very good seat was the "Everdry," made by Mr. P. W. Bramwell, Leeds, and which is being introduced on the Sheffield and the Leeds tramways. It consists of a flexible cover laced over a system of rollers which are carried in a casing attached to the underpart of the seat. This cover can be drawn out at either side, if necessary, and laid over the seat, and will on being released automatically glide back into its place. Thus it will be seen that a dry cover is always awaiting the next passenger, independent of any consideration on the part of previous passengers.

There was also a comparatively new compound made of cedar wood and graphite, termed Dixon's graphited wood-grease, for the prevention of wear of gear and of noise, and which is made by the Joseph Dixon Crucible Company, of Victoria-street.

The Mossberg Roller Bearings Company had a good show and also the Granville type, a machine remarkable for a number of important improvements.

Amongst other exhibits were the Albion Clay Company, Limited, conduits and troughing (Sykes's patent); Messrs. Doulton and Co., Limited, who exhibited conduits, stoneware troughs, insulators, crucibles, water softeners, and tiles. A gas-engine was to be seen working at the stand of Messrs. Tangyes, Limited, and also an oil-engine (Pinkey's patent), a vertical steam-engine, and lifting tackle. There was also shown a serviceable portable hydraulic wheel press tested to 50 tons, for putting on and taking off one railway wagon or tramcar wheel at a time, taking solid wheels up to 27in. diameter and spoke wheels up to 36in. diameter. A hydraulic rail bender, manufactured by this firm, was also exhibited. The Electric Tramway Equipment Company, of Birmingham, had various types of insulators on show. A sample of flexible bracket arm suspension was exhibited, by the use of which the same flexibility can be obtained from bracket arms as from the span wire construction. Messrs. S. Z. de Ferranti, Limited, showed photographs of engines, dynamos, and switching gear. Messrs. Henry Pooley and Sons, Limited, exhibited, amongst other things, an enormous weighbridge. Messrs. Witting Bros. (Electricité et Hydraulique) had a good show of motors, trucks, car fittings, motor-generator, switchboard, and cables. The Worthington Pumping Engine Company showed pumps, heaters, and condensers. Examples of roller bearings were exhibited by the Roller Bearings Company, Limited; and at last the "Perfection" system of patent glazing by Messrs. Helliwell and Co., Limited, of Brighouse.

In connection with the exhibition a very well-got-up booklet on "Tramway Statistics," containing a number of useful tables, giving particulars of electrical, steam, and horse tramways, was distributed by the Ocean Accident and Guarantee Corporation, Limited. Amongst their various policies we noticed especially the "advanced" policy against accident, illness or permanent incapacity, and the third-party indemnity for drivers.

THE POWER BILLS.

The Select Committee of the House of Commons met again on Wednesday, July 4, to consider the South Wales

Digitized by Google

Electrical Power Distribution Bill. Those engaged in the case were supplied with a clause governing the conditions of supply which was drawn by the Board of Trade, and Mr. PEMBER, Q.C., for the promoters, asked if this clause might be taken as embodying the declaration made by the chairman on the previous day.

The CHAIRMAN replied that in principle it did, but the clause might be subject to detailed alterations.

The clause read as follows :

"1. Electricity shall be supplied under this Act only for use for the purpose of providing power and for the lighting by any person to whom it is so supplied for power of any premises in any part of which the power is utilised, and of any houses usually occupied by persons employed on those premises.

"2. Electricity shall not be supplied under this Act by the company in any area being at the passing of this Act the area of supply of any authorised distributors except with the consent of those distributors, but that consent shall not be unreasonably withheld. If any question arises whether that consent is unreasonably withheld or not that question shall be determined by the Board of Trade. The consent shall be deemed to be unreasonably withheld if the authorised distributors are not willing and in a position to give the requisite supply upon reasonable terms and within a reasonable time, and in considering what are reasonable terms and what is a reasonable time the Board of Trade shall have regard to the terms upon which and the time within which the company are willing and in a position to give the supply.

"3. If at any time after the passing of this Act any local authority or company become authorised distributors in any area within the area of supply under this Act, those distributors shall, subject to any provision to the contrary in the Act or provisional order under which they become so authorised, have the option to take over any supply then given by the company for use exclusively within the area of supply of the distributors upon the terms and subjects to the conditions provided in the Act or order."

The term "authorised distributors" was stated to mean any local authority, company, body, or person authorised by Act of Parliament or provisional order confirmed by Parliament to supply electricity within the area of supply.

Mr. PEMBER asked the committee to consider the advisability of making certain alterations in the clause. He pointed out that the persons, companies, or bodies who were to have the power to provide electricity were not to be prohibited from using it for their own purposes of lighting. He therefore told the committee that under the clause there was imminent danger of a state of things arising which might render the Bill useless. A great deal of his electricity could be supplied by private wayleaves. He knew no reason why, if he could supply the great number of consumers he proposed to supply, he should not be allowed to do it if the common law of the kingdom allowed him to do it, and if compulsory powers were given for generating and supplying electricity. If he were prohibited from doing that, his Bill might become useless. He reminded the committee that the term "authorised distributors" was expressly made to include the company. The effect of the third section of the clause would be that as soon as any local authority found the company was distributing energy to their own advantage, all they had got to do was to get a provisional order or an Act, and then they were entitled to buy the company up at any moment they pleased. The company ought to have a free hand to supply electricity to whomsoever they could bring it by private arrangement.

Mr. H. LLOYD, on behalf of the local authorities of Cardiff, Swansea, Newport, and Barry, complained that in the clause drafted by the Board of Trade there appeared to be no sort of definition of power. His contention was that local authorities which were ready and willing to obtain powers should be placed in as good a position as the others. Barry was not so authorised, and Barry ought to be placed on the same level as Newport, Swansea, and Cardiff.

Mr. MEAGER addressed the committee on behalf of Neath, repeating the contention of Mr. H. Lloyd that no distinction ought to be made between local authorities which had obtained powers of supply and those which had not.

The committee then considered their decision on the clause in private.

After a long deliberation, the CHAIRMAN announced several alterations in the phrasing of the clause. In the first section of the clause the sentence now read : "Electricity shall be supplied under this Act only (*a*) for a supply in bulk to authorised distributors, and (*b*) for the purpose of providing power," etc. In the second section the alteration was, with regard to the willingness or unwillingness of authorised distributors to give a requisite supply on reasonable terms and within a reasonable time, the Board of Trade should, "amongst other things," have regard to the terms on which the company were willing and in a position to give the supply. The third section as altered read as follows : "If at any time after the passing of this Act any local authority or company become authorised distributors in any area within the area of supply under this Act, the company shall be subject to any provisions which may be made by the Act or provisional order under which the distributors become authorised as to the taking over of any supply then given by the company for use exclusively within the area of supply of the distributors."

The committee also added a fourth and a fifth section to the clause. The fourth ran : "Nothing herein contained shall prevent the company from applying for provisional orders under the Electric Lighting Acts of 1882 and 1888." The fifth clause was : "Nothing in this section shall authorise the company to supply electricity for lighting other than the lighting specially mentioned in this section."

The committee then adjourned till Thursday.

THURSDAY.

On Thursday Mr. H. LLOYD, representing Barry, asked the committee to revise Sub-Section 2 of the clause which had been drafted the day before. The clause read : "Electricity shall not be supplied under this Act by the company in any area being at the passing of this Act the area of supply of any authorised distributors except with the consent of those distributors, but that consent shall not be unreasonably withheld." He desired that the words, "nor shall distributing mains be laid," should be inserted after the phrase, "electricity shall not be supplied," explaining that the local authority he represented objected to the power given under the clause to the company to break up streets and lay their distributing mains.

The committee, however, declined to insert the words.

Mr. FITZGERALD raised the question whether three or seven years was a reasonable time within which the company should give the supply, and also whether 10 or 20 per cent. on the outlay was a reasonable expenditure, and he asked the committee to give a decision on the point.

The CHAIRMAN announced that a clause to be further considered by the committee would be inserted.

Replying to further remarks, the CHAIRMAN said the committee had decided that the dividend payable by the company should be limited to 8 per cent., and that there should be a clause giving the Board of Trade power of revision after 10 years. It was desired that power should be given to introduce a sliding scale if after the experience of 10 years such a change was considered necessary.

The committee then passed to the consideration of the Durham Bill.

Later in the proceedings the committee resolved upon the representations of the counsel to reconsider their decision with regard to the maximum dividend. They deliberated in private for some time, after which it was announced that the committee adhered to their decision, that the dividend should be fixed at 8 per cent. They were also of opinion that a sliding scale should be adopted, the principle of the sliding scale to be 5 per cent. on the main charges, and the raising of the dividend 1 per cent. The Lancashire and Durham schedules as amended were accepted. The standard price for South Wales would be 2½d., and the sliding scale would be subject to revision by the Board of Trade after the experience of 10 years.

The committee then adjourned till Friday.

Digitized by Google

FRIDAY.

On Friday, as to the price for South Wales, Mr. RAM asked that they should be allowed to retain their maximum of 4d. per unit for the first 400 hours. He also asked if, instead of the 5 per cent. reduction under the sliding scale, ¼d. reduction in 1¼d. would not be better.

In the case of the South Durham Bill, Mr. MOON asked that the words "standard dividend so fixed" should be omitted from the dividend clause. He also pointed out that an 8 per cent. maximum cumulative dividend, if subject to revision, was not an 8 per cent. dividend at all, but before it was reached might be greatly cut down by such a body as the Board of Trade. He asked, therefore, that the Board of Trade should not have power to alter the sliding scale, they having plenty of power to protect the public without this.

Mr. FITZGERALD, on behalf of Walker and Wallsend, asked that the clause should not be altered in this way.

Mr. J. SHAW, for the Lancashire Bill, spoke in favour of the alteration.

Mr. MOON then said the Durham Company wanted power to carry their mains overhead, subject to the Board of Trade regulations. The overhead method of carrying mains was specially applicable to colliery districts, where ground subsidences might occur and ruin a cable, whereas an overhead line would not be so badly affected.

Mr. W. L. MADGEN, examined by Mr. Moon on the question of the overhead wires, said in his district the roads were narrow and winding lanes. There would be less likelihood of interruption of supply through subsidence of ground if the wires were carried overhead in certain places. He would be willing for the Board of Trade to say whether in any case the overhead wires should be carried over a road.

In reply to the chairman, Mr. MADGEN said Brandon was a good specimen of the place to which they wished to convey electricity by overhead wires.

The question of the cessor clause was then discussed, the clause stating that if within one year from the passing of the Act the company have not substantially commenced their works for the purpose of carrying out their powers under this Act, and if within three years after the date of the passing of this Act the company have not erected a generating station or stations sufficient in the opinion of the Board of Trade, and are not in a position to supply therefrom, the Board of Trade may order that the powers of the company under this clause shall cease, and on any such order being made these powers shall cease accordingly. After a lengthy discussion between the counsel on this clause the committee-room was cleared, and on being called in the parties were informed that the committee's decision on the South Wales Bill was that the dividend be not subject to revision. The relation between price and dividend would stand.

As to the overhead wires in the Durham district the urban authorities would have absolute veto, and rural authorities only a qualified veto. In the cessor clause two years and four years to be substituted for one year and three years.

As to the South Wales Bill the maximum price would be reduced from 4d. to 3d. In the Lancashire Bill the nature of the cable would be subject to the Board of Trade only. The committee then adjourned till Monday.

MONDAY.

On Monday the smaller clauses of the Bills were agreed to, and the measures were ordered to be reported to the House for third reading.

CHELSEA TRAMWAY SCHEMES.

The following report of Mr. T. W. E. Higgens, A.M.I C.E., surveyor to the Vestry, has been presented to the Works Committee:

"In considering the advisability of giving their assent to any tramway scheme affecting Chelsea, I desire to draw the very serious attention of the committee to an aspect of the question which too often is overlooked. Such considerations as to whether one particular route in Chelsea is superior to another, or whether the introduction of tramways into business streets is detrimental to trade, should no doubt receive attention, but the question which I wish to raise is a fundamental one—namely, is it to the benefit of the public at the present stage of progress and civilisation that any road authority in a large city should permit a tramway to be laid?

"The whole object of a tramway is to transport a certain number of persons from one place to another. This could be done by any vehicle, but the necessity for providing for the transport of large numbers of passengers arose some years ago in the suburbs, and was at that time best met by the construction of tramways, which have thus usually first been laid on the outskirts of towns, where the road surface was indifferent, and consequently the traction was difficult to ordinary vehicles, the lines of tramrails being sunk in the streets to improve the traction for the tramcars only. Or, to put it simply, the surface of the roadway for ordinary traffic was rendered more uneven and more difficult of traction in order that the vehicles belonging to some special owner should have special facilities of traction. The whole question is one of traction. And the Vestry has to face this position: if it consents to tramrails being laid in King's-road, it will consent to the traction for ordinary vehicles being made more difficult, without, I submit, improving the traction for the tramcars.

"It has been found by experiments that the tractive resistances of various surfaces on the level are as follows: asphalte, from 15lb. to 30lb. per ton; tramrails, from 15lb. to 40lb. per ton; macadam, from 45lb. to 60lb. per ton. If, therefore, tramrails were laid in the King's-road asphalte, the traction would be no better for the trams, but very much worse for the ordinary traffic and the cyclist, who would find the hollow of the rails spoil the road surface.

"Of late years, however, tramways have had an excuse for their existence. Electricity has been largely used in working them, and this motive power is suggested for the proposed scheme. So long as the perverseness of the British Legislature threw obstacles in the way of mechanical traction on ordinary roads, so long had the electric tramways an excuse. But for the last three years they have had none. Given a good smooth surface, the mechanically-propelled cars can travel as easily as the trams, can be turned in and out of the traffic, will offer no obstruction to other vehicles, will require no unsightly overhead wires or dangerous slots in the road, and will transport their passengers as conveniently and speedily as the old-fashioned trams on rails.

"I therefore do not hesitate to say that at the present time, when mechanical traction is making such advances, and can only continue to do so as enlightened public Boards provide perfectly smooth road surfaces, no scheme which proposes to provide an inferior road surface when a better one is known should receive the approval of a local authority; and as every tramway scheme does this in a large city, I feel that it is not now to the benefit of the public that tramrails should be laid in this part of London.

"The London County Council, in their letter, say that a sum of £50,000 would be spent in paving works, exclusive of laying down and paving the tram track. The cost of an overhead trolley system double track would be about £10,000 per mile, and a conduit system probably £15,000 per mile, so that for the two miles from Putney to Battersea Bridge they would spend on road surface and tram track some £60,000 to £80,000, about one-half of which would be spent in rendering the traction on the road surface more difficult for the ordinary vehicle.

"If the County Council would pause before throwing away millions of pounds in tramway work, and bring forward some scheme for widening and improving our main thoroughfares, and laying therein perfectly smooth pavements, over the whole surface of which the tractive force required to draw a vehicle could be reduced to the very smallest amount possible, and would establish thereon a suitable system of mechanically-propelled vehicles, the public who ride, the tradesmen along these routes, the cyclists, and the owners of all vehicles would be gainers, and the money spent would be laid out for the benefit of all, and not of one particular class of traffic."

CHELSEA—LONDON COUNTY COUNCIL AND TRAMWAYS.

The report of Mr. T. W. Higgens, the able surveyor to the Chelsea Vestry, will cause a flutter in the dovecotes of the London County Council. He gives certain reasons why the various authorities should not blindly accept the wild-cat schemes emanating from that body. The fact is, these half-ignorant, half-socialistic bodies merely look at the surface of things, and promote schemes that tend to notoriety and the immediate acquisition of votes. It has long held as axiomatic that a gift horse should not have his mouth looked at, and so these promoters of municipal tramways hope to obtain votes because of profits in aid of the rates. Practically, Mr. Higgens adopts the views we have so often urged, and we have evidence that converts are increasing in number and in influence. In the first place, we have somewhat reluctantly accepted the inevitable—that tramways will be largely used during the transition period between the killing-off of animal traction and the complete adoption of mechanical traction. Tramways are at the best but a temporary expedient, and their use will set back the time of adoption of a more perfect system, at the same time rendering the perfect system far more difficult to introduce. If anyone not fully conversant with the particular phase of the topic introduced by Mr. Higgens needs an object lesson upon the influence of tramways upon the condition and upkeep of streets, let him watch the Camberwell New-road for half a year. It will be seen that the report referred to takes into consideration the necessities of what may be termed suburban districts and of main streets. The condition of the roads outside the principal business and residential areas, and the necessity for expediting the passenger traffic between the business and residential areas, have necessitated the use of tramways, principally because the suburban street surfaces were not so good as they ought to be. That seems to be the crux of the whole matter. So far as the municipal authority is concerned, its duty is to render the whole street surface as perfect as possible for the use of all classes of traffic. The introduction of tramrails in order to make the running of special vehicles more easy, is an acknowledgment that the whole surface of the street is not what it should be. We presume that, on first principles, there is no objection to the improved running surface which is given by tramrails being provided for the benefit of a certain class, provided that there is no extra cost to the non-user, and that the rest of the street surface is not made worse. The first of these conditions applies; but, as everyone knows, the second condition is never obtained. A good street surface and tramways are mutually destructive. Again, while ordinarily there is no income derived from the use of the streets by the general community, this use represents an exceedingly valuable right to the inhabitants of the town. People are apt to forget that the unjust profits which the London County Council expect to take from the users of their tramways, and to apply to the reduction of rates, may be small in amount compared with the

Digitized by Google

monetary loss sustained by the general public in consequence of the interruption to vehicular traffic caused by the tramcars, together with the extra cost of conducting this traffic over the bad road surfaces which are inevitable when tramlines are laid in a busy street. The following paragraph in Mr. Higgens's report is worthy of most careful attention: "I therefore do not hesitate to say that at the present time, when mechanical traction is making such advances, and can only continue to do so as enlightened public Boards provide perfectly smooth road surfaces, no scheme which proposes to provide an inferior road surface when a better one is known should receive the approval of a local authority; and as every tramway scheme does this *in a large city*, I feel that it is not now to the benefit of the public that tramrails should be laid in this part of London." We particularly call attention to the four words, "In a large city," and suggest that all authorities controlling the streets should consider how far the statement in this report applies. Undoubtedly, the era of purely mechanical traction should be hurried on as fast as possible, as such a system would, if that must be the ruling point, confer a far greater aid to the saving of rates than the modicum to be obtained by the introduction of tramways under the auspices of either the London County Council or other local authorities.

OBITUARY.

The Late Mr. E. C. Short.

We regret very much to have to record the death of Mr. E. C. Short while on active service with the Electrical Engineers (Royal Engineers) Volunteers in South Africa.

THE LATE MR. E. C. SHORT, A.I.E.E.

His death, which was caused by enteric fever, took place at Kroonstadt on the 25th ult. Mr. Short was one of the original members of our Electrical Engineers Corps, and was again to the front when volunteers were asked for to proceed to South Africa. He left England for the war on March 16, and proceeded up country with his corps from Cape Town on April 17. Their first work was in connection with an important bridge at Bethulie, where a searchlight and six arc lamps were employed. On May 5 his company moved to Bloemfontein, and we fear that it was at this place that Mr. E. C. Short contracted the fever which ultimately carried him off. His electrical engineering commenced with a course at the University College, where he obtained first class. Mr. Short was then articled to the firm of Messrs. Crompton and Co., and from their employ passed on to the Willesden works of the Metropolitan Electric Supply Company, where he was an assistant engineer. While we are proud to have our young electrical engineers in the forefront of our country's wars, we grieve for the heavy toll taken of them. Our deepest sympathies are extended to the parents and relatives of Mr. Short, who was only 25 at the time of his death.

The Late Senor Don Francisco de Paula Vasquez.

We regret to report the death of Senor Don Francisco de Paula Vasquez, who died at Madrid on the 24th of last month after a comparatively short illness. Mr. Vasquez, who was only 61 years of age, had been a high official in the Cuerpo de Telegrafos, and was honorary local secretary in Madrid to the Institution of Electrical Engineers, as well as agent for the Spanish National Telegraph Company and the South American Cable Company. Many of our readers will have pleasant recollections of meeting Senor Vasquez at the telegraph conference at Paris, where his kindly humour and sympathetic manner gained for him many English friends, who we are sure will join us in expressing our condolences with his family and with his many friends in Spain.

ELECTRIC LIGHTING AT WILLESDEN.

We are pleased to announce the fact that an extensive scheme for electric lighting and traction in the Willesden district is likely to be accepted in the course of a week or so. The history of the electric lighting and tramway undertaking in this district was recently given to us by Mr. E T. Ruthven Murray, M.I.E E, the electrical engineer to the Council. In the early days some consulting engineers' reports were obtained, and a small committee was then organised to travel round the country and inspect a number of electric light stations. Amongst other places visited was Worcester, where the committee found Mr. Ruthven Murray in charge. The information he gave them was considered so very useful that he was asked to give his opinion on numerous other points that occurred to the committee when making up their final report. The Willesden District Council, after the consideration of this report, decided to advertise for an engineer who should be capable of undertaking the design of the station, and also have charge of it when erected. A large number of applications were received, and Mr. Ruthven Murray was duly appointed to the position. We believe that it is now some 18 months since he took up his duties, and that the delay in commencing work has been due to financial reasons connected with some other department of the Urban District Council. As a result Mr. Ruthven Murray has had ample time to work out his scheme of distribution, and to design the electric light station and tramway scheme.

In his report, which is dated April this year, Mr. Murray fully describes his scheme. He divides Willesden into three districts which are approximately equal in area, each containing about 2⅓ square miles. In the one section the electricity works will be placed, and transforming and accumulator sub-stations will be erected in each of the other districts. The distribution from the main generating station to the sub-stations will be carried out by means of the three-phase current at 3,000 volts pressure. In the sub-stations this will be converted into continuous current by means of motor generators. The distribution will be on the three-wire system, with 480 volts between the outer conductors and 240 volts at the consumer's terminals. The tramways will be supplied at 500 volts. Before proceeding on Mr. Murray's report, the Council obtained an opinion on the same from Mr. E. Manville, M.I.C.E., of the firm of Messrs. Kincaid, Waller, and Manville. Mr. Manville's report is dated June 18, and in it he expresses his opinion that the district is a particularly valuable one from an electrical undertaker's point of view. Mr. Manville concurs on the whole with Mr. Murray's suggestion as to the scheme to be

Digitized by Google

adopted, but advocates a drawing-in system for the feeders instead of laying them on the solid system. He also advocates increasing the amount of distributing mains to be laid in the first instance. In the conclusion of his report, Mr. Manville states his appreciation of the careful and thorough way in which Mr. Murray has thought out the details of the scheme. He adds that the scheme is a good one, and that with a district such as Willesden the prosperity of the undertaking is assured.

This report of Mr. Manville's, together with a supplementary report by Mr. Ruthven Murray, has been unanimously approved by the Electricity Committee of the Willesden District Council. It has also been before the Council, but at Mr. Murray's request it was not voted on until his supplementary report had been printed and circulated. The estimates in the new report arrange for an expenditure of £143,600 on behalf of the electric lighting section of the works, while in connection with the tramways a further expenditure of over £53,000 is advised in the first instance. Seeing that the population of the district is now nearly 120,000, and that it has practically doubled itself in the last 10 years, we are sure that the expenditure of £200,000 is warranted. We wish success both to Mr. Ruthven Murray and the Urban District Council in their joint endeavours to increase the healthiness of the district of Willesden.

THE PARIS EXHIBITION.

[BY OUR OWN CORRESPONDENT.]

(Continued from page 872, Vol. XXV.)

Before passing on to the other machines on view, a few words as to the general system of supply in the Exhibition may not be out of place. The executive engineers decided in the early stages to give a considerable bonus to those makers of engines and dynamos who would exhibit machines and supply load from them for the Exhibition purposes. They supplemented this with a sum per kilowatt delivered, which in the case of the engines will quite pay the cost of the oil, and even allow a slight margin for liquidating the engine attendants. This latter sum was not sufficient to make the makers very keen in completing their contract, and, due to the bungling on the part of the Exhibition authorities, the building to contain this plant was about the last to be finished. This left very little time for the putting up of the plant, and has driven a large number of exhibitors on to the mains of the various supply companies of Paris. Underneath the Château d'Eau are placed two large switchboards, on which is received the current generated by the various machines in the Exhibition. On the switchboard devoted to direct currents all arrangements have been made for working the machines in parallel, and this is done with more or less success. In the case of the alternating currents, however, owing to difficulties in synchronising, and in certain instances to slight variations in the frequency, no attempt at parallel running has been made. Instead of this, each of the large circuits is brought to one panel of the alternating-current switchboard, on which switches are provided so that it can be quickly thrown on to either of the two large alternators. In this way the risk of breakdown is, to a certain extent, avoided at the expense, of course, of providing a poor load factor for each machine, and a slight flicker in the lights which will be noticed when the load is switched over. As the circuits take a considerable amount of current, the throw over will also be a trial of the governing properties of the various sets. The full description of the distributing system of mains running from the switchboard I propose to defer until a later date, but I wish to get into print quickly my condemnation of the system of fuses adopted by the authorities. These fuses have already caused a fire, and it will not be surprising if numerous other fires take place before the Exhibition closes. The mains convey the direct current on the three-wire system, with 500 volts between the extreme wires near the machine, and 440 volts where the supply is given to the stall-holders. They are placed underneath the floor of the Exhibition, which is of wood, laid on wooden joists. Under the side and main gangways fuse boxes are constructed by the simple process of placing a wood base on the bare soil underneath the floor. These wood bases have clamps to embrace the cables, and there are attached to these clamps lead fuses, which are taken to the branches going to the stall-holders. The three poles of the three-wire system are all mounted on the same base-plate, and are all divided from one another by a thin wooden partition, which is, of course, exceedingly likely to ignite when a fuse goes. Over the whole of the fuses a cover of wood is placed, which will also serve to help to conduct a fire as occasion serves. As these wood cases come close in to the joist in the floor, it will be seen that the electrical engineers advising the Exhibition authorities on the laying-out of their electrical system have great faith in the non-inflammability of wood. The wood covers to the fuse boxes will certainly protect the fuses for a little while against a flow of water from above, but here, again, the work is of such a light description that it cannot be looked upon as a reasonable safeguard from the water rising from the subsoil. Any water escaping from the circulating pipes for the condensers and passing over the soil below the floor would, of course, be fatal to the insulation of these fuse blocks.

View of the Esplanade des Invalides.

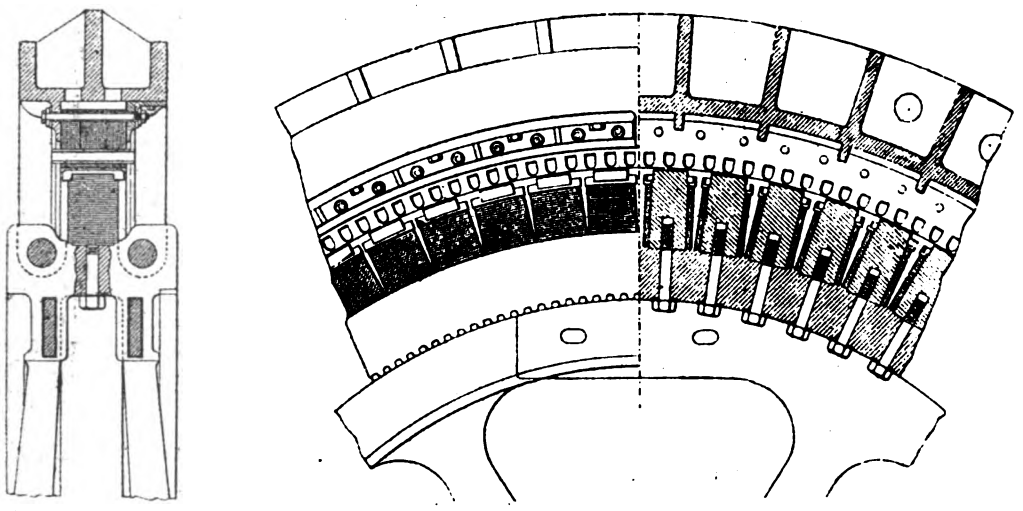
One of the most interesting machines in the Paris Exhibition is to be seen at the stall of Mr. Alexander Grammont This firm exhibit a large alternator of 600 kw., the general design of which can be gathered from the section and elevation (Figs. 1 and 2). The frequency of this machine is 50, and it has 64 poles. The voltage of the machine is 2,400. The armature is wound for three-phase work on the star system, with 1,390 volts in each limb. The following particulars of the machine may be of interest. The total excitation in ampere-turns is 9,610, of which 7,550 are required for the air gap, 180 for the armature iron between the poles, 120 for the armature iron behind the poles, and 1,660 for the field-magnet poles. It is estimated that in the yoke some 98 ampere-turns are required. The number of wires in each hole in the armature core is 70. The armature reaction for cos $\phi = 1$ is 2,020. Some 17½ kw. are required for excitation. The following are the calculations for the efficiency of the machine:

	Cos $\phi = 1$.	Cos $\phi = 0{\cdot}7$.
C^2R losses in the field-magnet coils ...	4,250	11,500
C^2R losses in the armature	6,210	12,700
Hysteresis	14,050	14,050
Mechanical losses	6,000	6,000
Total loss in watts	30,510	44,050
Efficiency per cent.	95	93·2

The most interesting point, however, about the exhibit is the compound exciter, which provides automatically the correct exciting current to give constant voltage at all loads, independent of the power factor which the load may have. This compound exciter was designed by Messrs. Hutin and Leblanc. It consists in principle of an ordinary armature of a continuous-current machine (Fig. 3) which

Digitized by Google

is subjected to the influence of two revolving magnetic fields created by the two systems of iron cores and windings, marked B and C respectively. The winding on the



FIGS. 1 AND 2.—Section and Elevation of the Grammont Alternator.

core B consists of fine wire, and is connected across the terminals of the alternator as a shunt. The winding on the core C is connected in the main circuit from the alternator, thus carrying the current from the alternator. The characteristic feature of the invention is that by the special and ingenious arrangement of the inventors it is possible to receive a continuous current from the machine, although

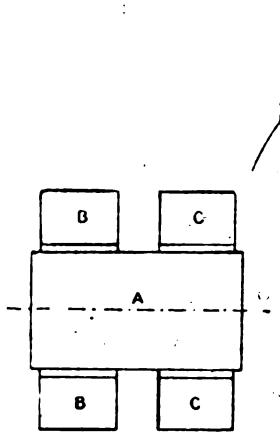


FIG. 3.

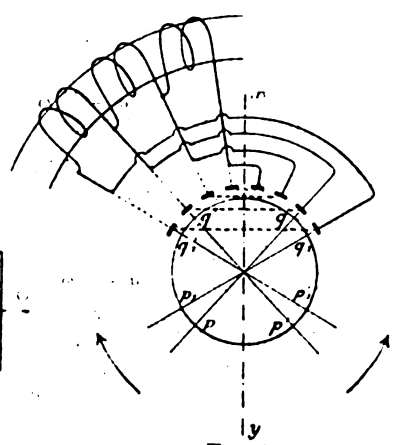

FIG. 4.

the brushes are fixed and the current is induced by a revolving field. In order to complete the description, it is well to describe the machine in detail. The winding on the armature corresponds in every respect to that of an ordinary continuous-current machine which utilises N lines of brushes and has N poles, but from the armature to the commutator all the connections are the reverse of the usual

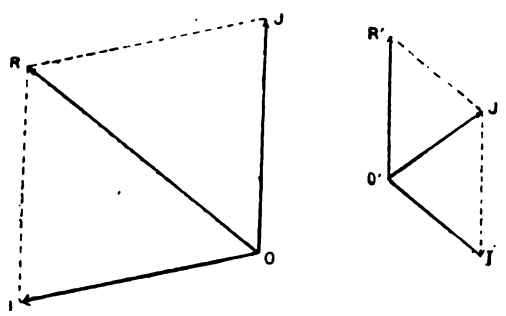

FIG. 5.

ones with N symmetrical poles. Thus in this case the number of sets of brushes need not be equal to the number of lines of poles. One or other of these conditions will suffice, as we shall show further on, to obtain the desired result, but their combination facilitates in practice the construction of the machine. If we call N the number of lines of poles due to the revolving field; K the number of lines of brushes; a the frequency of the alternating current in the field-magnet system; and ω the speed of the armature, we can then ascertain what the necessary conditions are in order to make the current continuous by the aid of fixed brushes.

This will be $$N + K = \frac{a}{\omega},$$

or, $$N - K = \frac{a}{\omega},$$

according to whether the armature turns in the same direction as the field or in an inverse direction. As N and K are determined by the construction, and are invariable, this condition fixes the ratio between the speed of the exciter and that of the alternator. To explain the working of this machine, let us consider in the first place an ordinary bipolar continuous-current dynamo. Its working only depends on the relative movements of the armature with respect to the field magnet. One is able thus to assume that if one gave to the field magnet an angular speed equal to that of the armature, and in the opposite direction, the armature could be stationary if the brushes were attached to the revolving field.

Let us now consider (1) to reverse the direction of rotation, what is it necessary to do with the brushes, with respect to the armature, to obtain a constant current; (2) how to vary the speed of these brushes. Then, after establishing the general formulæ which give the speed of these brushes, we will find out on what conditions we can obtain their being fixed.

I. *Reversing the Direction of Rotation in Connection with the Armature, the Speed of the Brushes remaining constant.*—Let us refer to our former considerations. We have deduced directly from an ordinary dynamo a theoretical dynamo with fixed armature, and with revolving magnets and brushes. We will suppose, for the present, that our machine is bipolar. If the magnets make a revolutions per second, the brushes will have to accomplish during the same time a revolutions round the collector. Let us imagine diagrammatically (see Fig. 4) a bipolar Gramme ring and its commutator. Let us see at a given moment, p^1, q^2, the position of the line of brushes which would correspond to ordinary connections between the armature and the collector. Let us consider any fixed diameter, $x\,y$, with respect to the collector, and we will suppose, as we have said, that the connections are reversed with respect to this diameter. In our diagram the ordinary connections are indicated by broken lines, and the actual connections by full lines. To the position $p^1\,q^1$ will evidently correspond the position $p\,q$, which are symmetrical with respect to $x\,y$. It follows, in consequence, that if $p^1\,q^1$ become $p_1{}^1\,q_1{}^1$, then p and q will come to $p_1\,q_1$ if the wires are displaced through the same angles, but in the inverse direction. For a machine of n lines of poles we evidently obtain the same result by adopting n symmetrical diameters.

II. *Variation of the Brush Speed.*—Let us consider an armature of n poles fixed in position. With a collector of

Digitized by Google

n lines of brushes these will have to revolve in the same direction as the inducing field and with the speed of this

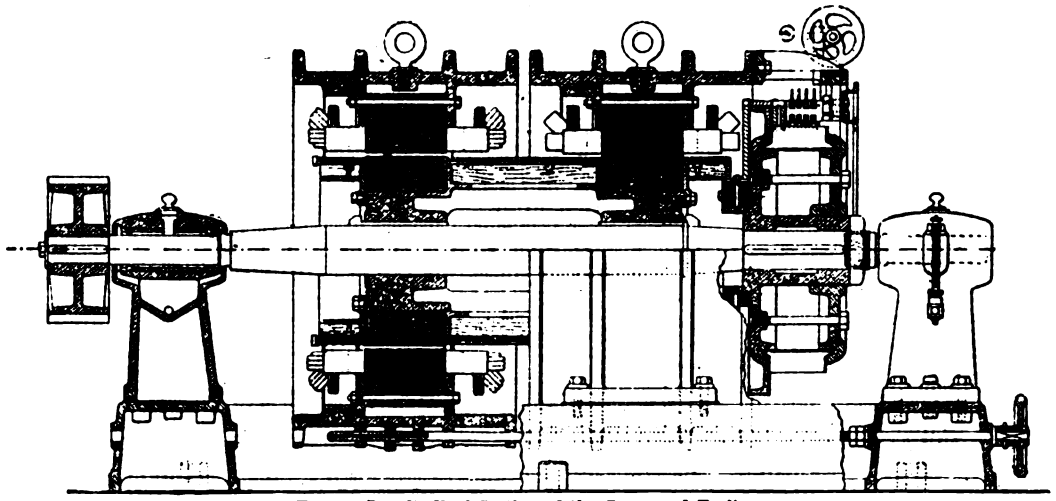

FIG. 6.—Longitudinal Section of the Compound Exciter.

field. But as we admit (theoretically, at least) that the brushes can be independently revolved, we can at will avail ourselves of their speed in modifying the number of

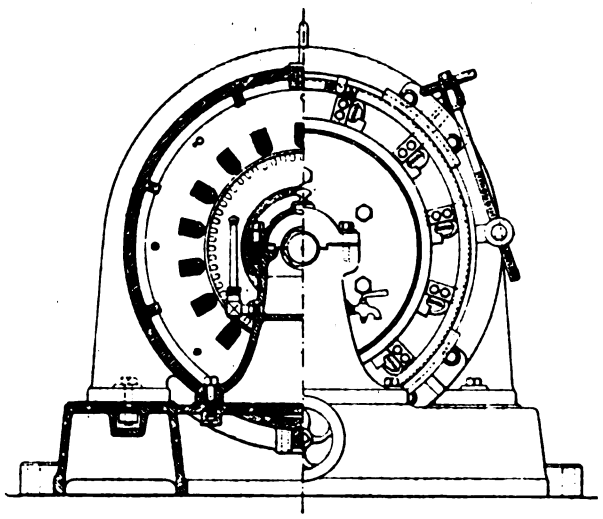

FIG. 7.—Section and End Elevation.

segments of the collector which are in parallel. In allowing only a number n times smaller to remain, it is evident that the speed of the brushes must be n times larger than that of the field, and for k lines of brushes this speed will become equal to that of the field multiplied by the ratio, $\frac{n}{k}$.

The application of these two principles to the compound exciter is as follows: Let us consider, in the first place, one of the two stators which envelope the armature. We will call N the number of its lines of poles, and a the frequency of the exciting current. The speed of the revolving field will evidently be $\frac{a}{N}$. Let us suppose that the armature revolves in the same direction with the speed ω; the relative speed of the field with respect to the armature will be $\frac{a}{N} - \omega$. The multipolar armature will also have N poles. For k lines of brushes to the collector, the speed of these poles will be, as we have shown:

$$\frac{N}{k}\left(\frac{a}{N} - \omega\right),$$

or,

$$\frac{a - N\omega}{k}.$$

The armature being attached to the ordinary commutator by a special reversing connection, the direction of this rotation will be reverse to that of the armature.

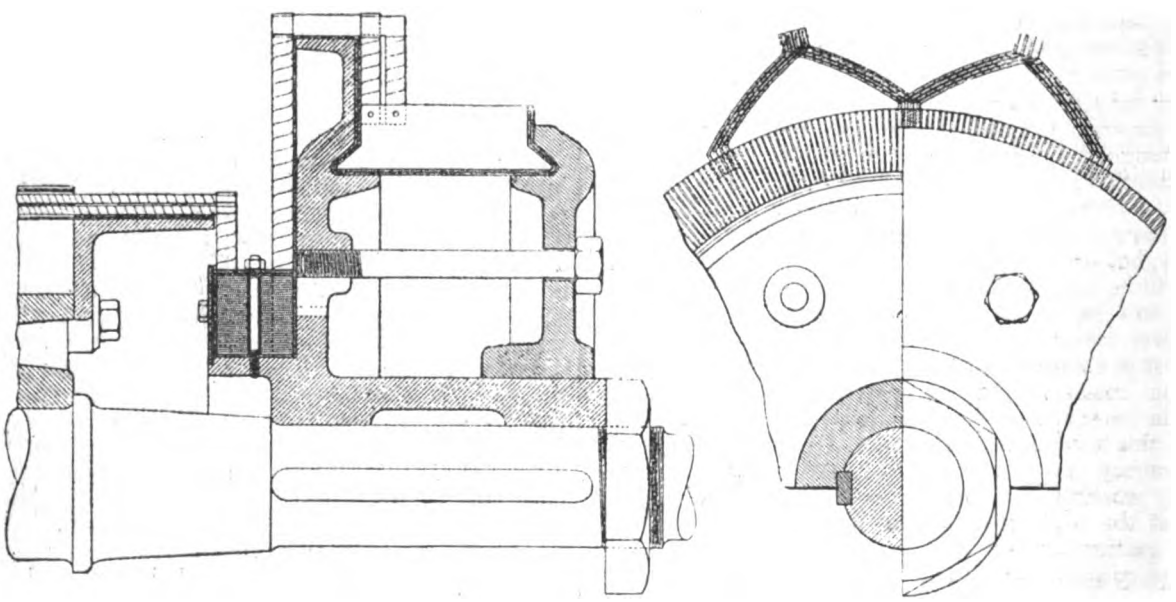
The absolute speed of the brushes in space is therefore

$$\frac{a - N\omega}{k} - \omega.$$

To obtain fixed brushes, one must revert to the first condition—viz.:

$$N + k = \frac{a}{\omega}.$$

We should obtain a different solution to the problem in causing the armature to revolve in a contrary direction to that of the field. The relative speed is then $\frac{a}{N} + \omega$. The brush speed, for k lines of brushes,



FIGS. 8 AND 9.—Details of Commutator and Connections.

Digitized by Google

$$\frac{N}{k}\left(\frac{a}{\omega}+\omega\right), \quad \text{or,} \quad \frac{a+N\omega}{k}$$

in the direction of the field. It is useless in this case to use the special connections, the absolute brush speed being

$$\frac{a+N\omega}{k}-\omega.$$

The condition of their being fixed

$$k-N=\frac{a}{\omega}.$$

The arrangements just described allow us to collect, with fixed brushes, the continuous current induced by a revolving field. We immediately conceive the possibility of arriving at compounding conditions, using, as we have previously said, for the excitation of the exciter, two distinct stators, one of them connected as a shunt to the alternator terminals and the other in series with the armature circuit. We only have now to show how it is possible, by correctly placing the two stators with respect to each other, to produce a compounding current both for varying load and lag. The problem is to produce in the exciter a resulting field always having the two following characteristic properties: first, intensity in proportion to the necessary magnetising current, and, consequently, variable with the different outputs of the alternator, and, secondly, independence of phase difference. The first condition does away with the regulating rheostat for the alternator field, while the second prevents the necessity of varying the lead of the brushes and makes the exciter quite self-regulating. To simplify the reasoning and make it more clear, we will suppose in what follows that the alternator only possesses two poles, and that the same is the case in the exciter. We will suppose, in addition, that this last consists of a fixed armature, and that the brushes revolve with the inducing field. These hypotheses do not in any way diminish the generality of the reasoning. We will represent by O J (Fig. 5) the vector of the alternator field. Then, on the other side, O I represents the armature reaction. From O J and O I we obtain the resulting flux, O R. It is on the value of O R that will depend the potential difference at the terminal. We have, in the shunt-wound stator, a flux, $O^1 R^1$, proportional to O R, and in the series-wound stator a flux, $O^1 I^1$, proportional to O I. It will always be easy in changing the dimensions of the exciter to arrive at the equality of the two ratios $\frac{O^1 R^1}{O R}$ and $\frac{O^1 I^1}{O I}$. To obtain the resultant action in the exciter from a flux proportional to a magnetic field of the alternator (supposed for the present to be excited in an ordinary manner, and regulated from a constant voltage), it will suffice then to use the two stators in the well-known way: thus the angle $R^1 O^1 I^1 = \pi$ – angle R O I.

If we suppose the two axes of the alternator and the exciter placed end to end, and the two directions, O R and $O R^1$, brought into coincidence, $O J^1$ will place itself on O J.

On the other hand, if O R or O I should advance or recede slightly, $O R^1$ and $O I^1$ would immediately conform to these displacements. There is, therefore, not only a proportionality, but also a synchronism between O J and $O J^1$. The result will be that, taking the above arrangement, the line of brushes will remain fixed in space whatever the current and power factor may be. For the compounding to be correct, it is necessary that the armature coefficient of self-induction remains always proportional to the mutual induction coefficient in connection with the magnet. Though this is not absolutely true in practice, the approximate accuracy that we can obtain is amply sufficient for everyday working. It remains to be shown that, as we stated at the beginning of this article, by the use of suitable gearing between the alternator and exciter, we can limit the speed of this latter so as to maintain it in a constant ratio with that of the alternator. It will suffice for that to go over the preceding hypotheses, which theoretically bring the machine to the type of a continuous-current dynamo with revolving magnets and brushes. The mechanical action of the alternator cog-wheel on the pinion of the exciter would make its armature revolve with the speed ω. The electromagnetic action of the stators on the rotor would produce a field revolving with the speed $\frac{a}{N}$. But as we have $\frac{a}{n} > \omega$, this last action preponderates, and the pinion "drives the wheel." The mechanical work thus restored to the alternator axle will evidently be, to the total electrical work wanted, in the ratio of ω to $\frac{a}{N}$.

Details of Construction.—The armature and the field revolving in the same way, the condition to get fixed brushes is, as we have established, $N+k=\frac{a}{\omega}$. We have taken $N=3$, $k=6$, which brings us (with $a=50$) to $\omega=333$. Fig. 6 shows a longitudinal plan, and Fig. 7 a transversal plan of the exciter. Figs. 8 and 9 show the details of construction of the commutator, which are very simple. We think it advisable to insist on the advantages which the compounding of alternators presents, as much from an economical construction standpoint as from the working advantages, principally for polyphase traction. Already many trials have been made in that direction. MM. Hutin and Leblanc's solution, equally simply and elegant, completely resolves this question.

The above details are from an article by Mr. J. L. Routin in *L'Industrie Electrique*, but I inspected the machine personally, and had it explained to me by M. Maurice Leblanc. As no photograph has come to hand I cannot show a general view of the exciter, but it is placed at one end of the alternator shaft, and is driven from it by a gearing with a ratio of 3 to 2.

(To be continued.)

YARMOUTH ELECTRIC LIGHTING ACCOUNTS.

From the accounts of the Great Yarmouth Corporation electricity works just received, it appears that the total expenditure on capital account to March 31, 1900, amounted to £40,264. 10s. 11d.

LIGHT RAILWAYS.

The Commissioners have submitted to the Board of Trade an order for the construction of a light railway in the county of Warwick, in the urban district of Nuneaton and Chilvers Coton, and the rural district of Atherstone.

The order by the Commissioners authorising the construction by the Great North of Scotland Railway Company of the light railway between Fraserburgh and St. Combs has recently been issued as a parliamentary paper.

Sir Courtenay Boyle recently had before him for confirmation the light railways orders granted by the Commissioners for light railways from Colne to Trawden and from Colne to Nelson and Barrowford, when several verbal alterations were made in the clauses.

The Thornhill District Council have decided to lodge an objection with the Board of Trade to the Spen Valley Light Railways (Extensions) Order, so far as it refers to the future purchase of the undertaking in their district.

There are two rival light railway and electric lighting schemes at Carnarvon, and a committee has been empowered to interview any likely promoters of light railways in the neighbourhood.

The Blackburn Town Council have resolved that the Light Railway Commissioners be requested to confer on the Town Council, by means of the Blackburn, Whalley, and Burnley District Light Railways Order, 1900, authority to construct or contract for the construction of any railway or railways within the borough of Blackburn. The Clayton District Council have formulated a number of objections to this proposed light railway.

The Bridlington Rural District Council have given their consent to the proposed light railway between Driffield and Hornsea.

According to the report of the West Riding Law and Parliamentary Committee, the Wales and Laughton light railway is promoted by a private company, who seek powers to construct light railways from the parish of Wales to Laughton-en-le-Morthen. The gauge is 4ft. 8½in.

Subject to the clause referring to gauge being eliminated, the order for the extension of the line of light railways from Snowdon Station to Beddgelert will be confirmed by the Board of Trade.

At the last meeting of the Southgate Urban District Council the Chairman, in commenting upon the decision of the Light Railway Commissioners not to allow the light railway to proceed further than the Orange Tree, instead of allowing it to be carried through to Finchley, said the scheme was one of those specially meant by the Light Railway Act. It was carried from Edmonton to Southgate right through a district without railway accommodation, and if it had been carried on to Finchley it would have been one of the most useful light railways in the county of Middlesex.

The Board of Trade have recently confirmed the undermentioned light railway orders: Bexhill and St. Leonards Light Railway Order, 1900, authorising the construction of a light railway in the county of Sussex, from Bexhill to St. Leonards; Cheltenham and District Light Railway Order, 1900, authorising the construction of a light railway in the county of Gloucester, from Cheltenham to Cleeve Hill; Cheltenham and District Light Railway (Extension) Order, 1900, authorising the construction of a light railway at Cheltenham, in the county of Gloucester; and the Robertsbridge and Pevensey Light Railway Order, 1900, authorising the construction of a light railway in the county of East Sussex, from Robertsbridge to Pevensey.

An application for an order authorising the construction of the Deanhead light railway, which will traverse the parishes of Stainland-with-Old Lindley, Barkisland, Upper Greetland, Greetland, and Elland, has been referred to the Waterworks Committee of the Morley Town Council, with power to get the necessary clauses inserted in the order for the protection of the Corporation's water-mains.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

LIGHT RAILWAY COMMISSION.

List of Applications made to the Light Railway Commissioners in May, 1900, for Orders Authorising Light Railways.

Questions.

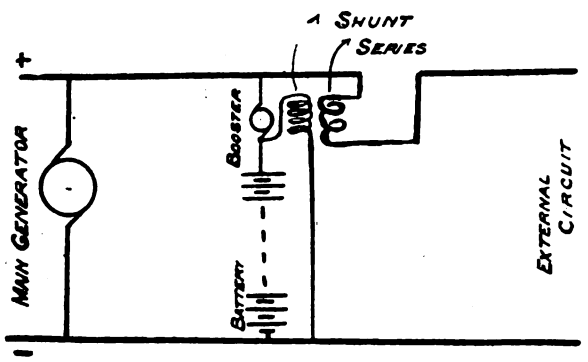
287. Give particulars and explain any arrangement for the abatement of smoke from station chimneys you may have had practical experience with, and state result.—F. R. S.

288. What current density per square inch is it usual to allow in best engineering practice in switch contacts of the following types: (1) laminated contacts constructed of hard-rolled sheet copper; (2) spring contacts in which the contact surfaces are machined, and the only material used is cast brass—*i.e.*, such as those used in the Bates fuse and Brush trigger switch; (3) flat cast-brass machined contacts, which can be held together under considerable pressure by a nut or setscrew. Give sketches.—E. L.

Answers.

Question No. 281.—I have a motor installation working at 100 volts. My engines and generators will only give me 200 e.h.p. The usual power absorbed by the motors is 150 h.p., but at times I shall require 250 h.p. Is it possible to arrange a set of accumulators so as to be charged at light loads, and yet automatically run in parallel with the generators at heavy load? If so, state the arrangements necessary.

Best Answer to No. 281 *(awarded* 10*s.).*—The requirements of the case are met exactly by the ordinary arrangement used in traction stations employing batteries. This arrangement consists in connecting the armature of a special differentially-wound booster in series with the battery across the mains, as shown in the following figure. The object of the booster is to supply the few extra volts necessary to charge the battery when the external circuit is taking less current than the main generators can give, and, on the other hand, when the external circuit requires more current than the normal load of the generators, the booster must give a few volts in the opposite direction and so helping the battery to discharge into the circuit. In order to attain this result quite automatically, the booster field magnets are excited by two distinct windings—a shunt winding connected right across the terminals of the battery, and a series winding carrying the main external current or some definite proportion of it, the rest being shunted past the winding. The two windings oppose one another, the series winding overpowering the shunt to a greater or less extent according to the current in the external circuit.

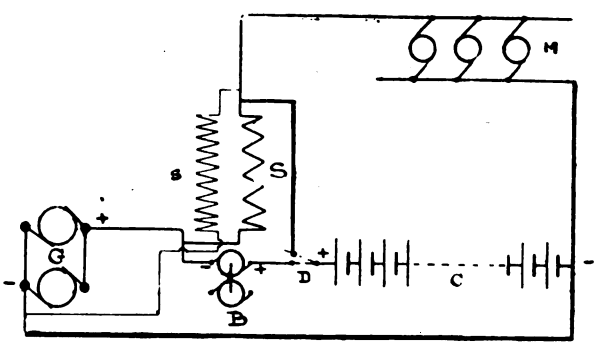


In the case under consideration the circuit voltage is 100, so that the battery should have about 50 cells giving 100 volts on open circuit when fairly fully charged. The voltage required to fully charge these cells will be about 135, and the discharge voltage with the full current of the battery passing will be, say, 85 to 90, allowing for the loss in resistance of battery and connections. The duty of the booster will therefore be: (1) To give 35 volts in a direction tending to charge the battery when the external current is 1,120 amperes—*i.e.*, 150 e.h.p. used in the external circuit. The booster or charging current at this point should be 370 amperes (50 e.h.p.), the two loads together serving to fully load the main generators to 200 e.h.p. (2) To give no volts when the current in the external circuit is 1,500 amperes (200 e.h.p.), the ampere turns given by the series winding on the booster at this current being made exactly equal and opposite to the ampere-turns of the shunt winding when connected across the battery giving 100 volts. (3) To give 10 to 15 volts (in the opposite direction) tending to discharge the battery, when the current in the external circuit reaches 1,870 amperes (250 e.h.p.), the discharge current being 370 amperes.

At intermediate values of the external current the booster voltage would also be intermediate to the above values, thus tending to keep the main generators always working at normal full load (200 e.h.p.), whilst the external load may be anything from from 150 e.h.p. to 250 e.h.p. The capacity of the cells will depend entirely on the relative lengths of time that the external load exceeds and is less than 200 e.h.p. A few trials under ordinary working conditions of load will indicate the correct number of cells to keep in circuit in order that the net result of an average day's work shall be to leave the battery charged to the same extent as at the end as at the beginning of the day. The booster may be driven in any convenient way so long as the speed is fairly steady, though it is usually run by a motor mounted on the same bed-plate.

A booster wound for the above work is naturally more expensive than an ordinary dynamo of the same output, because of the considerably greater amount of field wire necessitated by the differential winding. If the variations in load occur only occasionally during the day and at known times, good results can be obtained with an ordinary shunt-wound booster by means of hand regulation of its exciting current, but such an arrangement is in no way automatic.—Q.

Answer to No. 281 (*awarded* 5*s.*).—Under the conditions specified in the question, a set of accumulators may be arranged in parallel with the generators, so as to charge at light load and to discharge at heavy load. If the generators are shunt-wound and have a sufficiently drooping characteristic it would simply be necessary to connect the battery directly in parallel with the generators, care being, of course, taken that the battery is large enough for its work, and has a low internal resistance. Automatic charge and discharge will then take place according to the load on the generators. It is, however, not permissible to assume these conditions of generator, so that an arrangement, such as that shown in sketch, may be necessary to help the battery to charge and discharge at the proper times. B is a motor-driven compound-wound booster, with the field windings, S *s*, in opposition to each other. When

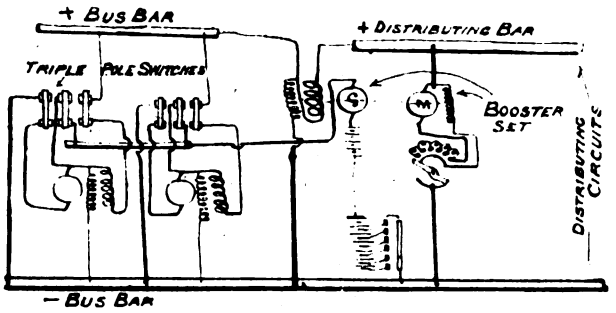


the current in the motor circuit is just equal to the output of the generators, the two windings neutralise one other, so that the booster does no work. Suppose that the motors, M, demand more than the output of generators, the series winding, S, will predominate, and cause the polarity of the booster to be such as to add pressure to the battery circuit, and so help it to discharge. When the current in the motor circuit falls below the output of the generators the shunt winding, *s*, will reverse the polarity of the booster, so that the pressure will be in the right direction for charging the cells. D is a change-over switch for cutting out the booster and paralleling the battery directly across the generator leads, if this should be desired.—P. S. T.

Answer to No. 281 (*awarded* 5*s.*).—Assuming that the generators mentioned in the question are compound wound, the accompanying diagram shows an arrangement which would accomplish the desired end. The generators are connected in the usual way with the equalising bar joined to the middle blade of a triple-pole switch. The apparatus necessary to enable the accumulators to automatically discharge on heavy loads and to be charged on light loads consists of a booster set, the motor part, M, of which is run directly off the mains, while the generator armature,

Digitized by Google

G, is placed in series with the battery. The battery and G are put across the negative and equalising bars. Between the positive generator 'bus bar and the positive distributing 'bus bar is placed the series winding of G, the shunt winding being connected as plainly shown. These two windings are so connected that they oppose one another, and their respective ampere-turns should be so proportioned that when the generators are working at about their normal load there is no field. Should the load now increase, the additional ampere-turns given to the series winding causes a few volts to be generated in the direction of discharge, thus causing the battery to take up all or nearly all the increase. When the load falls below normal, the shunt winding predominates, and voltage is generated in the opposite direction, thus assisting the generators to charge the battery. It will be understood that in the case of an overload, although the current in the series windings of the generators is increased (as arranged in the diagram), and consequently their pressures and output, the E.M.F. generated in the booster should be sufficient to ensure that the battery really does take most of the increase of load. The booster, G, and battery are placed across the equalising—not the positive—bar and the negative bar, for the same reason why compound-wound machines are not run in parallel without the use of an equalising bar, this arrangement being unstable. Should it be noticed during the daily working of the plant that the battery is not being sufficiently charged, the regulating switch can be operated to cut a cell or two out, so that at



normal load a small charging current will be passed; or, in other words, the point of equilibrium will be raised, thus increasing the duration of the periods of charge and decreasing those of discharge.—E. J. Evans.

Question No. 282.—What are the most important considerations to be observed when designing the ordinary condensing plant for a condensing engine in order that a good vacuum may be obtained in the low-pressure cylinder?

Best Answer to No. 282 (*awarded* 10*s.*).—The first consideration is whether the water available for condensing is suitable for after use in the boilers, for on this will depend the type of condenser used. If the condensing water is reasonably pure, a jet condenser may be used; if otherwise, a surface condenser must be employed. The former type is the more efficient, since the water and steam are thoroughly intermixed, and there are no power losses in driving pumps.

The three main points to be fixed in designing a jet condenser are: (*a*) weight of injection water required; (*b*) capacity (volume) of the condenser; (*c*) area of injector orifice.

(*a*) Taking the terminal pressure of the steam in the low-pressure cylinder at 10lb. absolute, each pound of steam contains about 1,140 B.T.U. above that contained by 1lb. of water at 32deg. F. The temperature of the mixture of condensed steam and water in the hot-well will be about 110deg. F. Take the temperature of the injection water at 50deg. F., then every pound of injection water gives up 110 − 50 = 60 B.T.U. But B.T.U. per pound of steam = 1,140 + 32 − 110 = 1,062 B.T.U. ∴ Weight of injection water per pound of steam $= \frac{1,062}{60} = 17{\cdot}7$lb. In practice, in order to ensure safety, about 25lb. to 30lb. water are allowed per pound of steam condensed.

(*b*) The volume of the condenser depends on the volume of the low-pressure cylinder, but different makers have different ratios. An average rule is to make the volume of the condenser half that of the low-pressure cylinder.

(*c*) The size of the jet can be found from the formula $A = \frac{W}{26\,v}$, where A = area of valve in square inches, W = pounds weight of injection water per minute, v = velocity of jet in feet per second (take this at 20ft. per second). In a surface condenser the chief points to be considered are (*a*) area of cooling surface, (*b*) amount of circulating water, (*c*) capacity of circulating pump.

(*d*) *Capacity of Air-Pump.*—(*a*) Let S = area of surface in square feet, W = weight of steam condensed per hour in pounds. Then the area of cooling surface can be got from the empirical formula, $S = \frac{17\,W}{180}$. (*b*) The temperature of the condensed water will probably not be the same as that of the condensing water. The difference may be taken at 35deg. to 40deg. F. Let H = number of heat units in 1lb. of steam above that contained by 1lb. of water at 32deg., T = temperature of condensed steam, t = temperature of circulating water on entering condenser, t_1 = temperature of circulating water on leaving condenser, W = weight of circulating water in pounds required for each pound of steam condensed; then $W = \frac{H + 32 - T}{t_1 - t}$. (*c*) The circulating pump may either be a piston or plunger pump, or a centrifugal pump. In the latter case a small special engine will be required. In the former case the pump can be worked from the main engine if desired. In the latter case the circulating pump must be of such size that the discharge capacity per minute is from $\frac{1}{40}$th to $\frac{1}{60}$th of the volume swept through by the low-pressure piston per minute. In the former case, if D = diameter of circulating pump in inches, L = length of stroke in inches, n = number of strokes per minute, w = total weight (pounds) of circulating water required per minute, then

$$D = 5{\cdot}86\sqrt{\frac{w}{n\,L}}.$$

(*d*) Either a vertical single-acting bucket pump or a horizontal double-acting piston pump is commonly used as an air-pump, the former type being preferable. Assuming that the pistons of the air-pump make the same number of strokes per minute as the piston of the engine, the capacity of the vertical single-acting pump will be: for jet condensing, $\frac{1}{5}$ to $\frac{1}{10}$ low-pressure cylinder capacity; for surface condensing, $\frac{1}{10}$ to $\frac{1}{15}$ low-pressure cylinder capacity. The capacity of the horizontal type will be: for jet condensing, $\frac{1}{8}$ to $\frac{1}{10}$ low-pressure cylinder capacity; for surface condensing, $\frac{1}{15}$ to $\frac{1}{25}$ low-pressure cylinder capacity. The difference between the capacities (*a*) jet condensing and (*b*) surface condensing is due to the fact that in the latter case the pump has to remove the condensed steam and any air that has entered with the steam, while in the former case the condensing water has to be dealt with in addition.

In the surface condenser, the cooling water may be passed either inside or outside the tubes (which should be of solid-drawn brass 16 to 19 B.W.G. thick and about $\frac{3}{4}$in. outside diameter). The former method is the more usual. The tube plates to be of rolled brass, the tubes pitched about $1\frac{1}{2}$in. apart, and secured by means of a gland or soft wood ferrule. The above data and formulæ are given on the authority of Messrs. Low and Bevis, in their "Manual of Machine Drawing and Design."—J. A. S.

Answer to No. 282 (*awarded* 5*s.*).—This question clearly refers to condensers of the ordinary jet or surface type, and it will therefore be advisable to state at the outset that the remarks below refer only to these types. There are so many points of detail, small in themselves, but any of which if badly designed will considerably impair the efficiency of the condenser, that it is somewhat difficult to point to those of most importance. In the writer's opinion the dimensions of the air-pump and the velocity of the bucket have probably the greatest influence upon the efficiency of the plant, and are the factors of first importance. The volume swept out by the bucket should not be less than one-tenth of the volume of the low-pressure cylinder for a jet condenser, and, of course, will be very much less for a surface condenser; also it is not desirable to have a higher bucket velocity than 250ft. per minute. Experience has amply demonstrated that a large diameter

Digitized by Google

and short stroke give a better result than a small diameter and a long stroke for a fixed air-pump volume. This is well illustrated by comparing the vertical type of pump, which undoubtedly produces a better vacuum than the horizontal type. The former, it will be noted, usually has a stroke of about one-third to one-half of the engine stroke, whilst the latter is more usually of the same stroke as the engine, since it is a common practice to work these air-pumps off the tail rod. Further, other conditions being similar, a single-acting pump is more efficient than a double-acting one. It may, therefore, be generally laid down that a short-stroke single-acting pump is the most efficient, and this should be borne in mind when designing, and, where practicable, adopted.

Another matter having an important bearing on the vacuum is the form of the condenser, which should be such that there are no spaces where air may be trapped or lodged, for if so this will greatly vitiate the vacuum. In the case of a surface condenser, the general form should be such that the circulating water will have to travel continuously through the tubes. In the jet condenser, a good mixture of the injection water and the steam to be condensed should be effected. In the surface type, the entering cold circulating water should meet the condensed steam leaving the condenser. The volume of the condenser may vary between fairly wide limits without seriously prejudicing the vacuum, but the usual proportion is from one-third to three-quarters the volume of the condensing cylinder. The injection or circulating pipes should be large enough to admit 30lb. of injection or circulating water per pound of steam used by the engine. The diameter of the injection pipes is governed by the velocity of the injection water, which in turn depends on the height and distance the water is drawn, so that if the supply is some distance from and below the condenser, large pipes are required. The practice of calculating the diameter of the injection pipes by making them some fractional diameter of the condensing cylinder is too empirical, and is to be discouraged. In all cases the head due to the height and vacuum should first be obtained, and then the loss due to friction of the pipes calculated, and this deducted from the above head to arrive at the effective head driving the water into the condenser. When there is a long length of injection pipes, a non-return or check valve is often fitted at the end of the pipes. This valve prevents the pipes entirely emptying themselves when the engine is stopped, and therefore when starting the engine the pump has not to draw so far, consequently the condenser gets its water more quickly and the maximum vacuum in the condenser is earlier obtained.

The area through the bucket, delivery, and foot valves is a detail that requires attention, and these areas should be sufficient. The exhaust pipes from the cylinder to the condenser should be large enough and as short as practicable to limit the drop between the condenser and the engine. In this connection it is desirable to note that a short exhaust pipe is attained in a tandem engine by putting the low-pressure cylinder at the back when an air-pump working off the tail rod is adopted, and at the front when the pump is worked from the cross-head, and therefore probably a vertical one.

Careful attention to the following details will also add much to the efficiency. The air-pump, parallel motion, slides, bearings, etc., should be of good proportions, so that they will not readily get out of alignment, otherwise there will be undue wear of the barrel or bucket with consequent loss of efficiency. The air-pump bucket is best made plain with water grooves, and not fitted with rings or springs, for this simple arrangement has been found by experience to give good results, and the liability to breakdown is very much reduced.—E. Y. T.

Answer to No. 282 (*awarded* 5*s.*).—As far as the condensing plant is concerned, a good vacuum in the low-pressure cylinder of the engine depends primarily upon three conditions: (1) length and condition of exhaust pipe connecting cylinder to condenser; (2) complete and speedy condensation of exhaust steam; (3) efficiency of the air pump.

(1) Under this heading little need be said except that, other things being equal, a condenser close to the cylinder and connected to it by a pipe, having as few joints as possible, will give better results than one placed some distance away.

(2) This is a matter of water supply, and in the case of a surface condenser a question of the number, arrangement, and tightness of the tube.

(3) With conditions (1) and (2) perfectly fulfilled, good results cannot be obtained without an efficient air-pump.

In order to make clear what to avoid in designing an air-pump, it may be instructive to compare two types of pump that have come under the writer's notice (see Fig. 1). This pump under most favourable conditions never maintained 23in. of vacuum. It will be seen that the water which has run in from the condenser traps the air back, much as sewer gas is kept in a drain. Air from the condenser has to find its way as best it can through the water and valves. In order to ensure quick closing on the part of the valves, the lift is small, consequently the inlets are much obstructed. The air, instead of passing freely through, tends to become intimately mixed with the water. The clearance above and below the bucket is considerable. If the pump were dealing with "solid" water this would be of no great moment, but with water containing a good deal of air the case is very different. Let us follow the bucket through a cycle of operations, beginning with the bucket in position shown. The "aerated" water over the foot valves has been compressed until the bucket valves have opened and

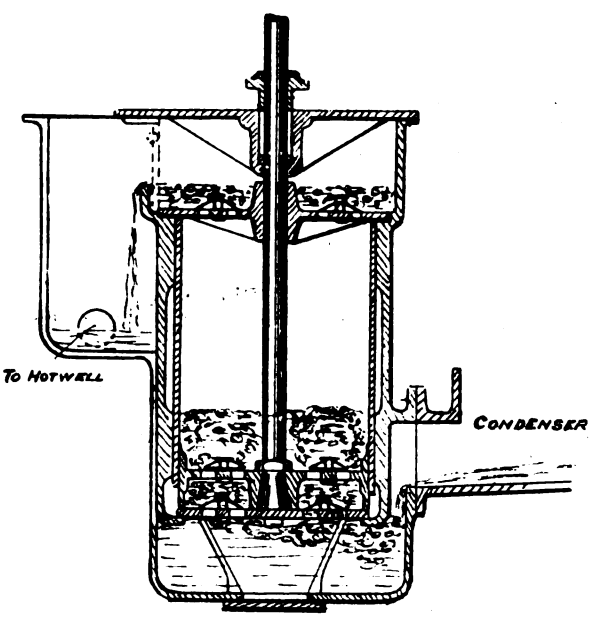


Fig. 1.

allowed all but the water in the clearance spaces to pass through. The bucket begins to move upward, and the air in the clearance spaces expands, filling up the space in the barrel below the bucket, which ought to be available for a fresh supply, and causing a certain amount of back pressure against the foot valves, which do not open until pressure in condenser is sufficient to overcome this back pressure. A similar state of affairs obtains between the bucket and the head valves. The air in the clearance water is compressed to something greater than atmospheric pressure to enable the pump to discharge into hot-well. This air re-expands during the down stroke, uselessly filling up the barrel, and causing a certain amount of back pressure against the bucket valves, which indirectly makes greater compression between bucket and foot valves necessary. More air is thus imprisoned to re-expand on the up-stroke, causing slightly greater back pressure against the foot valves. This increased back pressure delays the discharge from the condenser, as the supply of exhaust steam is constant, the pressure in the condenser naturally rises.

Fig. 2 shows another form of air-pump, from which some of the foregoing objections are absent. The condensed water and air have a free passage into the pump barrel through the ports shown midway along the cylinder. No bucket valves are needed, as the piston acts as a valve in blanking the ports when passing over them. The

Digitized by Google

clearance spaces between the piston and valve plates are as small as practicable. The amount of air a pump will throw depends upon the pressure at which air can flow into the barrel. It is, therefore, important that to maintain a good vacuum there should be no obstructions which can act as reducing valves between the low-pressure cylinder, the condenser, and the pump barrel. The object aimed at in an air-pump is to keep the pressure in the pump barrel as nearly as possible equal to that due simply to the temperature of the exhaust. This end is defeated by allowing large clearance spaces, as the compressed air so stored

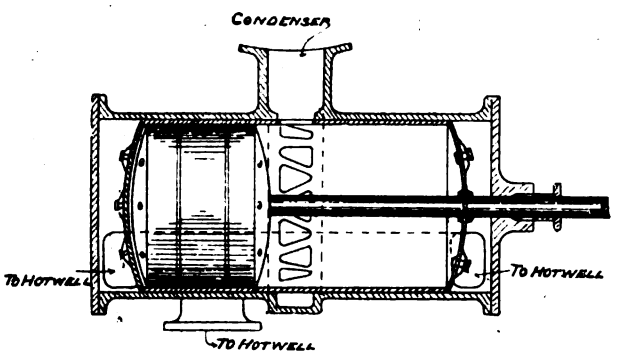

FIG. 2.

takes up space in the barrel, and, as already mentioned, creates a certain amount of back pressure which must be added to that against which the low-pressure cylinder has to exhaust. On similar grounds, it is also important that the pump should not have to discharge against any head of water caused by placing the hot-well on a higher level than the discharge valves.—P. S. T.

LEGAL INTELLIGENCE.

HYDE CORPORATION v. THE OLDHAM, ASHTON, AND HYDE ELECTRIC TRAMWAY COMPANY.

In the Court of Appeal, on Thursday last week, the hearing of the case of the Mayor and Corporation of Hyde *v.* the Oldham, Ashton, and Hyde Electric Tramway Company, Limited, and others, was concluded. It was an appeal against the decision of Mr. Justice Grantham, given some 12 months ago, granting the plaintiffs an injunction, restraining the defendants from laying wires called feeders under the footways in Hyde, for the purpose of working tramways which the defendants had constructed. Mr. Justice Grantham also awarded the plaintiffs £100 damages. Mr. Cripps, Q.C., instructed by Mr. Sydney Morse, London, represented the appellants, and Mr. McMorran, Q.C., and Mr. Sutton, instructed by Messrs. T. and A. Brownson, solicitors, Hyde, represented the respondents, the Hyde Corporation. After a somewhat lengthy hearing, the appeal was dismissed, with costs, subject to a variation of the injunction made by Mr. Justice Grantham.

COMPANIES' MEETINGS AND REPORTS.

ELECTRICAL POWER STORAGE.

Directors: John Irving Courtenay, Esq. (chairman and managing director); Sir Daniel Cooper, Bart., G.C.M.G.; Frederick Green, Esq.; Sir James Pender, Bart., M.P. Chief engineer: H. W. Butler. Secretary: David Smith.

The directors, in their report for the year ended May 31, 1900, state that the profit for the year is £5,309. 4s. 3d., and the balance brought forward from last year £554. 12s. 11d., together amounting to £5,863. 17s. 2d. Of this, £243. 1s. 1d. has been carried to reserve fund and £1,000 to contingent fund, and the directors recommend the payment of a dividend of 5 per cent. on the ordinary share capital, which will absorb a further £4,362. 8s. 5d., leaving £258. 7s. 8d. to be carried forward. The Company's buildings, plant, tools, etc., have been maintained in thorough repair and condition at a cost of £2,394. 10s. 2d., which sum has been provided out of revenue. The directors are glad to state that the demand for the E P.S. batteries increases year by year, and the recent extension of the works is being fully utilised. The orders on hand are larger in amount than at any previous time, and include several for tramway and power stations, the special type manufactured by the Company for this purpose having met with the entire approval of engineers. The development of the business has necessitated the introduction of further working capital, and a call of £1 per share has been made during the year on 3,132 ordinary shares on which only £3 per share had been previously paid. The directors regret to announce the death of Mr. Frank King, lately a director, and for many years manager of the Company. Mr. King had been in failing health for some considerable time, and his death in August last removed one of the pioneers of the storage battery industry. The retiring director is Mr. Frederick Green, who offers himself for re-election. The auditors, Messrs. James Meston and Co., chartered accountants, also offer themselves for re-election.

BALANCE SHEET.

EDMUNDSON'S ELECTRICITY.

The third ordinary general meeting of this Corporation was held on Friday last at the offices, Broad Sanctuary-chambers, Westminster, S.W., Mr. John R. Wigham, J.P., presiding.

The **Chairman** said the report was satisfactory. The profit for the year ended March 31 last amounted to £17,260, showing an increase of £6,000. During the period under review the capital had been increased by the issue of 9,400 ordinary shares, making the total capital £200,000, the full amount authorised. There had also been a further small issue of debentures, raising their total amount to £75,000. Among the assets was the large item of £121,000, under the heading of "sundry debtors and advances to subsidiary companies." The advances to subsidiary companies, which formed a large proportion of this item, represented money spent in connection with their various companies, in exchange for which they were entitled to get shares or debentures. Since the date of the balance-sheet this item had been considerably reduced by the transfer to the Company of many of these shares and debentures. The investments, standing at £111,000, had been taken at actual cost price, their par value being much larger. The Board recommended a dividend of 6 per cent. on the ordinary shares and the same rate on the deferred shares. They proposed to write £5,000 off the goodwill and to carry forward £4,152. The progress of the Company's stations during the past year had been greater in nearly every case than had been expected. The rapid increase in the use of the electric energy for all purposes had necessitated large extensions, and most of their work during the past 12 months had been devoted to such extensions. The Board had, however, secured powers for several other important towns which were then being confirmed in Parliament. Amongst these were Grantham, Stamford, Twickenham, Bishop Auckland, Weybridge, and Redruth. In addition, the directors had practically secured a concession for an electric tramway between Redruth and Camborne, which it was proposed to work in connection with the Company's Redruth central electric station. A considerable number of private installations for country houses, etc., had been carried out during the year, and others were in course of construction. As in last year, additional capital was required to meet the Company's extending business, and the directors proposed that the capital should be increased from £200,000 to £400,000, and they intended to at once issue £100,000 as 6 per cent. preference capital, reserving the remainder for issue when required. The Board thought it was in the interest of ordinary shareholders that preference shares should be issued instead of increasing the ordinary share capital. He then moved the adoption of the report and the payment of the dividends therein recommended.

Mr. W. R. Davies seconded the motion, and, after a short discussion, it was unanimously agreed to.

The **Chairman** next proposed: "That the directors be and they are hereby authorised to issue the remaining 20,000 new

Digitized by Google

shares, or such part thereof as they shall think fit, either as preference shares, ranking in all respects *pari passu* with the 6 per cent. preference shares above mentioned, or as ordinary shares of the Corporation."

Mr. Davies seconded the resolution, which was agreed to *nem. con.*

The resolutions for the increase of the capital were afterwards submitted to separate meetings of the ordinary and deferred shareholders, and adopted.

CITY OF LONDON ELECTRIC LIGHTING.

An extraordinary general meeting of this Company was held at Winchester House, E.C., on Wednesday last, when a resolution authorising the directors to borrow any sums not exceeding in the whole £400,000 in excess of the amount of the debenture stock of the Company outstanding, and the premium payable thereon on redemption, was confirmed.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Bermondsey.—The Vestry invite tenders for the erection of a generating station in Neckinger, Spa-road. Tenders by 26th inst.

Croydon.—The Council invite tenders for the erection of car sheds at the Thornton Heath and Brighton-road depôts. Tenders by July 18.

Sheffield.—The Corporation invite tenders for 12 months' supply of transformers. Tenders by 21st inst. Details in our advertisement columns.

Beckenham.—The Urban District Council invite tenders for Section G, free wiring contract. Tenders by July 16. Details in our advertisement columns.

Paris.—Tenders are invited for 11 lots of telegraph apparatus. Tenders, addressed to Post and Telegraph Department, 103, Rue Grenelle, Paris, by 24th inst.

Manchester.—The Tramways Committee invite tenders for the electrical equipment of 150 cars. Tenders by 21st inst. Details in our advertisement columns.

Cardiff.—The Corporation invite tenders for the manufacture and delivery of 10 30 kw. transformers. Tenders by 24th inst. Details in our advertisement columns.

Darlington.—The Corporation invite tenders for the supply and delivery of arc lamp posts and brackets. Tenders by 28th inst. Details in our advertisement columns.

Southend-on-Sea.—Tenders are invited for the supply and delivery of about 1,180 tons of steel girder rails and about 46 tons of steel fishplates. Tenders by July 25.

Birkenhead.—The Corporation invite tenders for constructing and erecting a new car shed in connection with the electric tramways in Laird-street, Birkenhead. Tenders by July 24.

Rugby.—The Urban District Council invite tenders for taking a lease of their powers under the Rugby Electric Light Order, 1898. Tenders by Aug. 1. Details in our advertisement columns.

Algemesi (Valencia, Spain).—The Municipal Authorities will receive tenders for the installation and working of the electric lighting by July 21. Specifications may be inspected at this office.

Salford.—The Corporation invite tenders for the supply, delivery, and erection of lighting cables, tramway feeders, and street lighting. Tenders by Aug. 13. Details in our advertisement columns.

Rome.—Tenders are invited by the Marine Department for electric lamps for the lighting of ships and arsenals. Particulars are to be obtained from and tenders addressed to the above Authority by 17th inst.

Kingston-upon-Hull.—The Corporation invite tenders for the electric lighting installation and fittings for the Springhead pumping station, near Hull. Tenders by 23rd inst. Details in our advertisement columns.

Sunderland.—The Corporation invite tenders for the supply and fixing of coal-conveying plant at the electric supply station, Dunning-street, Sunderland. Tenders by 27th inst. Details in our advertisement columns.

Algemesi (Spain).—Tenders are invited for an installation of public and private electric lighting. Specifications are to be obtained from and tenders addressed to the Municipal Authorities of the above place before July 21.

Wimbledon.—The Urban District Council invite tenders for supplying and fixing telephones intercommunicating between the various buildings forming the isolation hospital. Tenders by 18th inst. Details in our advertisement columns.

Hull.—The Electric Lighting Committee invite tenders for the supply and erection of five high-tension continuous-current rotary transformers, with switch gear and accessories. Tenders by 26th inst. Details in our advertisement columns.

Aston Manor.—The Urban District Council invite tenders for steam dynamo, motors, switchboard, pipework, storage battery, pumps, arc lamps and posts, travelling crane, and wiring. Tenders by 24th inst. Details in our advertisement columns.

Salford.—The Corporation invite tenders for the supply, delivery, and erection of the overhead equipment for the tramways in the borough, exclusive of the steel poles, but inclusive of their erection. Tenders by July 16. Details in our advertisement columns.

Southend-on-Sea.—The Corporation invite tenders for the supply and erection of boilers and auxiliaries, steam generators and switchboard and cranes, feeders and distributors, line equipments, trucks and car equipments. Tenders by July 25. Details in our advertisement columns.

Islington.—The Electric Lighting Committee invite tenders for relaying York and other stone and providing new York and other stone where necessary over the conduits and mains, as required, during the three years next. Tenders by 25th inst. Full details in our advertisement columns.

Hapton.—Tenders are invited for the lighting of Hapton township with electricity from Sept. 1, 1900, to April 30, 1901. Endorsed tenders to be sent to Mr. Ed. O'Shaughnessy, clerk to Hapton Parish Council, 16, Hammond-terrace, Padiham, by 31st inst. Full particulars on application.

Liverpool.—The Select Vestry invite tenders for an installation of about 100 lights in connection with the Parish Offices, Brownlow-hill. Specification may be seen at the office of Mr. H. J. Hagger, vestry clerk, Parish Offices, with whom tenders (sealed and endorsed) must be left not later than 19th inst.

Blackpool.—The Corporation invite tenders for the following works in connection with tramways extension: (Section A) trolley poles; (B) cables and trolley wires; (C) boosters and switchboards; (D) storage battery. Tenders will be received for any one or more sections, but not for part of a section. Tenders by July 23.

Madrid.—The Spanish Government invite tenders, not later than Aug. 18, for the concession of a system of electric tramway lines in Barcelona. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between 11 a.m. and 5 p.m.

Russia.—Tenders are invited by the Russian Government not later than the 28th prox. for the telephone service of Warsaw, St. Petersburg, Moscow, Odessa, and Riga. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 5 p.m.

Grays.—The Urban District Council invite tenders for the supply, delivery, and erection of the following work in connection with the electric lighting of the district: (Section A) two Lancashire boilers and pipework; (B) two 100 kw. steam dynamos, with boosters and balancer; (C) fuel economiser; (D) switchboard; (E) battery; (F) travelling crane; (G) mains and street lamp fittings. Tenders by Aug. 9.

RESULTS OF TENDERS.

St. Pancras.—The Guardians have accepted the tender of A. Sweet, at £13. 5s., for electrical firebells at St. Anne's Home.

Luton.—The Council have accepted the tender of Messrs. T. and E. Neville for the erection of electricity works, at £4,881.

Cheltenham.—The Town Council have accepted the tender of Messrs. Collins and Godfrey, at £1,873, for building extensions at the electric light works.

St. Pancras.—The Vestry have accepted the tender of the Western Electric Company, at £2,618, for laying additional mains in Tottenham Court-road and Euston-road.

Bermondsey.—The Vestry have accepted the tender of Messrs. W. T. Glover and Co. for the supply and laying of mains, conduits, junction boxes, etc., at £8,134. 7s. 9d.

Grimsby.—The following tenders have been accepted: Messrs. Chamberlain and Hookham, of Birmingham, for electrical meters, and Messrs. Mackenzie Bros., Edinburgh, for 60 arc lamps.

Newington.—The tender of the British Insulated Wire Company, at £9,026, has been accepted for the supply and laying of insulated electric mains, etc., in certain agreed side streets.

Stoke-upon-Trent.—The Guardians have accepted the tender of Messrs. R. Dawson and Co., Limited, Stalybridge, at £470, for the electric wiring of the new cottage homes at Penkhull, including overhead cables.

Longton.—The Town Council have accepted the following tenders: T. S. Bromage, chimney shaft and boiler-house for new electric light works; R. Goodwin, Longton, new workshops and stores for electric light works.

Leeds.—The Tramways Committe have accepted the following tenders for raising and extending the Hunslet car-sheds: I. Gould and Co., Limited, at £3,929. 14s., for all trades except ironwork; Clayton, Son, and Co., at £1,130. 16s. 6d. (subject to approval of Council), for ironwork.

London County Council.—The following tenders have been received for the lighting of the Farmfield Reformatory: Oil-engine—Bilbie, Hobson, and Co. (Hornsby-Akroyd engine), £257 (accepted); Priestman Bros., £312. 5s.; Crossley Bros., £324. Wiring, etc.—Tamplin and Macovskie, wood casing £309. 14s. 6d. (accepted), steel tubing £360; Strode and Co., £349 and £373; Concentric and General Contract Company, £360 and £440; F. A. Glover and Co., £407 and £450; Wood, £484 and £530; E. P. Rickson, £678 and 700. Dynamo—Parker and Co., 700 revolutions per minute £165 unfixed, 900 revolutions £143 unfixed; Electrical Construction Company, 620 revolutions, £139 fixed (accepted); Silvertown Company, 600 revolutions, £130 unfixed, £136 fixed; Siemens Bros., 720 revolutions, £182. Battery—Chloride Company, 25 amperes £159, 70 amperes short £183, 60 amperes long £327; Electrical Power Storage Company, £144, £158 (accepted), and £278. Cables—British Insulated Wire Company, £174 per mile (accepted).

Digitized by Google

BUSINESS NOTES.

TRACTION.

Camborne and Redruth Tramway Bill.—The preamble of this Bill has been proved.

Eccles.—The Council have decided to advertise for a consulting electrical engineer, to advise generally on the electrical equipment of the tramways.

Nelson.—The Council have decided to give notice to the Burnley and District Tramways Company for the purchase of so much of the tramways as are in the borough.

Swansea.—It is reported that the first week's running of the electric tramcars has been a great success. No less than 95,000 passengers have been carried, and this without a single mishap.

Hull.—During the past 12 months the electric trams have carried 9,902,104 passengers, the total receipts for the year being £42,258. 15s. 4d. The net profit on the trams for nine months ending March 31 last was £9,990. 14s. 4d.

Wolverhampton.—The Tramway Committee are asking for permission to purchase several plots of land on the Newhampton-road in order to widen it for tramway purposes, and to employ an assistant borough surveyor to devote his time to tramway work.

Kirkcaldy.—Considerable purchases of property will be necessary in connection with the Kirkcaldy tramway scheme. The tramway will commence from the west end of Linktown and terminate at Gallatown. Prof. Kennedy has the building of the cars already under consideration.

Newport.—The Council have authorised the Tramways Committee to accept tenders for rails and fishplates, and agreed to a strengthening of the committee by the addition of Alderman Moses, Mr. G. H. Llewellyn, and another member of the Electricity Committee to assist in the decision as to the system of electric traction for the Corporation-road route.

Dewsbury.—The General Purposes Committee's last report states that they had supported the British Electric Traction Company in their endeavour to preserve the free use of the intended tramway from Cleckheaton through Dewsbury to Ravensthorpe; also that they were seeking an interview with Messrs. E. Fox and Sons respecting their proposal for the opening out of Watergate, on the bank of the Calder, as a wide public road.

Rawmarsh.—A requisition on behalf of the Sheffield and South Yorkshire Navigation Company for leave to withdraw their opposition to the Urban District Council's Tramways Bill has been deposited in the Private Bill Office of the House of Commons. The Bill is now unopposed, and has been referred to the consideration of the committee on unopposed measures in the Commons. It has already been passed by the House of Lords.

Newcastle.—At the last meeting of the Town Council a letter was read from the secretary to the Potteries Electric Traction Company, Limited, who wrote in reply to a communication from the Council asking that the tramway system might be continued from Newcastle to Trent Vale, on the Trentham-road, that the matter had been receiving the consideration of his Board for some time and was down again for discussion at the next Board meeting.

Stockton Heath.—The Council have passed the following resolution: "That it is desirable that a representation be made to the Warrington Corporation with the view of getting their tramway system, subject to satisfactory terms and conditions, extended to Stockton Heath, and that a committee of the Council, together with any representative ratepayer or ratepayers, be appointed to wait upon the town clerk of Warrington and confer with him on the subject."

Wakefield.—At the recent enquiry held by the Light Railway Commissioners it was pointed out that a serious obstacle to the carrying out of the proposed tramways scheme for Wakefield was the narrowness of the old bridge (belonging to the county) which spans the Calder at the bottom of Kirkgate. The Commissioners suggested that a new footbridge should be erected alongside it for the use of the public, and that the County Council, the Corporation, and the promoters of the scheme should divide the cost.

Liverpool.—The recommendation of the Tramways Committee, "That a society, to be called the Liverpool Corporation Tramways Benefit Society, be established in accordance with rules now submitted, and that an addition be made to the wages of every employé in the tramways service who joins the society equivalent to 33⅓ per cent. of the amount of such employé's subscription to the society, and that such addition be paid to the treasurer of the society during the pleasure of the Council," will again come before the City Council next week.

Salford.—The General Purposes Committee on Wednesday confirmed the recommendation of the Tramways Sub-Committee to discontinue negotiations with the Manchester Carriage and Tramways Company for the working of the trams in Salford, Swinton, Pendlebury, and Eccles after April 27 next, and also that the Corporation work the tramways after that date by horse traction until such time as the arrangements are completed for the electrical working was considered. They further agreed to advertise for tenders for the equipment to carry on the present system.

Ayr.—An arrangement has been approved of whereby the electric power for the tramways is to be given from the present generating station in Mill-street at the cost of production—that is, at the rate of about 1d. per unit, the price at which it is expected the current may be produced a year hence. Mr. A. J. Fuller, the electrical engineer, has submitted the following comparative statement, showing a steady reduction in the cost of producing the current: 1897—output, 120,000 units, cost 3·61d.; 1898—161,000 units, cost 2·8d.; 1899—297,000 units, cost 2·03d.; 1900—433,000 units, cost 1·7d.

Moss Side.—The District Council have asked the Manchester Carriage and Tramway Company to discontinue the jumping of the cars at the junction of Raby-street and Princess-road, and remonstrated on the collection of cars and the behaviour of carmen at the end of Princess-road. It has been ordered that Askham's spring points be fixed at the corner of Moss-lane East and Raby-street, and that a new cast-iron point be fixed on the tramway in Moss-lane West, and that any repairs deemed urgently necessary to the lines in Moss-lane West, Alexander-road, and Yarburgh-street be forthwith executed.

Derby.—The receipts of the Corporation tramways during the four weeks ended June 23, 1800, amounted to £1,409. 3s. 10d., being an increase of £151. 16s. 2d. as compared with the corresponding period last year. The Tramways Committee have had under their consideration the joint reports of the borough surveyor and electrical engineer relative to the proposed tramway extensions. The committee are of opinion that the tramway system should be extended, and that electric traction should be adopted. The Council have authorised the committee to prepare a scheme of electric tramways, and submit the same to the Council for approval.

Bradford.—The minutes of the Tramways Committee show that the engineer having reported on the estimated cost of extending the electricity cables from the top of Whetley-hill along Toller-lane and Duckworth-lane to Ladye Royde Hall and Daisy Bank and neighbourhood, and as to the probable annual revenue to be derived from customers on such extension, the committee had resolved that the engineer be authorised to lay down such extension, and also to extend the electricity cables from Duckworth-lane along Pearson-lane to its junction with Allerton-lane, thence along Allerton-lane to Four Lane Ends, and thence along Thornton-road to the junction of such road with Whetley-lane, to couple up with the existing cable at that point.

Reading.—The Town Council have passed the following resolutions: (1) "That as soon as possible after the Reading Corporation (Tramways) Act, 1900, shall have received the Royal assent the town clerk do obtain prints thereof and forward a copy to each member of the Council; and that the Tramways Committee do thereupon consider and report to the Council as to the steps to be taken for carrying into execution the powers which will be conferred upon the Corporation by the Act." (2) "That if the Court of First Instance should give a decision adverse to the Corporation in the pending action by the Reading Tramways Company, Limited, all requisite steps be taken on behalf of the Corporation for entering and prosecuting an appeal against such decision."

Darlington.—At a meeting of the Darlington Town Council on Tuesday it was resolved that the Light Railway Commissioners be informed that if the company are not prepared to carry out the whole scheme of light railways in its entirety, as proposed by the company and supported by the Corporation at the public enquiry before the Light Railway Commissioners held in August last, with the modifications thereto which have been subsequently agreed to by the Corporation, and which are referred to in the report, the Council will consider the expediency of making an application for a new order at an early date. It was also agreed that the tramway company should forfeit a sum of £5 to the Corporation for every day after the expiration of the period for completing the tramways until such lines be completed, if the company carry out the work.

Dundee.—On Tuesday considerable commotion was occasioned, says the *Glasgow Herald*, by the report that it had been found impossible to bring north the new electric cars which have been manufactured in England for Dundee. The cars were railed several days ago, but after completing part of the journey the train which they were being conveyed in was stopped, it having been learned in the interval that the cars, while able to pass under the English railway bridges on account of their span being sufficiently high, would be likely to collide with the bridges on the North British Railway system, over which it had been arranged they should pass. It is stated that the bodies of the cars may have to be taken off the bogies and rebuilt on their arrival at Dundee. Meanwhile it is understood they are standing at one of the junctions on the Midland Railway.

Birmingham.—The report of the Judicial Sub-Committee, adopted on Tuesday, stated that the three months' trial which was agreed to be given to the new loop line in the Old-square expired on Monday, July 2. In his report the chief constable stated that special attention had been given to the Old-square during this period, and it had been found that two cars could be loaded at the same time without causing obstruction, thus preventing a great deal of congestion of tramcars and passengers which constantly occurred under the old condition. The cars kept much better time, and altogether the new arrangement had proved highly satisfactory. The sub-committee recommended that the Public Works Committee be now asked to take up the old metals and repave the Old-square in accordance with the arrangements made with the Aston Tramway Company.

Isle of Man Tramways.—The petition of a creditor of the Isle of Man tramways to have a liquidator appointed and the company wound up compulsorily was to have come by adjournment before Sir James Gell on Tuesday. The directors had, since the appointment of an interim receiver a month ago, approached many of the largest creditors, with, they thought, satisfactory results. About £150,000 was required to meet the most pressing claims, and they had reason to hope that if the shareholders could be induced to

Digitized by Google

subscribe £50,000 more the balance could have been found, and the company saved from compulsory liquidation. The *Financial Times* states that on the 11th inst. the petition for the compulsory winding up of the Isle of Man Tramways and Electric Power Company, Limited, came on for hearing in the Manx Chancery Court. The order was not further objected to by the new directors, who had been unable to make arrangements to place the company on a satisfactory financial position. Mr. W. H. Walker was appointed liquidator. The directors suggested that Mr. Edward Martin should be appointed with him, but it was pointed out that Mr. Walker would later on be acting as receiver for the debenture holders on a separate undertaking, and Mr. Martin's name was withdrawn.

Glasgow.—The tramway accounts were approved by the Corporation last week. The Chairman, in presenting the same, said the revenue for the year was £469,000, being an increase over the previous year of £30,000. The working expenses of horse traction had been 8 81d., as against 6·26d. for electric traction. In other words electric traction had cost 2½d. per car mile less. Then the receipts from the electric traction cars had been 14d. per car mile, while from horse traction they had only been 11·30d. per car mile, or 2½d. in favour of electric traction. If the cost of the working of the whole system by electric traction was in the same ratio as the small part they were working now, and he was convinced that it would be less, it meant a saving on the present mileage of £115,000 per annum, less the additional sinking fund on capital. On the other hand, if they could assume, as he thought they fairly might assume, that the passengers would also increase to such an extent as would give them an increase of 2½d. per mile, that meant an increase of £230,000 per annum, less the amount spent on working expenses. The more they had considered the question the more thoroughly were they convinced that when electric traction was in operation all over the city it would be an undoubted success. They had borrowed during the year £345,000, and they had a good deal more to borrow.

Folkestone.—The Tramway Special Committee of the Corporation have resolved that the routes previously approved be adhered to, with the exception that there be substituted for proposed route No. 6 (Bouverie-road East, Bouverie-road West to Grimstone-avenue, Grimstone avenue to Shorncliffe-road) a line from the town hall westward along Sandgate-road to the boundary of the urban district at the top of Sandgate-hill. The town clerk has been authorised to inform the clerk of the Cheriton Urban District Council of the steps now being taken by the sub-committee, and to approach the Urban District Council of Sandgate and the South-Eastern Railway Company upon the subject of connecting up the proposed Folkestone system of tramways at the top of Sandgate-hill with the existing tramway of the South-Eastern Railway Company in Sandgate. It was also resolved that the sub-committee is of opinion that the system for supplying current for working the tramways should be other than the overhead system, and that the routes adopted be amended by including that portion of Dover-road between a point opposite Bellevue-street and Rendezvous street, and also so much of Foord-road as lies between the junction therewith of Grace-hill and Tontine-street, and that the proposal to lay tramways along Kent-road and Bradstone-road be not carried out. The services of a consulting engineer are to be obtained to assist this sub-committee, in conjunction with the borough engineer, by advising as to the probable cost of the proposed scheme of tramways. The General Purposes Committee recently resolved that the Tramways Special Sub-Committee be requested to take into consideration the question of negotiating with Lord Radnor for the laying of tramways along the Lower Sandgate-road to the boundary between the urban districts of Folkestone and Sandgate, and forming there a junction with the tramway of the South-Eastern Railway Company.

Govan.—The following arrangement has been arrived at with regard to the conversion of the tramways: (1) the lines belonging to the burgh of Govan to be converted for overhead electric traction so as to be worked as one system with the Glasgow tramways; (2) the lease of the Govan lines to the Corporation to be extended for 21 years after the termination of the existing lease—viz., to 1935; (3) the conditions of the existing lease to remain in force, except as modified by the new agreement; (4) the Corporation of Glasgow to carry out the work of converting the lines (including the renewal of the permanent way, the laying of ducts and cables, the erection of overhead work, etc.), finding the capital therefor, which they would reduce by a sinking fund of their own, and to undertake to maintain the whole lines, cables, and overhead construction, and leave them in good working order at the termination of the extended lease, but the lines and all overhead electrical construction in the streets to be and remain the property of the Govan Commissioners during the whole period of the extended lease; (5) the Corporation to continue to pay interest and sinking fund upon the capital sum expended by the Commissioners under the existing lease till the termination of the extended lease; (6) the Corporation to pay all owners' assessments on the Govan lines as from the date when these are worked by electricity; (7) the Corporation to have power to sublet or to alter the existing tramway depôt in Govan, and not to be under obligation to restore the existing buildings at the end of the lease, provided they leave buildings equal in value to those now on the ground, but the other obligations as to payment of feu-duty, etc., not to be affected; (8) the Corporation to agree that the arrangement made in December last with the engineers and boilermakers as to the height of trolley wires should be applicable to Govan, or, at the option of the Commissioners, that the side-pole construction should be adopted in Govan-road between Linthouse and Cessnock, so as to leave one side of the road open; (9) all fares, tolls, and charges levied by the Corporation within Govan to be at the same rate as those charged generally within the city; (10) the Corporation to give a satisfactory through service of cars from Govan to the city.

LIGHTING AND GENERAL.

Lancaster.—The profit of the electricity department for the year is £420. 18s.

Neath.—It is proposed that the Council apply for an electric lighting provisional order.

Batley.—The Town Council have obtained sanction to a loan of £22 231 for electrical works.

Darlington.—The Town Council have decided to advertise for an electric lighting engineer.

Accrington.—A circular, with form of application, for the supply of electricity, has been issued.

Buxton.—Mr. Leeming, of Blackburn, has been appointed assistant engineer to Mr. Calvert.

Long Eaton.—Mr. Crowther, of Wallasey, has been appointed consulting electrical engineer to the Council.

Broughty Ferry.—The scheme for the electric lighting of Broughty Ferry will not at present be proceeded with.

Inverness.—In consequence of a petition from ratepayers the Council have agreed to abandon the electric lighting scheme.

New Malden.—The Surrey County Electric Lighting Company intend to apply for an order to supply the district with electricity.

Warwick.—The British Electric Traction Company intend to apply for a provisional order for lighting the town with electricity.

Leamington.—The Corporation's offer to buy the Midland Electric Light Company's undertaking for £17,000 has been refused.

Gloucester.—The Electric Light Works Committee will receive applications for a borough electrical engineer at a salary of £250 per annum.

London Gazette.—The estate of J. E. Stott, Huddersfield (trading as James E. Stott and Co.), has been released from trusteeship.

Richmond (Yorks).—The North British Electric Light Company intend to apply for a provisional order to supply Richmond with electric light.

Chesterfield.—In view of the large demand for private lighting it has been decided to postpone the question of street-lighting with arc lamps.

Aston Manor.—The Urban District Council have accepted Mr. G. H. Jack's estimate of £1,791 for the electric lighting of the Witton Hospital.

Harwood.—A syndicate intends to apply for an order to supply electricity within the urban districts of Rishton, Great Harwood, and Clayton-le-Moors.

Limerick.—Mr. Cowen held an enquiry on Wednesday into the application of the Corporation for sanction to a loan of £20,000 for electric lighting purposes.

Blairgowrie.—A committee is considering the intended application of the North British Electrical Supply Company to supply electricity within the district.

Woodford.—The County Electricity Supply Company intend to apply for a provisional order to supply electricity in Woodford, Wanstead, and Buckhurst Hill.

Nantwich.—The Council's Electric Lighting Bill for a provisional order having received the Royal assent, the surveyor is preparing a map showing the lighting area.

Smoke Nuisance.—On Monday at Blackpool the town clerk was fined 10s., or 14 days, for allowing thick smoke to issue from the Corporation electricity works.

Pudsey.—The District Council have decided to oppose the Northern Counties' Electric Supply Company's proposal to supply electricity in the Pudsey district.

Bradford.—Further progress has been made with the proposed acquirement of a loan of money for the instalment of the electric light in the Bradford Workhouse.

Peterhead.—The National Telephone Company have agreed to the stipulations laid down by the Council in regard to the erection of a line of poles on the South-road.

Salford.—The resolution with regard to the constitution of the Electric Lighting Committee, mentioned in our last issue, was defeated last week by 29 votes to 12.

Wolverhampton.—The Lighting Committee are about to ask the Council to agree to a reduction of their charges for the supply of electricity for lighting and energy.

Crewe.—The question of borrowing £10,000 for electric lighting extensions has been referred back, with a recommendation that the extension scheme be not proceeded with.

St. Andrews.—A special committee has been appointed to consider the intended application of the North British Electricity Supply Company to supply electricity within the burgh.

Warrington.—The building strike is delaying building operations at the electric lighting station. It is therefore not likely that the works will be completed as early as anticipated.

Tonbridge.—The Electric Lighting Committee have recommended that Mr. Hammond's report on electrical supply should be printed, but the matter has been deferred for a month.

Consett.—The Northern Counties' Electricity Supply Company intend to apply for an order for the district. Some members of the Council are in favour of obtaining an order themselves.

Digitized by Google

Whitechapel.—The District Board have decided to spend a further £44,670 in the supply of electricity in the district.

Matlock Bath.—The Urban District Council have decided to oppose the North British Electric Company's application for a provisional order to supply power in Matlock Bath district.

Partnership.—Mr. John M. Henderson has assumed his son, Mr. John M. Henderson, jun., as a partner. The business will be carried on in future under the style of John M. Henderson and Co.

Croydon.—The salaries of the officials in the electricity department have been raised all round, that of the borough electrical engineer to £450, with annual increments, till £600 per annum is reached.

Eastern Extension, Australasia, and China Telegraph Co.—The directors have declared an interim dividend for the quarter ended March 31 of 2s. 6d. per share, tax free, payable on the 14th inst.

Crieff.—The North British Electricity Supply Company intend to apply for a provisional order for power to supply electrical energy for public purposes within the area of the Crieff local authority.

Helensburgh.—The Burgh Commission intend to oppose the proposed application of the North British Electricity Supply Company for power to supply energy within the jurisdiction of the local authority.

Derby.—The sum of £850 has been granted by the Town Council for laying electric lighting mains to the infectious diseases hospital, and application is to be made for sanction to the borrowing of that amount.

Bromley.—The Council have confirmed a notice by the Foots Cray Parish Council under the Act of 1882 as to the scheme for the electric lighting of Foots Cray, lower borough of Chislehurst, Sidcup, and part of Bexley.

Globe Telegraph and Trust Co.—The directors announce a dividend of 4s. 6d. per share on the ordinary shares, making, with the previous distributions, a total dividend for the year of 5¼ per cent., carrying forward about £950.

Kelso.—At a meeting of the Burgh Commissioners on Tuesday it was stated that if the price of lighting the gas lamps were raised a resolution would be brought forward that the Commissioners adopt a scheme of electric lighting.

Berkhamsted.—The North British Electricity Supply Company intend to apply in December for powers in the district under the jurisdiction of the Council. The question will come before the Urban District Council next month.

London County Council.—At the usual weekly meeting of the Council on Tuesday it was agreed to lend the Fulham Vestry £50,519, the Islington Vestry £8 579, and the Shoreditch Vestry £21,905 for electric lighting purposes.

Newington.—The salary of Mr. Blaikie, resident engineer, has been increased by £50 per annum, on the understanding that Mr. Blaikie remains in the service of the Vestry and their successors for a period of two years at this salary.

Camborne.—The North British Electric Light Supply Company, whose headquarters are at North Shields, intend to apply for a provisional order authorising them to supply electric light for public and private purposes for the urban district of Camborne.

Pontefract.—The North British Electricity Supply Company intend to apply for a provisional order to supply electrical energy to the borough. The clerk has been instructed to report as to the steps to be taken by the Council to give such supply themselves.

Largs.—The North British Electric Supply Company, South Shields, intend to apply for a provisional order authorising them to supply electrical energy to the burgh. The Commissioners have resolved to ask for further particulars before taking any action.

Sowerby Bridge.—The North British Electricity Supply Association intend to apply for a provisional order for supplying electrity within the area of the District Council, who have during the present session of Parliament received a provisional order for the some purpore.

Chiswick.—The Chiswick electrical lighting company are prepared to wire the new town hall free of charge, the installation to remain the property of the company for 10 years; the charge for current to be at the rate of 6d. per unit. The wiring of the building will cost £500.

Direct United States Cable Co.—The directors announce a final dividend of 3s. per share and a bonus of 2s. per share, payable 31st inst., making, with interim dividends, 3½ per cent. for the year ended 30th ult., and £10,000 is placed to reserve fund account and about £3,700 carried forward.

Gomersal.—The North British Electricity Supply Company and the Northern Counties Electricity Supply Company intend to apply for provisional orders authorising them to supply electrical energy in the Council's district. The matter will shortly be brought before the Council for consideration.

Spalding.—The United Electric Light and Traction Company, Limited, have served a notice on the Urban District Council of their intention to apply to the Board of Trade for a provisional order authorising them to supply electricity for public and private purposes within the area of the Council.

Cupar-Fife.—The Lunacy Board have adopted the report of Bailie Mackenzie, Edinburgh, which states that the estimated cost of the introduction of the electric lighting system at the asylum at Springfield was £3,050. Estimates for the introduction of electric lighting into the asylum are to be obtained.

Browett, Lindley, and Co.—We learn that Messrs. Browett, Lindley, and Co., of Patricroft, Manchester, have recently opened a London office at 6, Old Queen-street, Westminster, S.W., under the supervision of Mr. Thos Browett. The general correspondence will still be carried on from the works in Manchester.

Lytham and St. Annes.—The Council have decided that inasmuch as the St. Annes Land Company refused to allow the Council to retain the portion of land intended for the site of the electricity station, the whole plot be given up. Electric lighting mains are to be laid along Victoria-road and Fairhaven-road.

Crompton and Co., Limited.—The directors will recommend at the approaching general meeting a dividend at the rate of 9 per cent. per annum for the half-year, free of income tax, making with the interim dividend paid in January last 7½ per cent. for the year. A sum of £12,000 will be added to the reserve fund.

Appointments Vacant.—The Corporation of Darlington invite applications for the appointment of borough electrical engineer.—The Ilford Urban District Council are prepared to receive applications for the appointment of a clerk of works for their electric light station and cable-laying. Full particulars will be found in our advertisement columns.

Northampton Institute.—The engineering day courses in mechanical, electrical, and horological engineering will be started on Monday, Oct. 1, 1900. Entrance examination on Wednesday and Thursday, Sept. 26 and 27. Particulars of the courses can be obtained on application at the office of the institute, or to the principal, Dr. R. Mullineux Walmsley.

Perth.—In connection with the application of the National Telephone Company, Limited, for permission to erect poles and wires along the road from Bridge of Earn to Freeland and Invermay, the Standing Sub Committee has granted the permission on the conditions embodied in the existing agreement between the District Committee and the company. The company has also been granted permission to erect telephone poles and wires along the highways leading from Cherrybank to Dupplin on the same conditions.

Stranraer.—The Town Council on Monday evening had under consideration a notice from the North British Electricity Supply Company, South Shields, of intention to apply for a provisional order whereby it was proposed to supply electrical energy for public or private purposes within the burgh. Satisfaction was expressed at the intimation, and more especially in view of the recent announcement of the Stranraer Gas Company raising the price of gas from 4s. 7d. to 5s. per 1,000ft. The communication was remitted to the Lighting Committee.

Fire.—With regard to the fire which occurred at the British Insulated Wire Company's works at Prescot late on Tuesday, we are informed that the occurrence was of a comparatively trivial nature. A drum of cable in the drying oven caught fire and was quickly extinguished by the firm's own fire brigade. The damage done to the buildings was almost negligible, but a good many drums of cable in course of manufacture were spoiled by smoke and water. The whole factory was working as usual on Wednesday, and no inconvenience will be caused to customers, except those for whom the damaged cables were being built, and in this case it will only mean a few days' delay.

Bath.—The Electric Lighting Committee have resolved that local wiring contractors be requested to have their business premises or private houses wired and connected to the mains. Any wiring contractor so connected who engaged a canvasser to be employed for canvassing for electric lighting to be allowed a commission of 1s. for every 16-c p. lamp wired, according to the Corporation regulations, by such contractor, and connected by the authority in private houses during each quarter. A committee has been asked to consider the possibility of the Corporation putting in fittings on the understanding that they should be paid for at so much per quarter, or a certain sum added per unit consumed.

Stock Exchange.—The Stock Exchange Committee have ordered to be quoted in the official list Edison and Swan United Electric Light Company, Limited, provisional certificates for £100,000 5 per cent. second debenture stock. Applications have been made to the committee to appoint a special settling day in, and to grant a quotation to, the Axminster and Lyme Regis Light Railway Company, shares of £10 each; Babcock and Wilcox, Limited, ordinary shares of £1 each and preference shares of £1 each; and the Metropolitan Electric Supply Company, Limited, further issue of £125,000 3½ per cent. mortgage debenture stock. The committee have further been asked to allow the British Aluminium Company, Limited, 20,000 7 per cent. cumulative preference shares of £10 each, fully paid, Nos. 1 to 20,000 (renewed application), to be quoted in the official list.

Birmingham.—At a meeting of the Electric Supply Committee on Wednesday a report was received from the engineer with reference to the recent interruption in the electric service in the centre of the city. The delay was caused, it was stated, by a defect which was inseparable from the system upon which some of the older mains were laid, and it is with a view to preventing a recurrence of the inconvenience that these mains are being relaid upon an improved principle. It was also announced that the Lord Mayor, acting with the informal concurrence of the committee, had purchased the site of the old General Hospital for the purposes of the department. The action of the Lord Mayor was approved. In making the purchase the committee had in view the growth of the electric supply undertaking, and the possible needs of a central station in connection with the local tram systems.

Digitized by Google

Llanelly.—The contract for the electric installation at the Old Castle Works has been let to Messrs. J. C. Howell, Limited, electrical engineers, Llanelly. The plant to be laid down will be of the most modern type, and will be complete in about a month's time. The installation will include 12 arcs and about 300 incandescent lamps.

New Issue.—The United River Plate Telephone Company are making an issue of 23 361 5 per cent. cumulative preference shares of £5 each, at par. The prospectus states that the growth of the company's business calls for extended alterations in its plant at Buenos Ayres, for which purpose the present increase of capital is chiefly required.

Lewes.—At a recent special meeting of the Town Council it was reported that the whole matter of the transfer of the electric lighting order had been dealt with; the costs—£550—paid over by the company, and the deeds and agreements duly completed. Great satisfaction was expressed at the conclusion of this long and troublesome transaction.

Stroud.—The United Electric Light and Traction Company, Limited, intend to apply to the Board of Trade on or before Dec. 21 next for a provisional order authorising the supply of electricity for public and private purposes in this district. The Lighting Committee are discussing the action the Urban District Council should take in the matter.

Bournemouth.—The Guardians are in favour of establishing electric lighting in the workhouse upon the lines of a report received from Mr. George R. Peers of Manchester. The estimate is £1,610, and they have decided to refer the matter to the House Committee. In the meantime Mr. Peers has been asked upon what terms he would prepare plans and specifications.

Bermondsey.—The Vestry have resolved to apply to the London County Council for a loan of £4,500 for the purchase of the Hanover Arms beerhouse, which stands on a part of the site in the Neckinger required for the generating station, and to apply to the County Council for a loan of £21,000 to defray the cost of erecting a dust destructor and a chimney shaft, and also of laying mains.

Thornhill.—The Northern Counties Electricity Supply Company, Newcastle-on-Tyne, intend to apply to the Board of Trade for a provisional order to supply electricity in the Council's area. The Council have asked the company to submit, in writing, a draft of the proposed measure which they sought to have passed, and then meet the Council at Thornhill at their next monthly meeting.

Wakefield.—Mr. H. Percy Boulnois has held an enquiry into the application of the City Council for sanction to borrow £25,000 for electric lighting purposes. Mr. Blackmore (city electrical engineer) explained that it was intended to duplicate the mains in various parts of the city, and to lay down additional plant capable of supplying 25,000 8-c.p. lamps, and 50 arc lamps for street-lighting.

Eastern Telegraph Co.—The directors announce that the accounts show, after payment of the interim dividend of £1. 5s. per cent. on the ordinary stock to Dec. 31, a balance available sufficient to pay a final dividend of £1. 5s. per cent. and a bonus of £2 per cent., both tax free, on the ordinary stock, payable on the 19th inst., making a total distribution of 7 per cent. for the year ended March 31.

Bradford.—It is suggested that the Corporation should extend the electric lighting cables (at an estimated cost of £2,300) to Daisy Hill for the supply of electricity to Mr. Illingworth's residence, and to other property in the district. At the special meeting to be held on July 17 a resolution will be proposed to empower the Electricity Committee to borrow £140,000 for electric station plant and mains extensions.

Banbury.—The Banbury and District Electric Supply Company, Limited—a company which has been formed by the Electrical Distribution Company, Limited, for the working of the order applied for for the borough—intend to apply for a provisional order in the coming session. This is only a precaution in case of any interference with the passing of the Confirmation Bill now before Parliament.

Stockton.—Mr. Ford (gas manager) has been requested to submit to the Town Council an estimate of the cost of extending several electric light mains, and to ascertain the probable number of new customers. The Rural District Council is to be approached with a view of obtaining their permission to lay the electric light main in the districts of Norton and Hartburn should the inhabitants of those townships make application for a supply of electricity.

Falkirk.—Notices have been received both from Edmundson's Electricity Corporation, Limited, and the United Electric Light and Traction Company, Limited, of intention to apply for a provisional order authorising the supply of electricity for public and private purposes within the Council's area. The Council have decided to oppose any application for a provisional order, and to remit the matter to the Lighting Committee for further consideration.

City of London.—A Select Committee of the House of Lords, presided over by Earl Rosse, have proved the preamble of the Bill promoted by the Charing Cross and Strand Electricity Supply Corporation to establish a generating station at West Ham to enable them to supply electricity to the City of London. The Bill has already passed the House of Commons. The Lords' amendment to the City of London Electric Lighting Company's Bill have been agreed to.

Rochdale.—The Electric Lighting Sub-Committee have agreed to lay the requisite cable to supply electric light to the new Board school at Heybrook, provided the School Board would agree to take the supply for at least three years. The committee hope to start the new electricity works in the course of perhaps a couple of months, and when the works have been handed over to the Corporation in working order a separate electricity committee will probably be formed.

Castle Donington.—It is proposed by one of the largest electrical engineering firms in the country to utilise the water power at King's Mills, Castle Donington, in the construction of an electrical plant, by means of which it is intended to supply Castle Donington and the neighbouring towns with the electric light. It is estimated that a force of 500 h.p. is being wasted at the mills, and that once the necessary plant is installed the cost of maintaining the works will be comparatively small.

Skipton.—Notice has been received by the Urban District Council from two companies that they proposed seeking powers in the ensuing session of Parliament for the supply of electric lighting in Skipton. The Council has now decided, in accordance with a promise made to the ratepayers during the recent gasworks controversy, that the time has arrived when a Bill should be promoted in Parliament empowering the Council to manufacture and supply electricity within the township.

Rugby.—At the last meeting of the Urban District Council, a letter was read from the Northern Counties Electricity Supply Company with regard to an electric supply for Rugby, suggesting that representatives of the Council should meet members of the company and exchange views with them. The Clerk said he had replied referring the company to the advertisements the Council had inserted in certain papers, stating that the Council were prepared to receive tenders for leasing their powers.

Blackburn.—At last week's meeting of the Town Council the Parliamentary Committee resolved that, in view of powers being obtained by the Corporation by the Bill to be promoted in the next session of Parliament for the extension of the area of supply for electricity purposes, it be an instruction to the town clerk to serve formal notice upon the local authorities of the following districts—namely, Livesey, Witton, Wilpshire, Pleasington, and Rishton—of the intention of the Corporation to apply for such powers in accordance with the provisions of the Electric Lighting Act, 1882.

Trowbridge.—Mr. D. Stevenson has been asked to inspect the town and prepare a report giving information as to the system of lighting most suitable, to report on suggested sites, the first cost of work, probable cost of maintenance and income, the most suitable area to commence with, and the question of refuse destruction. Edmundson's Electricity Corporation, Limited, have given the formal statutory notice on behalf of the Urban Electric Supply Company, Limited, that they intend to apply to the Board of Trade for a provisional order for electric lighting in the urban district of Trowbridge, for confirmation in the parliamentary session of 1901.

Cardiff.—At a recent meeting of the Electrical and Lighting Committee of the Cardiff Corporation, Mr. H. J. Burstall, the expert appointed in connection with the recent action, the Corporation *v.* Ferranti, to inspect the engine (300 kw. Ferranti alternator), reported that the alternator at the electricity works had been finished and adjusted to his entire satisfaction, the engine and the whole of the work decided to be done under the terms of settlement having been carried out. The engine was ready to be taken over by the Corporation. Mr. Appelbee, the resident engineer, said the engine worked well and satisfactorily, and could be taken over now. The committee thereupon decided to do so.

Hastings.—The Town Council have agreed to the extension of several mains at a total cost of £1,232. 9s. 7d., which is to be raised by loan. To effect a saving in the electric light works, it has been resolved to discontinue the Waterworks-road station and to remove a part of the plant to the East-street station. The remainder of the plant is to be disposed of. The balance-sheet in connection with the electricity department for the year ended Dec. 31 last was presented at last week's Council meeting. In moving its adoption, Councillor Dr. Alfrey said, although they paid rather a large sum for works, he was glad to say they had £200 or £300 to the good, notwithstanding that they had reduced the price, while coal had advanced in price.

Sheffield.—The city surveyor has reported to the Electric Light Committee that he has now taken out and removed the whole of the concrete foundation for the new alternator at the electric light works, and has found the work to be of a worse character than he had anticipated, and that consequently the action of the committee in ordering the work to be taken out and removed has been justified by subsequent events. Mr. S. E. Fedden is to be appointed chief engineer and manager of the electric supply department, and to be solely responsible to the committee for the same. The wiring and fittings department and trading department and factory will remain under the commercial manager, who is to be the head of the clerical staff, under the direction of the chief engineer and manager.

Walsall.—The electric mains are to be extended from the generating station along the Pleck road as far as Bescot, and two transformers provided, at a total estimated cost of £5,178. A communication having been received from the Local Government Board stating that they proposed to defer sanctioning the loan of £15,000 until the sites for the proposed transformer stations have been decided upon, the Electric Lighting Committee have urged them to sanction the loan immediately, as it was impossible for the Corporation to fix at this date the situation of the transformer stations, and have pointed out that the site depends upon the

Digitized by Google

demand there is for the current, and that the delay in carrying out the new works is likely to seriously interfere with the Corporation complying with their statutory obligation to supply current.

Brighton.—At a recent meeting of the Town Council it was stated, with regard to the demand for arc lamps, that the committee received continual applications from various districts for small sections to be lighted with the arc lamps, and they were all given the same reply—viz., that it was not deemed advisable to grant the request at present. The present system of incandescent lights was so satisfactory that the committee did not consider it expedient yet to make any change. Upon an enquiry why the committee were accepting a tender for the supply of incandescent lamps at 1s. 3¾d. per lamp, when they had tenders at 6d. and 9d., it was explained that the lamps were subjected to certain tests, and it was found that the more expensive lamps gave the required results more economically than the cheap makes, and were beyond question the cheapest.

Walton-on-Naze.—The electric light has made great progress during the last two years. Messrs. G. E. Taylor and Co., of Lombard House, George-yard, E.C., electrical engineers, were the contractors for the electric work recently done at the pavilion, as also for the further preparation for electric lighting and cooking at the Café Chantant. A number of 16-c.p. and 32-c.p. lamps are fixed on the stage and the auditorium. At each side of the stage provision has been made for use in the wings for one plug of 200 c.p. for stage effects. All the offices are lighted by electricity, as also the staircase. The lighting of the outside includes two lamps at each end of 16 c.p. each. At each of the four corners are three-light brackets for 32-c.p. lamps, a total of 384 c.p. for the illumination of these corners. The system of wiring is lead-covered twin wire, which is arranged so that there shall not be joints in any circuit. All the brackets, which are of pretty design, are of copper. The consulting engineer has been Mr. G. L. Addenbrooke, and Mr. H. Dawkins, the representative of the contractors, has had charge of the whole of the contract and works.

Beckenham.—The Electric Lighting Committee's report, adopted at the last meeting of the Urban District Council, contained the following items: "A letter from the Local Government Board sanctioning a loan of £7,000, repayable in 10 years, for the wiring of houses was submitted. Instructions were given to the engineer to prepare a form of specification and tender. A telegram was submitted from the British Insulated Wire Company, Limited, agreeing to the scheme of free wiring set out in the Council's memorandum of April 25, 1900. The clerk was directed to prepare a supplementary contract embodying the free-wiring arrangement and other matters. The officers were instructed to draft a form of circular to enable the contractors to proceed with the canvassing of householders. The committee recommend that in connection with the loan for free wiring, Mr. Reginald P. Wilson, consulting electrical engineer, be retained to supervise and be responsible for the proper execution of the wiring, and that he, in conjunction with the surveyor, be instructed to prepare the necessary specifications, and obtain tenders for the wiring. The engineer was instructed to prepare specifications and invite tenders for transformer stations."

New Companies.—The following new companies have been registered: Premier Electric Lamp Company, Limited, with a capital of £100,000 in £1 shares, the object being to acquire the business of the old company of the same name and extend the same, and to carry on the general business of an electric light and power company, etc.—South Lancashire Electric Supply Company, Limited, with a capital of £10,000 in £1 shares, the object being to carry on in South Lancashire or elsewhere the business of electricians and suppliers of electricity for the purposes of light, heat, motive power, and otherwise.—Lewisham and District Electric Supply Company, Limited, with a capital of £10,000 in £1 shares, the object being to carry on at Lewisham, S.E., and elsewhere the business of an electric light company in all its branches.—Improved Electric Glow Lamp Company, Limited, with a capital of £40,000 in £1 shares, the object being to carry on the business of electrical engineers, etc.—Dow Portable Electric Light and Power Syndicate, Limited, with a capital of £40,000 in £1 shares, the object being to adopt an agreement with a company of the same name for the acquisition of certain inventions relating to galvanic batteries, and to carry on the business of electrical engineers, suppliers of electricity, etc.

Dalkeith.—In connection with the scheme adopted, subject to the revision of details, for the electric lighting of Dalkeith by a London firm of engineers, the three Commissioners who at the last meeting voted against the matter being carried further for the present, have obtained a report by Mr. W. A. Bryson, electrical engineer, Leith. The three Commissioners referred to mention that the town of Dalkeith has streets which extend altogether to about six miles, exclusive of courts and closes. They are at present lighted by 300 ordinary and 20 incandescent gas lamps, and the average cost for gas for the past five years has been £210, and, in addition, the maintenance and expense of lighting has cost £106 per annum. The price charged by the Dalkeith Gaslight Company, Limited, to the Commissioners for the purposes named is 3s. 7d. per 1,000 cubic feet. The cost for electricity is to be 3d. per unit, and to include all charges. Mr. Bryson, as a result of careful examination, states that, while arc-lamp lighting would be suitable for the main streets, in the narrow ones, which are numerous, much of the light would be wasted. Incandescent electric lighting may be used, but it has a less penetrating power than gas. He calculates that if the Commissioners were to extend the system of incandescent gas lighting of 60 c.p., the cost would be found considerably less than electric lighting. A possible estimate for the consumption of gas by 225 lamps lighted till 11 p.m., and 50 burning all night, might be put at £440, this allowing for lighting and maintenance. If the streets were to be lighted throughout by means of incandescent electric lamps of 32 c.p., the cost at 3d. per unit, based on the same hours in use as the gas, would, he states, be £637. The Commissioners are to have a communication before them at the next meeting from the engineers as to the obtaining of the provisional order.

Manchester.—The electricity department of the Manchester Corporation, which includes Manchester, Withington, Moss Side, and Levenshulme, have issued the annual financial statement for the year ended March 31 last. The report of its working is signed by Mr. Alderman Lloyd Higginbottom. The committee state that the total quantity of electricity measured and accounted for amounted to 6,468,405 units, an increase of 24 per cent. over the previous year. The consumers numbered 3,240, an increase of 670. Additional mains were laid to the extent of 47 miles 530 yards, making the total length laid 110 miles 45 yards. Revenue derived from sales of current, etc. (which works out at 3·20d. per unit accounted for), amounted to £86,297. 18s. 4d., and the working expenditure to £49,905. 11s. 6d., showing a gross profit of £36,392. 6s. 10d. From this sum is deducted an amount of £27,199. 15s. 5d. on account of interest on mortgage debt, etc., and sinking fund, and a net profit is shown of £9,192. 11s. 5d. This surplus, together with the balance of £2,000 brought from last year's account and £572. 6s. 5d. interest on reserve fund investment, making a total of £11,764. 17s. 10d., has been appropriated in the following manner: paid to city fund in aid of rates, £10,000; placed to reserve fund, £1,764. 17s. 10d. The following statement exhibits the financial position of the undertaking at March 31: total capital expenditure, £641,821. 18s.; mortgage debt, £556,278. 9s.; amount of mortgages redeemed to date by action of sinking fund, £49,232. 11s.; balance at credit of renewals suspense account, £335. 4s. 5d.; ditto reserve fund, £13,360. 15s. 2d. Owing to the necessity for renewing a considerable length of mains which had proved defective, the charge upon revenue account for repairs and renewals of mains this year amounted to £7,453. 10s. 6d., as against £1,495. 12s. 6d. last year. In addition to this, the sum of £12,459. 10s. 6d. had been taken from the renewals suspense account to cover similar expenditure. The committee regretted that the accident which happened to the machinery at Dickinson-street station in September last did considerable damage. The amount withdrawn from the reserve fund on account of the breakdown was £7,069. 18s. 1d. The committee are putting forward the equipment of Bloom-street station in order to meet the increasing demand for the supply of electrical energy, and to be ready to supply the current necessary for working the tramcars. At the Polygon, Ardwick, satisfactory progress is being made, it is stated, with the erection of buildings for workshops and cable stores, and it is expected they will be ready for occupation before the end of the present year. Plans have been approved for the equipment of a part of Stuart-street generating station. Considerable progress has been made during the past year with the laying of electric mains in the districts of Withington, Moss Side, and Levenshulme. The supply of current has been available in portions of Moss Side since December last, and in Withington since February last. The committee add that on Sept. 30 last the price of electric energy to long-hour consumers was reduced from 1½d. to 1¼d. per unit, and a similar reduction was made in the price of current supplied for motor purposes. The foregoing represents, they state, a concession to the consumers of £2,873. 8s. 6d. in six months.

Sunderland.—The report of Mr. J. F. C. Snell, the borough electrical engineer, on the electric light undertaking, states that during the past year there has been an increase in the number of lamps connected and in the amount of electricity consumed, as well as a notable advance in the annual profit. On March 31 last year there were 25,617 lamps connected, and this had grown by the March of this year to 35,024 lamps, an increase of 36 per cent. The number of units sold had leaped from 472,343 for 1899 to 640,079 for the later period, representing an increase of 35 per cent. The gross profits on the undertaking were £4,047. 6s. 4d., and after meeting the sinking fund and interest, which cost £3,580. 10s. 9d., there was a net profit of £466. 15s. 7d. left. This compares with a gross profit for the previous year of £2,865. 17s. 9d., and a net profit of £364. 11s. 3d. The report states that the profits were equal to 5½ per cent. on the average capital outlay for the year. The enormous rise in the price of coal made an increase of over 50 per cent. in that item alone, but for which there would have been a clear profit of over £1,100. The report continues: "The actual capital outlay on the undertaking to March 31 last is as follows: buildings, £10,329; machinery, £38,983; mains and services, etc., £29,706; professional services and incidentals, £1,894; public arc lamps, £2,000—total, £82,912, representing £74 per kilowatt installed. The average of all other municipal stations, as extracted from the Board of Trade returns, 1900, is £84. Extensions are now proceeding at Dunning-street, which, when completed, will use up the whole of that site, increasing the kilowatts installed to 1,980, or 3,600 i.h.p., which will bring up the capital outlay to the amount sanctioned—namely, £111,100, or £56 per kilowatt installed." The report states that seven section pillars have been fixed, whereby the risk of breakdowns of the mains is very much reduced and faults will be more quickly localised. Mr. Snell emphasises the necessity for immediate extension of the works, and says: "Four 120-i.h.p. steam dynamos for lighting and traction, with surface condensers, and four Galloway boilers with economisers, mechanical stokers, and induced-draught fans, and a tramway switchboard, are now being fixed. A new site has been negotiated for on which the new (and future principal) Hylton-road station will be erected. This site is well

Digitized by Google

placed as regards centrality, coaling arrangements, and ample room for extension, as at least 15,000 h.p. can be placed there. It will be necessary to at once lay down a certain portion of this plant to cope with the increasing demands for current. The limit of supply from Dunning-street is 55,000 8-c.p. lamps (including the plant for tramways), and already, adding lamps applied for to those connected to the station, there is a total of 46,000, emphasising this immediate necessity for further addition. The department is now supplying power for all kinds of industrial purposes, graving-dock pumps, dock cranes, large workshop tools of all descriptions, mortar mills, joiners' tools, stable machinery, elevators, printing machinery, sewing machines, coffee mills, and other machinery, even revolving hairbrushes." As to the cost per unit, it is satisfactory to note that Sunderland is seventh on the list of similar undertakings, and only ·57d. per unit more than the lowest—Edinburgh, the price being 2·90d., compared with Sunderland's 3·58d. per unit. Mr. Snell states that there is an efficiency of 85·78 per cent. at the station, and the machinery is in the highest condition. Mr. Snell bears warm testimony to the excellent services of the staff.

Bury.—The annual report for the year ending March 31, 1900, of Mr. S. J. Watson, borough electrical engineer, states that the total number of consumers connected with the electricity works on March 31 last was 198, with 14,733 8-c.p. lamps, as against 144 consumers, with 10,275 lamps at the end of March, 1899. The number of units sold during the year ending March 31 was 213,395, as against 115,853 for the previous year, and 64,462 for the year ending March 31, 1898. "A satisfactory improvement," says the report, "is shown by the load factor, which for the past year works out at 12½ per cent., thus indicating that the maximum load was used for three hours per day, as compared with 9 per cent., or 2 hours 12 minutes, for the previous year, and 8 per cent., or 1 hour 56 minutes, for the year ending March, 1898. This improvement is partly due to the extended use of the arc lamps for street-lighting, and partly to the maximum demand tariff, which encourages the long-hour consumer. Without the public lighting the value would be 11 per cent., or 2 hours 36 minutes per day." Some important extensions at the works have been made during the year, including the putting in of a Lancashire boiler, 30ft. by 7ft., made by Mr. Wm. Lord, of Bury, a 360-b.h.p. engine, direct coupled to a 250-kw. dynamo, to run at a speed of 370 to 400 revolutions per minute, and a balancer and booster set. The number of cells has been increased from 130 to 260. An agreement for the maintenance of these cells for three years has also been arranged. The present capacity of the plant, after making an allowance for spares, is 7,300 8-c.p. lamps alight at once. This is equal to nearly 15,000 8-c.p. lamps connected to the mains, as only 50 per cent. of the lamps connected are usually used at once. When the second large generating set is delivered the capacity will be increased to 14,600 8 c.p. lamps alight at once, or nearly 30,000 8-c.p. lamps connected to the mains. During the past year 2,270 yards of cables have been laid in the streets, and the total length of cables laid to date equals 9 miles 376 yards. There are now 31 arc lamps erected in the main streets, 13 additional lamps having been set to work during the past year. It has also been decided to erect two more in Manchester-road, by the fountain at Buckley Wells. The analysis of cost for the past year gives the following figures: generating costs, £1,595, equal to 1·79d. per unit; interest and sinking fund, £1,803, equal to 2·03d. per unit; total cost, £3,398, equal to 3·82d. per unit; profit, £184, equal to ·21d. per unit; revenue, £3,582, equal to 4·03d. per unit. Last year there was a deficit of £336, and the previous year of £579. The cost of carbons and attendance to public lamps have this year been deducted from the revenue received for public lighting, as Mr. Watson considers it misleading to express the same as a cost of generation or source of revenue in any way depending on the units sold for all purposes. An additional expenditure of £135 has been necessary on account of the advance in price of fuel, the average price paid during the past 12 months being 9s. 6½d. per ton, as compared with 6s. 11d. per ton for the previous year. The question of making any immediate reduction in the charges will require careful consideration, having in view the cost of renewing some of the vulcanised rubber-insulated cables, which have to be met by revenue. Mr. Watson has, therefore, prepared estimates to see whether any reduction can safely be made without causing a deficit at the end of the year, and recommended that the present tariff be maintained to Dec. 31 next, and if the progress made by that date were sufficiently satisfactory a reduction may be made to date from Jan. 1, 1901. Such an alteration would only reduce the revenue for the year by about £75, and there should still be a margin on the profit side to meet any unforeseen expenditure.

PROVISIONAL PATENTS, 1900.

JULY 2.

11897. Improvements in trolleys for overhead electrically-driven tramcars. James Townsley Pearson, St. James's Hall, Burnley.

11907. An improved block or mounting for electrical, gas, and like fittings. John Bolton, 287, Lillie-road, Fulham, London.

11914. Improvements in the manufacture of electrodes for secondary batteries. James Charles Richardson, 19, Claremont-square, London.

11917. Improved method of and means for signalling, chiefly designed for submarine purposes. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Gray Telephone Company, United States.) (Complete specification.)

11929. Improvements in or relating to production of type by means of electric current. Frank Charles Frederick Knaak and James Smalley Campbell, 11, Pall-mall, London.

11933. Improvements relating to the regulation of electric motors. Robert Lundell, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

11937. Improvements in telephone systems. Frans Birger Stafsing and Carl Egnér, 322, High Holborn, London.

11941. Improvements in electric motors and regulating appliances for turret turning, gun training, and analogous purposes. William Harding Scott, 47, Lincoln's-inn-fields, London.

11944. Switching arrangement for Nernst and vacuum incandescence lamps. Victor Fallon Feeny, 66, Queen Victoria-street, London. (Allgemeine Elektricitäts-Gesellschaft, Germany.) (Complete specification.)

JULY 3.

11965. Improvements in electric receivers and electric clocks. Archibald Barr, William Stroud, and Ludwig Becker, 154, St. Vincent-street, Glasgow.

11970. Improvements in or relating to the construction of electric switches and contact makers used for electric tramways and the like. John Milnes, 4, St. Ann's-square, Manchester.

11991. Improvements in rheostats for electric motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (John L. Hall, United States.) (Complete specification.)

11997. An improvement in accumulators or secondary batteries. Richard Rodrian, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

12002. Improvement for providing an automatic lock for the purpose of securing electric and other lamps in lampholders, electric and other shades in holders, and locking couplings of a like nature. Eric Philip Barfield, 8, Grosvenor-gardens, Muswell-hill, London.

12003. Improvements relating to dynamo-electric mine exploders or apparatus for firing explosives. Jasper Wetter, 37, Essex-street, Strand, London. (Louis Charles Gomant, France.) (Complete specification.)

12016. Improvements relating to electrically-propelled motor vehicles. Thomas Jefferson Ryan, 18, Buckingham-street, Strand, London. (Complete specification.)

12018. Improvements relating to electric propulsion for motor vehicles. Thomas Jefferson Ryan, 18, Buckingham-street, Strand, London. (Complete specification.)

JULY 4.

12054. The electric lighting of motor-driven vehicles. Percival Harry Frost Smith, 10, Basinghall-street, London.

12074. An improvement in static voltmeters. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Actien-Gesellschaft, Germany.)

12086. Improvements in electrical storage or secondary batteries. Arthur William Baxter and Charles Baxter, 53, West-hill, St. Leonards, Sussex.

12089. Improvements in dynamo-electric machinery. Charles Edward Grove, The Thames Ironworks, Orchard-yard, Blackwall, Middlesex.

12100. Improvements in or relating to electrical tramways and the like. Edward Bennett Viles, 322, High Holborn, London.

12111. Improvements in electrical jacquards and dobbies. Jan Szczepanik and Ludwig Kleinberg, 46, Lincoln's-inn-fields, London. (Complete specification.)

JULY 5.

12115. Improvement in apparatus for magnetically separating iron or steel borings, filings, and the like from brass or other non-magnetic substances. Benjamin Young, Leek-street, Birmingham.

12128. A device for shielding fallen wires from overhead electrical conductors. George Sockett Holmes, 10, St. Georges's-crescent, Liverpool.

12152. Improved method for the practical application of lead secondary batteries. Carl Heim, 63, High Holborn, London. (Complete specification.)

12160. Improvements in the manufacture of filaments for electric incandescence lamps. Victor Thomas, 53, Chancery-lane, London.

12170. Electric meter. Paul Mandowski, 40, Chancery-lane, London. (Complete specification.)

12175. Improvements in electrical relays. The Thomson-Davis Telephone System, Limited, and Arthur Thomas Milnor Thomson, 22, Southampton-buildings, Chancery-lane, London.

12177. Improvements in the holders of electrical incandescent or glow lamps. William Walker, jun., 7, Staple-inn, London.

12179. Improvements in or connected with electrical tramways or railways. Hugo Hirst, 47, Lincoln's-inn-fields, London.

JULY 6.

12249. Improvements relating to thermo-electric cells. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. Louis Siegfried Langville, United States.) (Complete specification.)

12256. Improvements in and relating to electric arc lamps. Curt Arthur Max Bärner, 322, High Holborn, London. (Complete specification.)

12267. Improvements in electric accumulator. Vladimir de Robinsky, 4, South-street, Finsbury, London.

JULY 7.

12276. Improvements in hooks or clips for gas and water pipes, electric wire conduits, picture rods, and the like. Cope, Allman, and Co., Limited, and William Allman, Icknield-square, Birmingham.

12296. Improved turbine fan or air propeller driven electrically or by mechanical power. Bridgman Russell, 42, Berwick-street, Oxford-street, London.

12315. Improvements relating to electrical signalling and communicating apparatus. Gregor Blanck, Joseph William Hudson, and William James Downs, 322, High Holborn, London.

12321. An improved collector for electrical machines and the like. Fritz Kaeferle, 6, Lord street, Liverpool. (Complete specification.)

12331. Improvements in blocks for electric conduits. Eugen Schellbach, 45, Southampton-buildings, Chancery-lane, London.

12338. Improvements in dynamometers and/or brakes. John Herbert St. Hill Mawdsley, Norfolk House, Norfolk-street, Strand, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on July 23.

1899.

9436. Electric telegraphic apparatus. Cantono. (Date applied for under International Convention, Jan. 12, 1899.)

9437. Electric telegraphic apparatus. Cantono. (Date applied for under International Convention, April 13, 1899.)

13733. Electric traction on a read-contact or like system. Thompson and Walker.

13939. Magneto-electric and dynamo-electric generators. Frank Bryan and Abel Henry Bayley.

15744. Electric regulating switches. Lucas.

15907. Terminals of electric batteries and the like. Wright.

16285. Plugs for telephone switchboards. Pearmain.

16444. Method of receiving telegraph signals as displayed or photographed by magnetically-deflected cathode rays. Siemens Bros. and Co., Limited. (Siemens und Halske Aktiengesellschaft.)

Digitized by Google

NOTES.

Institution of Junior Engineers.—On Friday next, June 27, the members of the above institution propose to visit the generating station and depôt of the Central London Railway at Shepherd's Bush. The time fixed for the inspection is 6.30.

Society of Chemical Industry.—This society has been holding its meetings in London this week at the Royal Institution. Prof. Chandler is president this year, and delivered a most excellent address. Amongst the places of interest which the society visited was the Shoreditch refuse destructor.

Congress on Physics.—We will remind our readers that the International Congress on Physics is to take place in Paris next month. The meetings will commence on Aug. 6 and continue till the 11th. Sixty interesting papers have already been put down for discussion, so that members of the congress are expected to work hard. The very short interval between the closing of this congress and the meeting of that on electrical subjects will enable both to be attended without inconvenience.

Overhead Wires.—The Cork Electric Lighting Company has asked the permission of the Corporation to a proposal to supply electric light in the outlying districts of Cork by means of overhead wires. The city engineer reports practically in favour of the proposal, but more details are to be given to the Corporation before the matter is decided. The company's reason is that the lower capital charge enables light to be supplied more cheaply. This seems to us to be a valid consideration in certain scattered districts.

Personal.—We are pleased to note that Mr. Thomas Carter has been appointed demonstrator and assistant professor in electrical engineering in the Heriot-Watt Technical College, Edinburgh. Mr. Carter is an old student of this college, and since leaving it has obtained extensive practical training. This he has recently supplemented by a systematic study of electrical engineering in Germany and Switzerland. It is encouraging to note that the Heriot-Watt recognise the advantage of practical experience.

Society of Model Engineers.—The fourth monthly meeting of the Liverpool branch of the Society of Model Engineers was held at the Balfour Institute on July 4, when a very fine collection of models was on view, and Mr. Hastings gave an interesting description of the engine for his new model torpedo-boat. The next meeting will be held in the recreation-room at the Balfour Institute, Smithdown-road, Liverpool, on Aug. 1 at 7.45 p.m., when another exhibition of models will take place, and there will be a general discussion on any difficulties experienced by members in connection with their work.

Wireless Telegraphy.—General Greeley is the authority for the statement that the Signal Corps have established wireless telegraphy stations, and are now successfully operating a system of wireless telegraphy between Alcatraz Island, San Francisco, and Fort Mason. It has been impossible previously to obtain cable communication between these two points owing to the interruption from shipping. It is also stated that a similar system is to be used to bridge the Magellan Straits in order that communication may be obtained between the mainland of the Chilian republic and the outlying island.

American Tramways.—The data respecting the growth of American tramways is so largely quoted that we shall be glad when the English lines will afford statistics of a similar nature, in order that the signs of progress in electric traction need not always be supplemented with American figures. We are told by one of the American authorities that at the end of last year there were about 19,000 miles of street railways in the States under 870 distinct managements. The total capital of these companies amounts to no less than £360,000,000. We believe that the shares in these undertakings are, as a rule, worth more than their par value.

Combined Lighting and Traction.—The officials of the Evanstone Electric Street Railway of Chicago have decided that the combination of electric lighting and electric traction in the one street is to be deprecated. Owing to their cars leaving the tracks so frequently, these officials have held an expert examination into the cause, and have decided that it is due to the large number of insects killed by the electric lamps beside the track. We should require to see that bank balance of the company, and also a certificate, under penalty, as to the veracity of its officials, before we tried to believe the explanation in question.

A Cable to China.—We understand from a Reuter's telegram that the Powers are considering the laying of a new cable between the present seat of disturbance or base of operations in China and some points such as Shanghai, Port Arthur, or Yokohama, through which more speedy communication could be had with Europe. According to the present tentative arrangements the expense of the undertaking will be borne jointly by the Powers. It is probable that the United States will be able to lay the cable in the shortest time, owing to the fact that a cable which is intended for inter-island communication in the Philippines could be diverted to China.

The Joint Paris Conference.—The following is the subject on which discussion is to take place at the joint meetings of the Institutions of Electrical Engineers of this country and America—*i.e*, "The relative advantages of alternate and continuous current for a general supply of electricity, especially with regard to interference with other interests." We understand it is specially desired to discuss how far interference with other undertakings, rather than ordinary commercial and industrial conditions, will come to be a determining factor in the selection between continuous and alternating currents. The joint meeting will be held on Aug. 16 in the American Pavilion in the Exhibition.

St. Johns, Newfoundland.—We gather from the *Scientific American* that a new electric railway has been opened in St. Johns, Newfoundland. There are seven miles of track and 20 cars. As the traffic increases the line will be extended to the suburbs. The current is generated nine miles from St. Johns. There is a chain of four lakes, and from the outlet of the last runs a flume which is built along a steep hillside for 3,300ft. until it disappears in a tunnel cut 350ft. through a bluff of solid rock. At the end of the tunnel was erected a huge sluice box of timber, to the bottom of which is fixed a steel tube 6ft. in diameter. Through this the water flows 185ft. to the power-house. The capacity of the plant is 1,600 h.p., but the flume is of sufficient capacity to drive another plant of the same size.

North-East Coast Institution.—We have received parts V. and VI. of vol. LVI. of the *Transactions* of the above institution, which contain, among other things, the paper by Mr. Borrowman on "Some Considerations affecting the Training of Young Engineers." In this the author expresses the regret that the old apprenticeship system has died out. He urges the combination of theoretical training with that practical experience which alone is given to

Digitized by Google

apprentices nowadays, and points out that special experience in one department is now more essential than an all-round smattering of many subjects. Mr. Borrowman's paper is worthy of most careful study. The discussion also is of great value. On the whole we gather that the speakers advocated a certain amount of practical training preceding the theoretical.

The American Association of Science.—The above association for the advancement of science, which is run somewhat on the same lines as our British Association for the same object, had a most successful meeting in New York the last week in June. The arrangement of the meeting so early in the year was in order that it might not clash with the various congresses which are being held in this country and in Paris. A certain amount of heat was added to the meeting by the determination of one speaker to introduce politics into the discussion. This gentleman, as a scientific man, objected to the United States Government spending 30 millions for the killing off of the Filipinos. We wonder if this gentleman, after the dreadful news which has arrived from China this week, would object to an expenditure of a similar amount towards the wiping of Pekin off the face of the earth.

The Pacific Cable.—The question of the Pacific cable was again brought up in the House of Commons on Thursday week, when Sir Edward Sassoon enquired as to how the matter was progressing. Mr. Chamberlain, in reply, gave the satisfactory information that the various Governments interested had accepted the recommendations of the Pacific Cable Committee, and that tenders for the laying of the cable would be called for forthwith. With this information one may reasonably hope that at no very far distant date an all-British cable communication between Great Britain and her Colonies will be an established fact. We are sorry to note, however, that Mr. Chamberlain could give no definite information as to the reduction of the telegraphic rates to India. This reduction is urgently needed, and it is hardly fair that while the rate to Australia is 4s. per word, it should be the same to India, which is only half the distance.

Power Bills.—On Monday last the House of Commons agreed to the third reading of the County of Durham Electric Power Supply Bill, the Lancashire Electric Power Bill, and the South Wales Electric Power Distribution Bill. The only opposition raised was by Mr. Galloway, of Manchester, who did not think that Standing Orders should be suspended in order to get the Bills through in a hurry. His argument seemed to be that because the committee had taken nine weeks over the Bills, they should be talked out of existence in the House, or finally, perhaps, reach the House of Lords too late for the present session. It was a great pity that Mr. Caraway had not come into contact with the terminals of a Wilmshurst machine before making his speech, as he would then have learnt that electricity is rather apt to be in a hurry. The Jarrow and Hebburn Electricity Supply Bill and the Hastings Tramway Bill were read for a third time in the House of Lords on Monday last.

Rival Illuminants.—We have often stated in our columns that when electricity is substituted for gas in works and buildings generally a saving in the cost of lighting is usually found at the end of the year. Our friends having to do with the gas industry naturally refuse to see this, and it is only when proof comes from an independent source that the truth is really brought home to them. Such an instance as this we noticed recently in connection with St. Luke's Vestry wharf. In this case the Wharf Committee reported that they had considered the question of the cost, etc., of the electric lighting at the wharf premises. The superintendent in his report estimated that the sum of £40 had been saved during the year by only the partial use of electricity. The committee in consideration of this recommended the Vestry to substitute electric light entirely for gas, and to arrange for a connection with the County of London and Brush Provincial Company's mains for use when the supply of electrical energy by the Vestry's plant was not available. This recommendation, as would naturally be expected, was carried.

Insulating Gloves.—A competition amongst inventors of protecting insulating gloves for electricians is being arranged by the Association des Industriels de France contre les Accidents du Travail, 3, rue de Lutèce, Paris. A prize of 1,000fr. (£40) may be adjudged by the special commission to the inventor of the best glove, or be divided amongst the competitors according to the merits of their invention. These gloves must ensure a sufficient protection to the hand and forearm, be strong, and not only resist electric pressure, but also any accidental perforations which might be caused, for instance, by copper wires sticking out; they must be easy to put on to any size of hand and allow the workman the free use of his fingers for executing his work. To qualify, two pairs of gloves and a descriptive note must reach the president before Dec. 31 of the present year. The gloves and descriptions will remain the property of the association, who reserve the right of publishing any of these latter. The idea is worthy of support, as nothing is more dangerous in a high-tension station than a glove of rubber when perforated.

Municipal and County Engineers.—Mr. C. H. Lowe, the surveyor of the Hampstead Vestry, is the new president of the above association. In his presidential address delivered yesterday he gave a most interesting *résumé* of the probable changes which would be introduced in the routine of metropolitan engineers by the Local Government Act of 1899. Another topic which occurred in the presidential address was that of electric lighting. After referring to the good work done in Hampstead in the municipalisation of the electric light, Mr. Lowe proceeded to discuss the question of the control of such undertakings. He did not agree that the engineer or surveyor to a council should have a quasi-control over the management of this department, owing to the vast amount of ordinary duty, which is quite enough to occupy one man's time. Mr. Lowe considered that such a department, requiring as it does a most perfect knowledge in all its branches, should be administered by an electrical engineer entirely independent of the municipal engineer. Mr. Lowe then expressed the hope that during his tenure of office Mr. Cottam, electrical engineer to the Hampstead Vestry, could favour the association with an account of the undertaking and an opportunity of inspecting the station.

Loss of Life by Lightning.—We gather from analysis by Mr. A. J. Henry in the monthly *Weather Review* of America, interesting details as to the loss of life by lightning during the year 1899. In the United States during that year 562 persons were killed outright and 820 received severe shocks. Mr. Henry has ascertained that 45 per cent. of the fatalities occurred in the open, 34 per cent. occurred in houses, and only 11 per cent. under trees. Fully a dozen persons were killed in the act of stripping clothes which had been hanging out to dry on a wire line. Further news respecting the treatment of persons who have been struck by lightning comes from Surgeon-Major Cahen, of the French army, who reports having witnessed during a storm an officer and his horse both struck by lightning. The horse died on the spot, the officer, who seemed

Digitized by Google

to all appearances to have shared the same fate, was subjected to artificial respiration simultaneously with rhythmic tractions of the tongue. After a few minutes he began to breathe, and at the end of half an hour he was out of danger. M. Cahen says that if assistance had not been rendered at once to the officer, respiration would not have been speedily re-established, and he would have been asphyxiated. He is of opinion that in most cases a fatal issue is caused by want of immediate succour.

To Electrical Students.—A circular letter has this week been addressed to the students of the Institution of Electrical Engineers informing them that the Council of the Institution proposes to grant £5 to each of 20 selected students to assist them to visit the electrical exhibits in the Paris Exhibition. Intending candidates must fill up and return an application form (issued with the circular) before 10 a.m. on Saturday, July 28. In the selection the Council will give preference, other things being equal, to those who, being still students of the Institution, have either, or both, read papers before the students' section, or been members of the committee of that section. The conditions of the grant are as follows: (1) The selected student shall spend at least six days in Paris, the visit to commence not earlier than Aug. 27. (2) He shall write an essay or a paper on the exhibits in a special section allotted to him, and shall send the paper to the secretary of the Institution before Nov. 15, 1800. (3) The paper submitted shall, like all other papers presented to the Institution, become the property of the institution; if approved by the Council it may be read at a meeting of the students' section, and, if so read, will be eligible for the usual Institution premiums offered for such papers. We consider the above a most excellent idea, and trust that there will be a keen competition for the honour of reporting the progress shown by the exhibits.

London United Tramways.—Mr. J. Clifton Robinson, the managing director of the above tramway company, has scored another victory. Thus, the House of Lords Committee presided over by the Earl of Rosse passed on Monday last the preamble of his Bill without reservation of any kind, and the whole of the extensive scheme in the West of London, embracing the important extensions to Heston, Isleworth, Twickenham, Teddington, Hampton, and Hampton Wick, will at once be proceeded with. The present lines are already equipped, and will shortly be opened for traffic. The only opposition was that of the Middlesex County Council and a few frontagers in the Richmond-road. The Middlesex County Council *locus* was limited again, as was the case before Sir U. Kay Shuttleworth's committee in the Commons, and the frontagers on the Richmond-road failed entirely to prove a case. It seems that the Middlesex County Council persevered in their opposition because they considered that they should be the tramway authority for the whole county. In this attempt to imitate the London County Council they have not been successful, which is, we think, to the advantage of the inhabitants of their district. We offer our congratulations to Mr. J. Clifton Robinson, who, like an Irishman, will soon be spoiling for more councils to fight.

Our American Guests.—Following close on the visit by American Civil Engineers to this country, comes the news that the members of the American Institute of Electrical Engineers, who will shortly start for the Paris congress, have decided to spend a few days in London on their way. Our Institution has accordingly arranged to extend hospitality to these American engineers. The programme as at present settled includes the following items: On Sunday, Aug. 12, a trip will be made on the Thames on electric launches. A luncheon will be given to the American guests at one of the riverside hotels. The next day a dinner will be given in London, and on both Monday and Tuesday, 13th and 14th prox., visits to works in and around London will be organised. It is hoped that ladies will be brought by members to the river trip, and also to the dinner. This innovation, as far as the dinner is concerned, is greatly to be commended. The price of the dinner tickets will be 25s., including wine, while the river trip will not cost more than two guineas. The actual cost depends on the numbers who are taking part, and also on the fact that the Americans will be the guests of those who attend. The Council of the Institution expresses the hope that a large number of members and ladies will meet to give the Americans a true British welcome. Members should send their names quickly to Mr. W. G. McMillan.

Electric Discharge in Gases.—The following is an abstract of a paper by Mr. W. Wien which appeared in the *Physische Zeitschrift*. The abstract is taken from *Science Abstracts*, and reads as follows: "The electric discharge in gases takes place partly by means of material particles which, moving with great velocities, are accelerated at first positively, then, by impacts against other particles, negatively. These conditions must give rise to a radiation of electromagnetic energy. The present investigation was undertaken to see whether this energy could be measured by the difference between the electric energy supplied to vacuum tubes and the heat produced in the tubes. The E.M.F. at the electrodes and the current were measured by volt and ampere meters, and the heat produced was measured by a Bunsen calorimeter. The following table, in which some of the results are reproduced, shows that within the limits of experimental error the electrical and heat energy are equal:

E.M.F. volts.	Current amperes $\times 10^6$.	Calories $\times 10^3$ calculated.	Calories $\times 10^3$ observed.
368	1,085	95·4	94·9
535	1,152	147	149
562	5,682	763	771
682	4,394	716	713
838	2,026	406	411
932	1,731	385	393
1,650	310	122	125

Zones in Wireless Telegraphy.—At a recent meeting of the Paris Academy of Science, M. D. Tommasi read a paper describing an appliance to prevent the interception and interruption of messages to which wireless telegraphy is exposed. The apparatus is based on the principle that the distance to which electrical waves can be transmitted varies as the distance between the two metallic spheres of the oscillator. It will therefore result, that in reasonably varying the interval which separates the two spheres—that is to say, in diminishing the length of the oscillatory spark—it will be possible to regulate pretty accurately the distance that the electrical waves will be able to travel to reach the receiving post of the line. This apparatus principally consists in combining the transmitter of the aerial line, called A, by a second transmitter, B, of which the manipulator, put in motion in any fashion, sends at random long and short messages which get mixed up with those of transmitter A, its oscillator being regulated so that the zone of action of the rays emitted by transmitter B extend to a distance slightly inferior to that which the oscillator of transmitter A has been regulated. In these conditions the electrical waves emitted by transmitters A and B, mix up one with another in such a way that any receiving apparatus placed in the zone of action of transmitter B can only receive a confusion of dots and dashes, from which it will be completely impossible to determine upon the

Digitized by Google

message sent by transmitter A. It will, therefore, only be possible to receive the messages from transmitter A out of the zone of action of transmitter B. The security will be all the larger that the zone of action of transmitter B will be placed nearer to that of transmitter A.

The Chadwick Trust.—In the *Journal* of the Society of Arts for the 13th inst. will be found a full report on the work done by the trustees in connection with the above trust, which is interesting reading, as in it the rules connected with the working of the same are fully given. We notice that amongst other useful purposes to which the funds left by Mr. Chadwick have been applied, is the appointing of an assistant professor or demonstrator to the professor of municipal engineering at the University College, London. Exceedingly valuable classes are now given on the above subject, and the extra assistance provided by this trust enables much more complete organisation to be established. After detailing other work done under the Chadwick Trust, mention is made of the Chadwick scholarship of £100, which is awarded for three consecutive years, subject to certain regulations. The first of these scholarships has been given to Mr. W. P. Gorvain, who also received the Chadwick medal. During the year he holds the scholarship Mr. Gorvain will spend his time in the works of Messrs. Hawthorne, Davy, and Co., of Leeds. The trustees have also awarded a gold medal and £100 in money to Staff-Sergeant O. W. Andrews, M.B., R.N., for work done in promoting the health of the men in the navy. In the scheme a further provision is made for giving medals to those local authorities who make the greatest strides in sanitary science.

The Electric Arc.—We notice in *Science Abstracts* for June an abstract of a paper contributed by Mr. L. Arons to the *Annalen der Physik und Chemie.* The abstract reads as follows: "For the study of the electric arc as influenced by the nature of the surrounding gas, metallic electrodes are to be preferred to carbon electrodes, as their composition is better defined and they do not give out the great quantities of strange gases which render experiments in different gases worthless in the case of carbon electrodes. The gases experimented with were nitrogen and hydrogen. In nitrogen, arcs were obtained between aluminium, cadmium, copper, iron, magnesium, platinum, and brass electrodes. Tin melted at once, and between silver electrodes no arc could be made to play in an atmosphere of nitrogen. This fact is all the more remarkable as silver yields a particularly brilliant arc in air. It is evidently connected with the difference of chemical affinity between the metal and the gas in the two cases. The author found that nitrides are formed of all the other metals, but not of silver. Aluminium electrodes are covered with a greyish-black crust, whose chemical properties identify it with the nitride discovered by Mallet. Brass electrodes acquire a copper colour, owing to the greater consumption of zinc. Copper and aluminium, which in nitrogen give very beautiful arcs, give practically none in hydrogen. Platinum, silver, iron, and lead require very strong currents. The best hydrogen arcs are obtained with cadmium, zinc, and magnesium."

Electric Lighting Orders. — In the House of Commons on Thursday week, Mr. Lough questioned Mr. Ritchie, the President of the Board of Trade, as to the reason why the Board of Trade insisted on all transfers of electric lighting orders to companies being in a standard form, and refused to allow variations required by local conditions, and also on what grounds they refused to allow the insertion of agreed provisions for the reduction of the maximum price either for public or private lighting, and whether he would consider the desirability of relaxing these departmental rules. In answering these questions for Mr. Ritchie, Mr. Hanbury said that the Board of Trade did not consider that deeds of transfer under electric lighting orders should contain any provisions other than those which were consequential on the substitution of a company for a local authority as undertakers. To go beyond this was to provide under the colour of a mere deed of transfer for matters which really required the approval of Parliament. Transferees were placed in exactly the same position with regard to price as they would have been had they obtained an order originally. The price for a public supply was left to agreement, or, failing agreement, to arbitration. The price for a private supply was not specifically fixed, but was left as in the order, subject to a maximum which might be revised periodically by the Board of Trade on the representation of the local authority. He could see no reason for altering the existing practice of the Department.

Electric Traction in Berlin.—In a contribution to a German railway journal on the question of electric traction for the Berlin local and suburban railways, Mr. Schubert advocates the greatest possible distribution of traffic. With ordinary locomotives he thinks this impossible, but with electric traction he considers that 180 trains could be dispatched per hour in each direction, as against the 12 per hour at present running. The service is apparently much of the same kind as that which we mentioned in a recent issue as being given on the Swansea and Mumbles railway, where trains with several carriages run at infrequent intervals, and are then almost empty. In the case of Berlin Mr. Schubert thinks that in place of the nearly empty trains of eight or ten carriages, with accommodation for 1,450 passengers, which run during the periods of minimum traffic, a single car affording accommodation for 75 passengers might be dispatched. Electric traction would further render the present railway capable of dealing with a daily average of 253,000 passengers, the present capacity in passengers carried being only 143,000 per diem. As to conversion, also, this might be easily accomplished. For the whole of the local and suburban lines 300 cars would be necessary, while the total cost of the equipment of the lines for electric traction would be about £450,000. He questions, however, whether it would not be advisable under the existing condition of things to entirely separate the local traffic from that of the suburban circular railway, and for the present introduce electric traction on to the inner lines only.

Accumulator Cars.—Mr. M. R. Zechlin in an article in the *Centralblätt fuer Accumulatoren und Elementenkunde* speaks of the possibility of improving accumulator cars. This, he thinks, can be done in two directions: first, by decreasing the weight of the cars; and, secondly, in the use of ball bearings. By reducing the weight, he states, the tractive resistance would also be diminished, as well as the effect produced by inequalities of the road surfaces on the structure of the cars and accumulators. This economy in weight might be obtained by the judicious employment of tubular construction without detriment to the strength and rigidity of the cars, and by paying greater attention to the dimensions required for a given strength. The weight of the car itself is, Mr. Zechlin points out, of vital importance, as a surplus weight in accumulators of from 20 to 50 per cent. of the total has to be carried. This surplus weight, however, ensures the necessary adhesion of the car wheels, and therefore the endeavour of the designer should be to produce a car which, together with its complement of accumulators, is of just sufficient weight to secure the requisite adhesion under given conditions with a proper distribution of the weight. Most of the accumulator cars constructed up to the present leave much to be desired in

Digitized by Google

the direction indicated. There is apparently little room for the further improvement of the driving motors and control of the same. Neither does there seem any immediate prospect of considerable economy being effected in the weight of accumulators. A further means of improvement also, says Mr. Zechlin, consists in increasing the diameter of the bearing wheels, whereby the tractive resistance of the car may be reduced and other advantages obtained. This does not, however, apply to all forms of motor-propelled vehicles.

The North-Western Electrical Association.—The summer convention of the North-Western Electrical Association of America was held this year at the Grand View Hotel, Waupaca, at the end of last month. President Norcross delivered an address, of which we feel bound to give the following extracts in order to show that in America they make orators of their electrical engineers. Speaking of the beauty of the district he said: "We have wandered over the hills and through the dales, and have been fascinated by the varied scenery; we have breathed the pure atmosphere, have quenched our thirst from the clear water of these gem-like lakes, until we are renewed by the zeal, vigour, and spirit of eternal youth. I have no doubt but that the Indian brave wooed his dusky bride in the sweet leafy retreats about these lovely lakes, and I am equally certain that his imperial successor, the white man, in these same cool, shady, enticing bowers has found courage to woo and win a fairer, sweeter maiden. It seems to me that the god of day wears a brighter smile of gladness as he brings a fresh morning to this enchanted valley, and I can easily believe that his departure over these western hills is accompanied by a benediction and a promise. Standing in the presence of so many beautiful and wonderful objects of Nature's handiwork, we may truthfully unite with the poet in saying:

> Know ye the land of the cedar and vine,
> Where the flowers ever blossom, the beams ever shine,
> Where the tints of the earth and the hues of the sky,
> In colour, though varied, in beauty may vie."

After this burst of eloquence it makes us long to be with the North-Western at their next summer meeting. In welcoming the members, the City Attorney said he had never seen such a set of jolly men in all his life, or so many fat men. The lean years of electrical engineers are evidently a thing of the past in America.

Electrolysis of Fused Salts.—The following is an abstract of a paper contributed by Mr. A. Helfenstein to the *Zeitschrift fuer anorganische Chemie*. The abstract appears in the *Journal* of the Chemical Society, and reads as follows: "The author has electrolysed the chlorides of lead, zinc, tin, cadmium, and silver, and lead bromide and iodide, and has studied the influence of varying conditions on the current yield. Neither in a V-tube, nor in any simple apparatus which allows direct contact of the anode and cathode liquids, can a decomposition be effected equal to that required by Faraday's law. Rise of temperature, decrease of current strength, decrease of the distance between the electrodes, and prolongation of the electrolysis have the effect of diminishing the current yield; in the case of lead iodide, however, the yield increases for a certain interval, 600deg. to 800deg., with rise of temperature, probably owing to the formation of periodide. The chief cause of the imperfect yields obtained is the solubility of the metal in its fused halogen compounds, and a consequent diffusion to the anode and to the surface of the electrolyte, where the metal is oxidised or goes off as vapour. Special experiments, in which a regulus of the metal was kept in contact with its fused halogen compound, showed that the solubility and rate of diffusion increase with rise of temperature. The diffusion of the halogen from the anode, although of less account than the diffusion of the metal from the cathode, is also responsible for a diminution of the yield; this influence of the halogen increases from chlorine to iodine. An approximately theoretical yield is obtained when the disturbing factors enumerated above are removed. The anode and cathode are separated from each other, either by being enclosed in tubes with lateral openings, or by the interposition of a diaphragm. As is to be expected, the enclosing of the cathode is much more essential than the enclosing of the anode. Further, the electrolyte is allowed to solidify on the surface, so as to prevent diffusion of metallic vapour into the atmosphere, and the temperature is kept as low as possible—just above the melting point of the salt. With these precautions, a yield is obtained which is independent of temperature, current strength, and duration of the experiment."

A New Mercury Interrupter.—We notice in the *Electrical Review* of New York a description by Mr. E. W. Caldwell of a new mercury interrupter, which he thinks has advantages over other mercury or liquid interrupters. It differs from most mercury interrupters in that the break is made between two surfaces of mercury instead of between a terminal of mercury and another of platinum or other metal; the air is completely excluded from the contact points, and, consequently, no oxidisation of the metal occurs on breaking; the break is made below the surface of the liquid, where the metal is clean, instead of at the surface, where the imperfectly conducting oxides and other impurities collect. In its simplest form the interrupter consists of a small soft rubber tube about a foot long, closed at each end with a steel plug, and filled with clean mercury, which makes contact with the two steel plugs. This tube is held in a vertical position, and the primary circuit of the induction coil is completed through the mercury column. When the middle of the tube is squeezed between the thumb and fingers, the mercury column is separated into two portions and the circuit is broken with astonishing suddenness and without any visible spark. This apparatus, though it will work well for a short time, is naturally only an experimental affair, and the rubber tube eventually becomes much deteriorated from chemical combination of its sulphur with the mercury. In another variety of the interrupter the separation of the two portions of mercury between which the circuit is broken is effected by a sort of poppet valve made of an insulating material. This valve can be operated automatically by an electromagnet in series with the primary circuit. Yet another form of the instrument, and one which is capable of giving very rapid interruptions, consists of a glass outer vessel containing an inner tube of insulating material. The inner tube is closed at the bottom by a flat plug, which is perforated with a small orifice. A disc of insulating material, perforated with a number of holes near its circumference, is arranged to revolve in close proximity to the lower end of the insulating tube, so as to open and close the orifice in the plug at the bottom. The outer vessel and the inner tube are partially filled with mercury, and electrodes of steel are placed in both. These electrodes are connected in series with the primary induction coil circuit, and when the disc is revolved it rapidly makes and breaks connection between the portions of mercury in the insulating tube and the outer vessel, and thus interrupts the current supply of the coil. The sharpness of the break produced by these mercury interrupters is said to be astonishing, and they work well with a much smaller condenser than is required by the ordinary vibrating or rotary break.

GLOUCESTER ELECTRICITY WORKS.

It is always interesting when an old town is progressive enough to walk in the van of modern progress to see how it has in years gone by carried on its municipal work. We this week record the opening of the electric light station at Gloucester, the latest development of the town's activity. So far back as in the ninth year of Edward III. the town was anxious about the paving of its streets, and was granted toll for seven years for this purpose. The toll was renewed for five years by Henry IV., and in the reign of Edward IV. an Act was passed to compel the inhabitants to pave the streets, and a year subsequently by charter the Corporation was empowered to do this work. Whether the obtaining of a pure water supply comes before or after the paving of the streets, we find that at Gloucester, as in so many other places, the obtaining of water was due to the forethought and the energy of the clergy. It was in 1438 that the Grey Friars granted that water might be brought from Robin Hood Hill for the use of the city. It was brought by an aqueduct at the centre of the street crossings. Lenaud says: "The beauty of the town lies in two crossing streets, and at the place of the middle meeting is an aqueduct incallated." This aqueduct remained till the reign of George II., when it was taken down, because, being situated in the centre of the four principal streets, it greatly interrupted the passage of carriages. Thus it will be seen that this city has had a long and interesting municipal career.

The electric light plant, which was officially viewed by the Mayor and Corporation yesterday and declared opened, is an example of the modern municipal enterprise of the citizens of Gloucester. The history of the electric light question in Gloucester dates from June, 1889, when four companies gave notice of their intention to apply to the Board of Trade for provisional orders authorising them to supply electricity within the district of the city of Gloucester. A report was then prepared explaining the various courses open to the Council, and it was decided not to consent to the application of any company, but to obtain further information, and consider whether or not the Council should itself apply for such a provisional order. Notices were given by three companies in 1890, by one company in 1891, and by two companies in 1894, but no further proceedings were taken by any of the companies. In 1895 one company again gave notice, and proposals were made by the City of Gloucester Tramways Company, Limited, for a combined scheme for electric lighting and traction. A deputation from the Corporation visited Bristol and inspected the electric lighting installation of the Corporation and the electric traction installation and the tramways of the Bristol Tramways Company. On Nov. 12, 1895, the Corporation decided not to consent to the application of any company, and resolved, with one dissentient, to apply for a provisional order authorising the Corporation to supply electricity for public and private purposes within the city, and the application was granted by the Gloucester Corporation Electric Supply Order, 1896, confirmed by the Electric Lighting Orders Confirmation (No. 1) Act, 1896. In February, 1897, a special committee was appointed to consider what steps should be taken under the order, and, on the recommendation of the committee, the Council in April, 1897, decided to exercise the powers given by the order, and began to look after a suitable site for the works. In June, 1897, the Council consulted Mr. Robert Hammond, M.I.C.E., and instructed him to prepare a preliminary report dealing generally with the question of

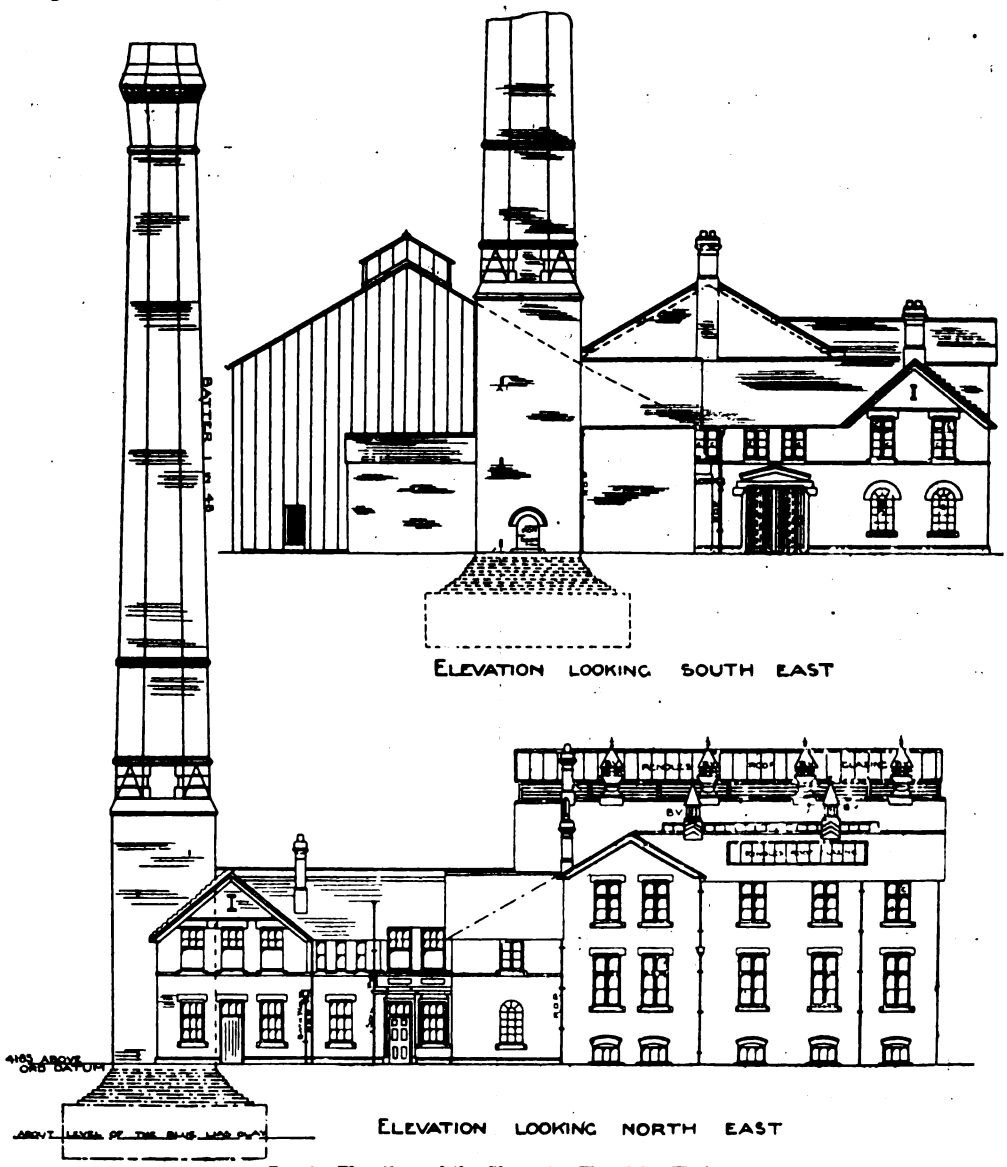

FIG. 1.—Elevations of the Gloucester Electricity Works.

Digitized by Google

electricity supply for lighting and other purposes, and with the question of providing a refuse destructor. In August, 1897, after considering Mr. Hammond's report, the Council unanimously decided to establish electricity supply works, with a refuse destructor in connection therewith, and engaged Mr. Hammond to prepare a scheme on the lines suggested in his report, and afterwards to prepare plans and specifications for and superintend the carrying out of the work. A sub-committee (accompanied by Mr. Hammond) visited the works at Cheltenham, Newport, Reading, St. Pancras, Islington, Leyton, Tunbridge Wells, Brighton, Shoreditch, St. James, Manchester, and Leeds. The sub-committee were thus enabled to verify much of the information given in Mr. Hammond's report; but they gave special attention to a number of points which the report left open for consideration—such as site, character of engines and plant, terms of supply, etc., and to financial and other matters, a knowledge of which might be useful in settling the details of the Gloucester scheme. The sub-committee thus obtained much valuable information, which was summarised in a report presented to the Council in October, 1897. Although the question of electricity supply was under consideration for a long time before the Corporation obtained and proceeded to carry out the powers given by the order of 1896, the time was not wasted, as it enabled the Corporation to ascertain and profit by the experience of other boroughs, and led to unanimous adoption of a really comprehensive scheme, which has met with the general approval of the citizens. At first much difficulty was experienced in finding a suitable site, but the question was happily solved by the Corporation purchasing the Bearland Estate and adjoining properties as an investment for corporate funds, and obtaining the sanction of the Local Government Board to use a portion of the property as a site for the electricity works. A most excellent site has thus been acquired in a central position, easy of access, and near to the river, canal, and dock branch railway. The Corporation have had an excellent adviser in Mr. Robert Hammond, and have been very fortunate in being able to let the whole of the works to contractors of the highest standing, although generally accepting the lowest tenders.

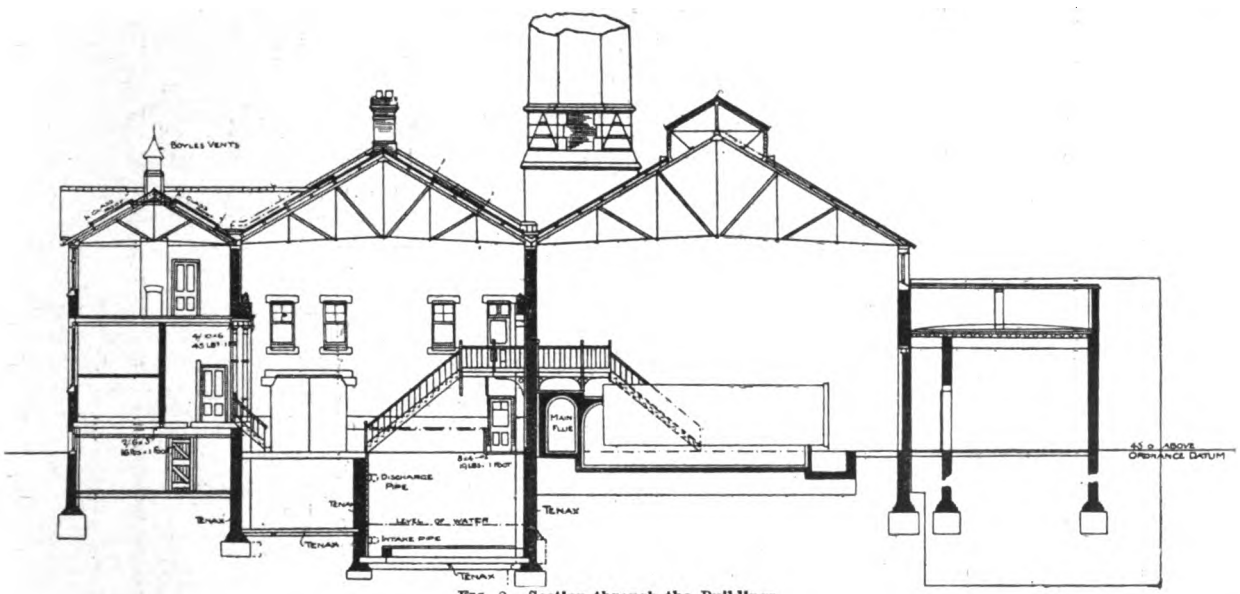

FIG. 2.—Section through the Buildings.

BUILDINGS.

The site of the generating works in the south-west part of the city has a pleasing historical interest. Situated within the south-west corner of the old Roman wall, it must have been, in times long gone by, the scene of many exciting incidents. The old wall from the South Gate passes through Kimbrose, down Commercial-road, turning through the yard of the electricity works, into and up Barbican-alley, and thence across the Bearland to the West Gate. Originally it was surrounded by a ditch and a rampart of earthwork, the rampart at this spot being of natural formation. On the ground now occupied by the Commercial Rooms was raised "an artificial mound towering high over all," the base of this probably extending over part of the site now occupied by the electricity works. This mound was the look-out of the ancient Britons, and from its summit a most extensive view across the river and vale and to the surrounding hills could be obtained. This mound, or "barbican," was in existence at the time of the siege of Gloucester in 1643, and was, no doubt, also utilised by the citizens as a "watch place" to observe the movements of the king's army, which then encompassed the city. Bearing in mind the historical associations of the site, it is interesting to find that during the work of excavation for the foundation of the chimney stack several large stones belonging to the old Roman wall was found. To place this discovery on record one of the stones has been re-worked, and the following inscription cut into it: "While excavating for the foundation of the chimney stack in May, 1899, this stone, which formed part of the old Roman wall of the city, was met with at 15ft. below the ground," and it has been built into the wall running opposite the front entrance to the works. Many small pieces of pottery, some few coins, and other things were also found; but a still more interesting discovery was made in the south-east part of the site, when digging the trenches for the foundation of the north-east wall of the switch and test rooms, the end of a large pit about 9ft. wide and 8ft. deep from top to bottom being come across. The walls of this pit were formed with very large oak beams, varying from 9in. to 15in. square, placed closely one on top of the other, making it perfectly solid, and on the outside clay puddling appears to have been put. The pit was perfectly full of animal bones of all descriptions, and in addition to this was found Roman snail shells, oyster shells, etc. Above the pit, and on the south-west corner of it, was a portion of a stone column, 12in. in diameter, which may probably have been part of a small temple once existing there. It is thought very probably that the pit before referred to may have been for the reception of the bodies of animals after being sacrificed upon an altar which stood near. Electricity works do not naturally lend themselves to elaborate architectural adornment, and it will be seen from Figs. 1 and 2 that no attempt has been made at unnecessary ornamentation, but the architect has, nevertheless, produced a structure which does credit to his profession. The whole of the building work has been carried out by the local firm of Messrs. John Gurney and Sons. The buildings are constructed of brick, with Bisley stone dressing, and in planning them care had to be taken to allow ample room for future extensions, and to plot them in such a way that the refuse destructor, for which contracts have been let, should form part of the same building. The natural formation of the site admirably adapts itself to what is required for the destructor. The buildings, which were designed by Mr. Harry A. Dancey, of Gloucester, consists of a lofty engine-room and boiler-house and a well-arranged suite of offices. The engine-room (Fig. 3) is 54ft. by 37ft. and 28ft. high.

Digitized by Google

The interior walls are executed in buff bricks, with a dado of brown glazed bricks, finished with a moulded capping. In the north-west corner of the engine-room is the condenser pit, the floor of which is 12ft. below the engine-room level. Running along the south side of the engine-room is the switch-room, and running behind this is the test-room. The level of these two rooms is 4ft. higher than the floor of the engine-room. This enables the switch board attendant to obtain a good view of all the machinery. The boiler-house runs parallel to the engine-room, and is of slightly larger dimensions. It provides space for four boilers, and also contains the pump-house and economiser. The chimney stack is 150ft. high, with an internal diameter which is nowhere less than 6ft. From the top of the stack a magnificent view may be obtained, and on the completion of the work the opportunity was taken to photograph the grand old cathedral.

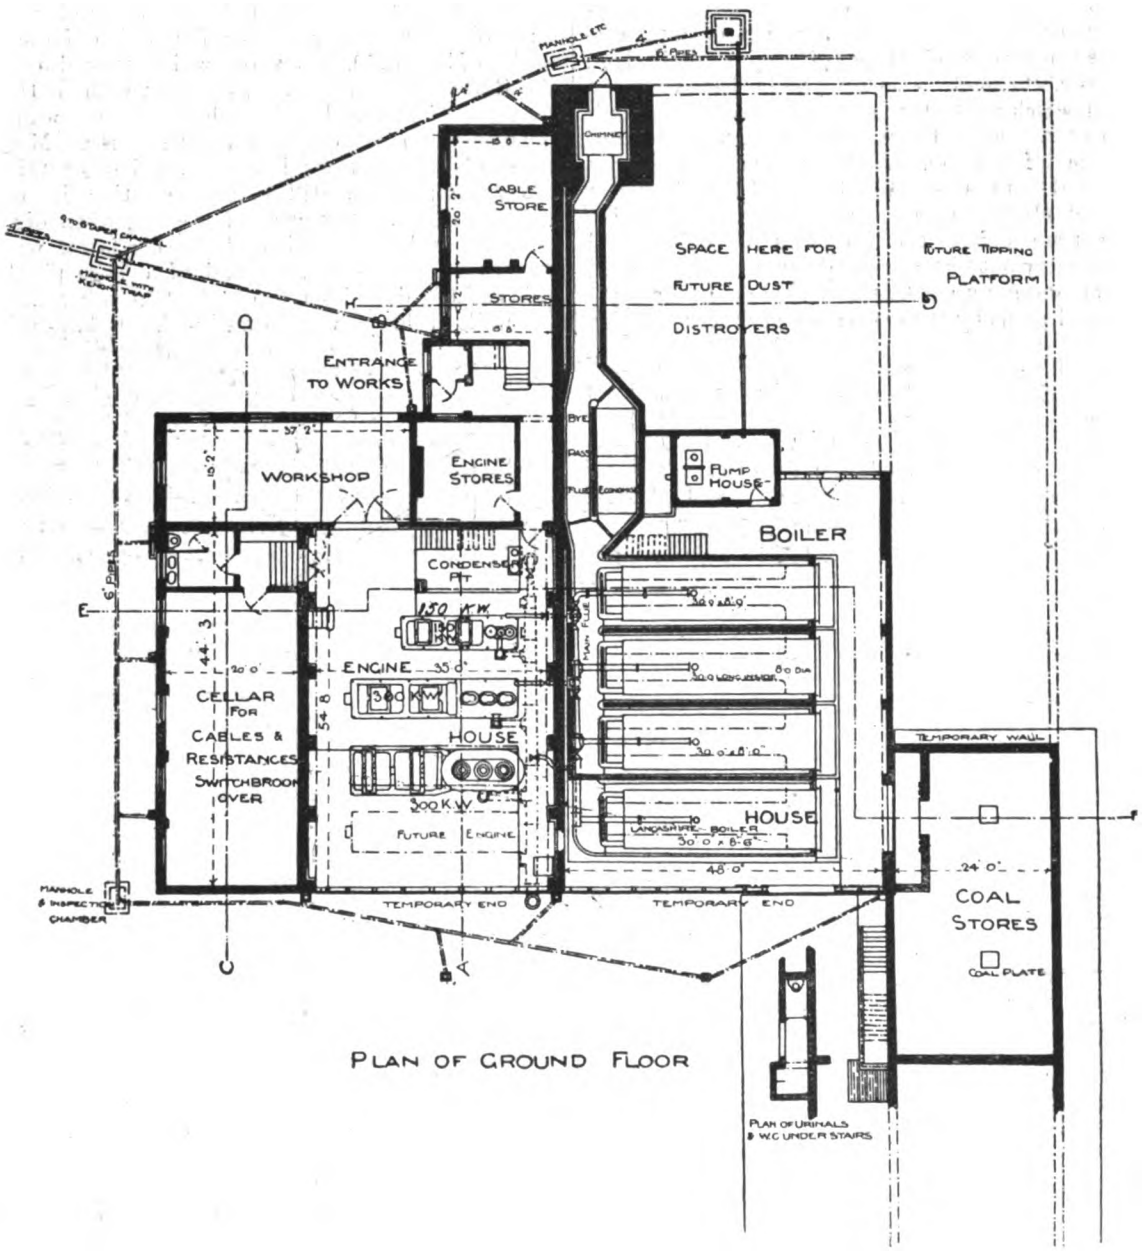

Fig. 3.—Plan of the Gloucester Electricity Works.

Steam Generating Plant.

The boiler-house (Fig. 4) contains three Lancashire boilers by Messrs. Yates and Thom, of Blackburn. Each boiler is 30ft. long by 8ft. in diameter. They are made of steel throughout, and are constructed for a working pressure of 160lb. per square inch. The shells are composed of seven rings, each made from one plate $\frac{13}{16}$in. thick. The boilers are fitted with Proctor's mechanical stokers. The dampers in the side flues are worked from the front end of the boilers, the balance weights being arranged to work in guides, which are graduated to show the opening in inches and feet. Water is fed into the boilers by a compound double-acting ram pump, made by Messrs. Evans, of Wolverhampton, with an injector as stand-by, and the feed water can be passed directly into the boilers, or, alternately, through a feed heater and a Green's economiser containing 96 tubes. A Bruce Peebles 5-kw. shunt-wound motor placed outside the pump-house drives the shafting for the mechanical stokers and the scrapers for the economiser. The main steam and feed pipes are of lap-welded steel, and the whole of the pipework was entrusted to Messrs. Ashton, Frost, and Co., Limited, Blackburn. The steam and feed pipes are all of lap-welded steel, having special thick flanges welded on and drilled for bolt holes. The exhaust pipes are all of cast iron, flanges faced, and the holes drilled and harboured for nuts. The feed pipes are all of steel, galvanised inside and out. The pipes have a special automatic provision for exhausting the atmosphere in event of anything going wrong with the condenser, and are generally arranged in an up-to-date manner.

Engine House Plant.

The generating plant at present at work consists of two combined sets. The larger set (Fig. 5) is composed of a triple-expansion engine, with one high and two intermediate cylinders placed above three low-pressure cylinders, working on cranks set 120deg. apart. The engine runs at a speed of 350 revolutions per minute, and is designed to give 500 i.h.p. with 160lb. steam pressure. To this engine are coupled two Silvertown dynamos, the two being capable of giving an output of 300 kw. at any pressure between 440 and 500 volts. The dynamos are of the single horseshoe

Digitized by Google

type, with drum bar armatures and shunt-wound magnets. The smaller engine is a two-crank compound engine, pressure from 220 to 250 volts, these machines being of the same type as those of the larger set. The engines,

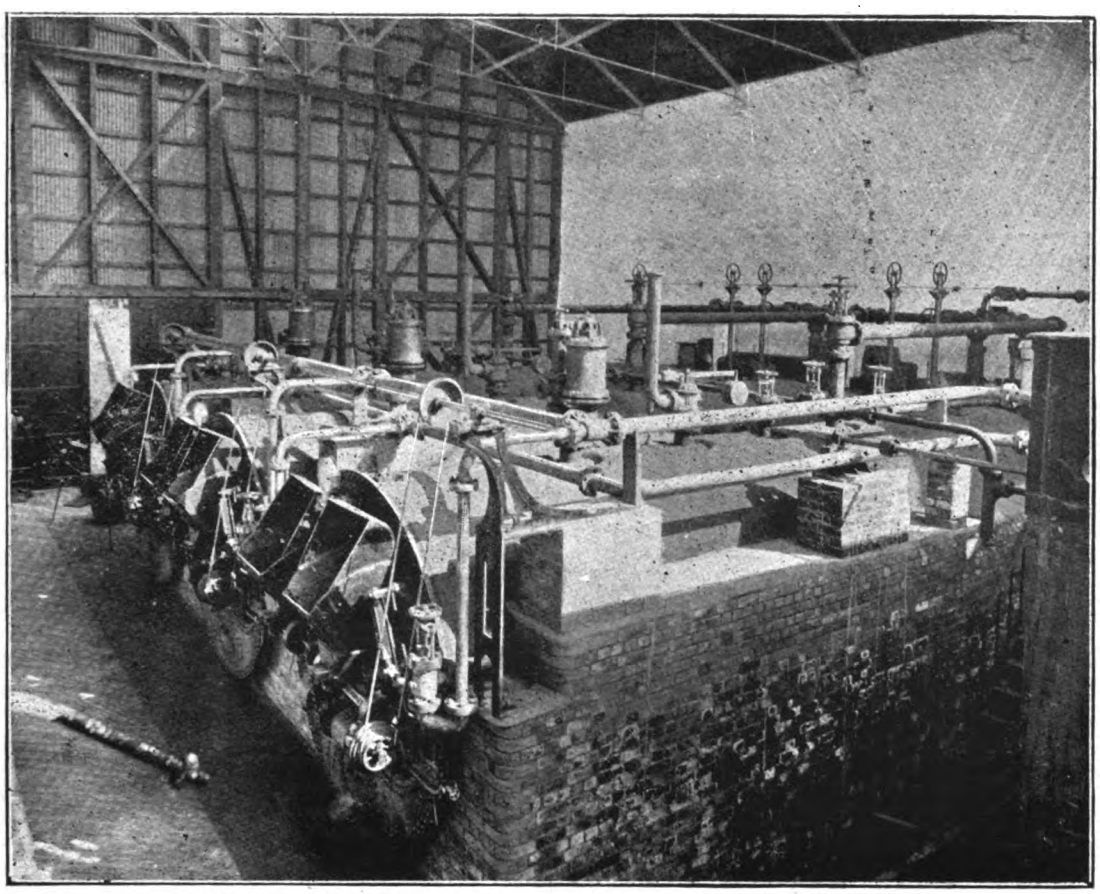

FIG 4.—View of the Gloucester Boilers, showing Mechanical Stokers.

with one high and one low pressure cylinder, working on cranks set 180deg. apart, the steam being distributed by a single piston slide valve of special design placed between them. The engine runs at a speed of 380 revolutions per minute, and will give 250 i.h.p. with 130lb. of steam. The engine drives two Silvertown dynamos, each having a capacity of 75 kw. at any which were made by Messrs. Belliss and Morcom, Limited, of Birmingham, are fitted with their patent system of forced lubrication. In this system a small pump, worked off the main shaft, supplies oil under pressure to a series of pipes, which convey the oil to each bearing, and ensure every working part being thoroughly lubricated. By this means the engines are enabled to

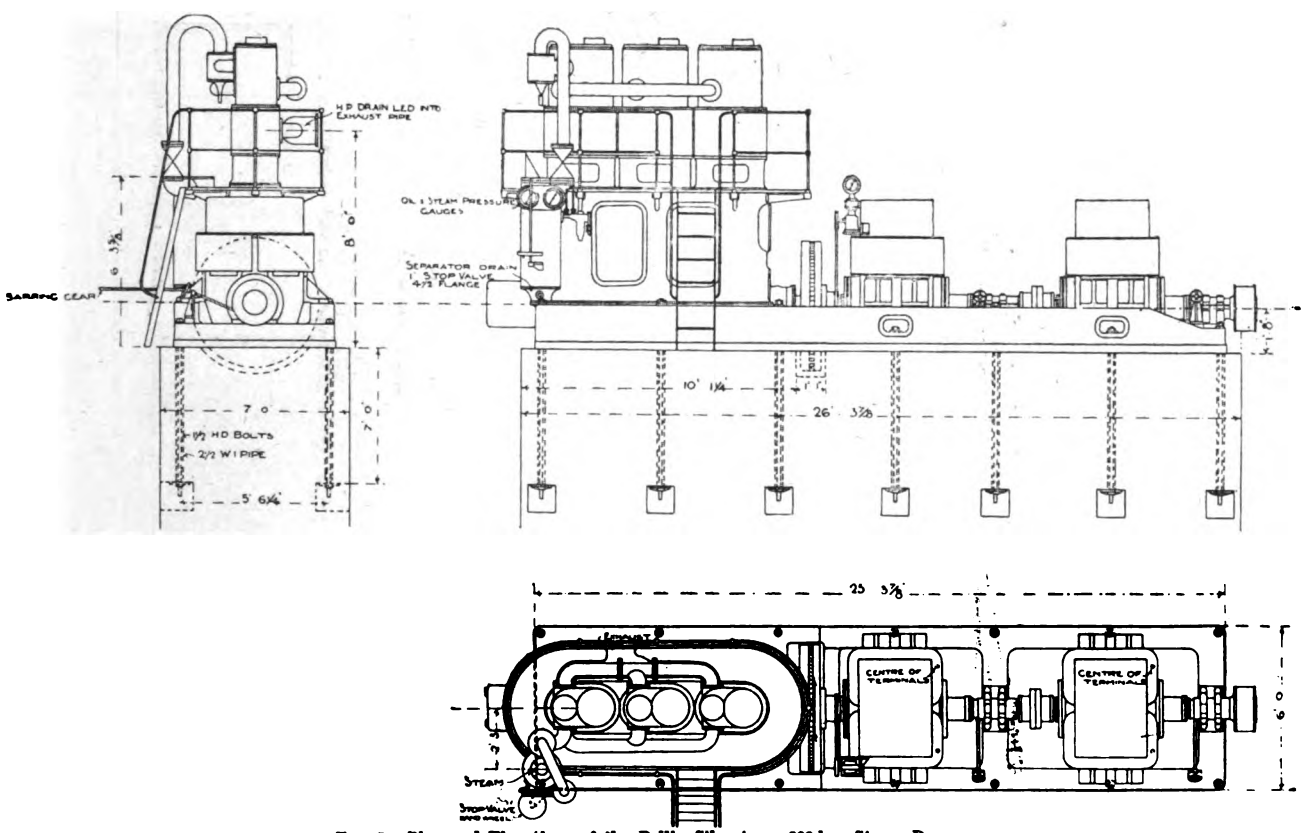

FIG. 5.—Plan and Elevations of the Belliss-Silvertown 300-kw. Steam Dynamos.

Digitized by Google

make uninterrupted runs for long periods without any undue consumption of oil. The design, truth of workmanship, and accuracy of adjustment of the plant are of the highest class, and permit of the engines running

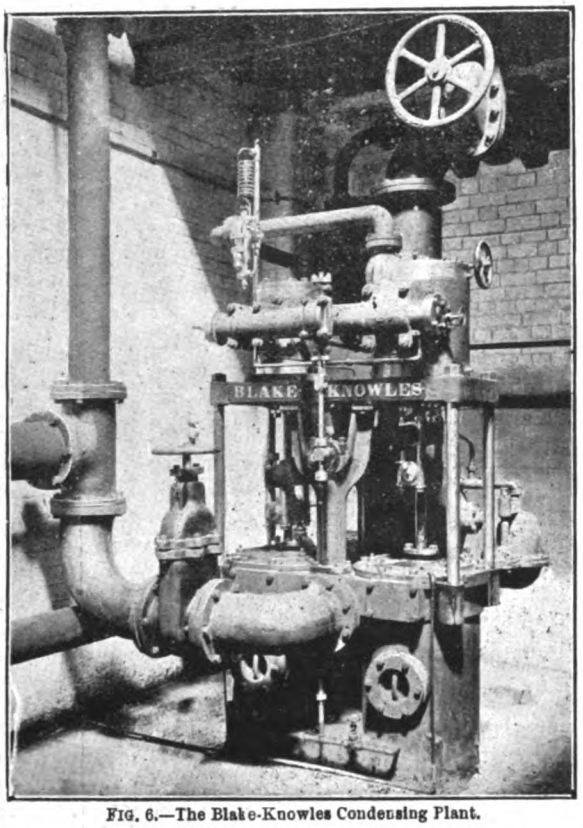

FIG. 6.—The Blake-Knowles Condensing Plant.

quietly and without trouble at the high speed at which they work. A 15-kw. booster is placed in the engine-room, and provides the necessary additional pressure for charging the battery. It consists of two single horseshoe under-type machines, coupled together and mounted on the same bed-plate. One machine runs as a motor, and obtains current from the 'bus bars at 220 to 250 volts. It drives the other machine, which is a generator, and is designed to give a current of 100 amperes at any pressure from 20 to 150 volts when running at a speed of about 780 revolutions. In the condenser pit the Blake and Knowles Steam Pump Company have erected two of their jet condensing plants (Fig. 6) Each of these is capable of dealing easily with 10,000lb. of steam per hour, and of maintaining a vacuum of 26in. under all normal conditions of atmospheric pressure. An overhead travelling crane spans the engine-room. It was made by Messrs. Spencer, of Hollinwood, and will lift a weight of 10 tons. Fig. 7 shows a general view of the engine-room as at present equipped.

THE SWITCHBOARD.

The switchboard, which can be seen in plan in Fig. 3, stands on a gallery on one side of the engine-room. It consists of nine enamelled slate slabs fixed in a wrought-iron frame, which rests on a plinth of glazed bricks. The slates are insulated from the iron frame by ebonite bushes and washers, and the uprights of the framework are hidden by a polished beading, which gives a very neat appearance to the board. The switchboard is divided into three parts: the positive on the right, the booster and battery switches and instruments being in the centre, and the negative on the left. The general view of this switchboard as included in the first contract is given in Fig. 8, but Fig. 9 will be of more interest to our engineering readers as giving the diagram of connections used. These can be readily followed, but we would call special attention to the accumulator switches and to the connections whereby a single boosting dynamo allows of the whole of the accumulators being charged while the accumulators are still on the lighting circuit. In order to do this, the regulating cells are arranged at the earth end of the two batteries. When it is required to charge the accumulators, the discharge switch contact is moved back until the number of cells across either side of the three-wire system is so few that they can be charged at the then voltage of supply. The series of regulating cells cut out of the circuit is then charged by the single dynamo provided for that purpose. The charging contact can be varied in such a way that the end cells when fully charged can be cut out. The path of this charging current from the booster is as follows: From the positive brush to the battery-charging switch of the positive battery, hence through the cells to the discharge contact. From this it passes to the battery-discharge contact on the negative battery, through the end cells of that to the charging

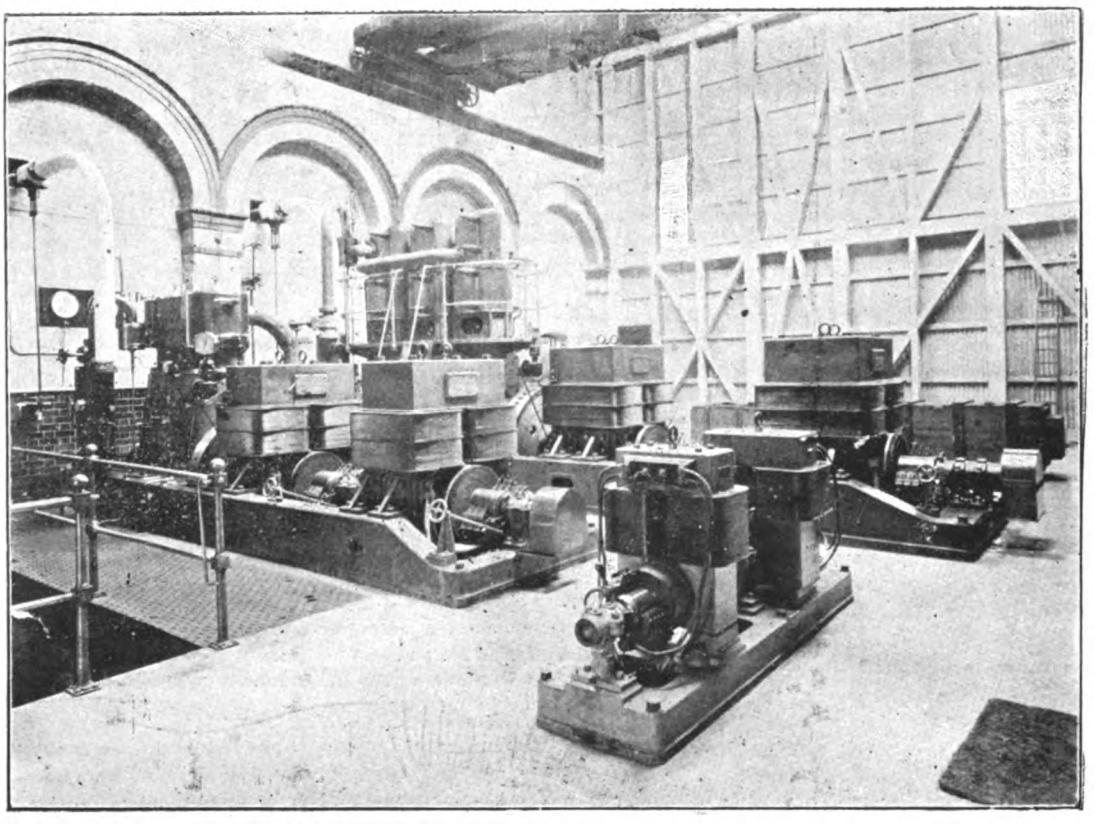

FIG. 7.—View of the Engine-Room at the Gloucester Electricity Works.

Digitized by Google

contact, and back to the booster. These regulating switches would seem, from the front view (Fig. 8), to be of circular form, but these circular series of contacts are only dummies. beneath the handwheel in synchronism with the accumulator regulating switch. In this way troubles from back lash are avoided. In addition to the above, provision is also made that

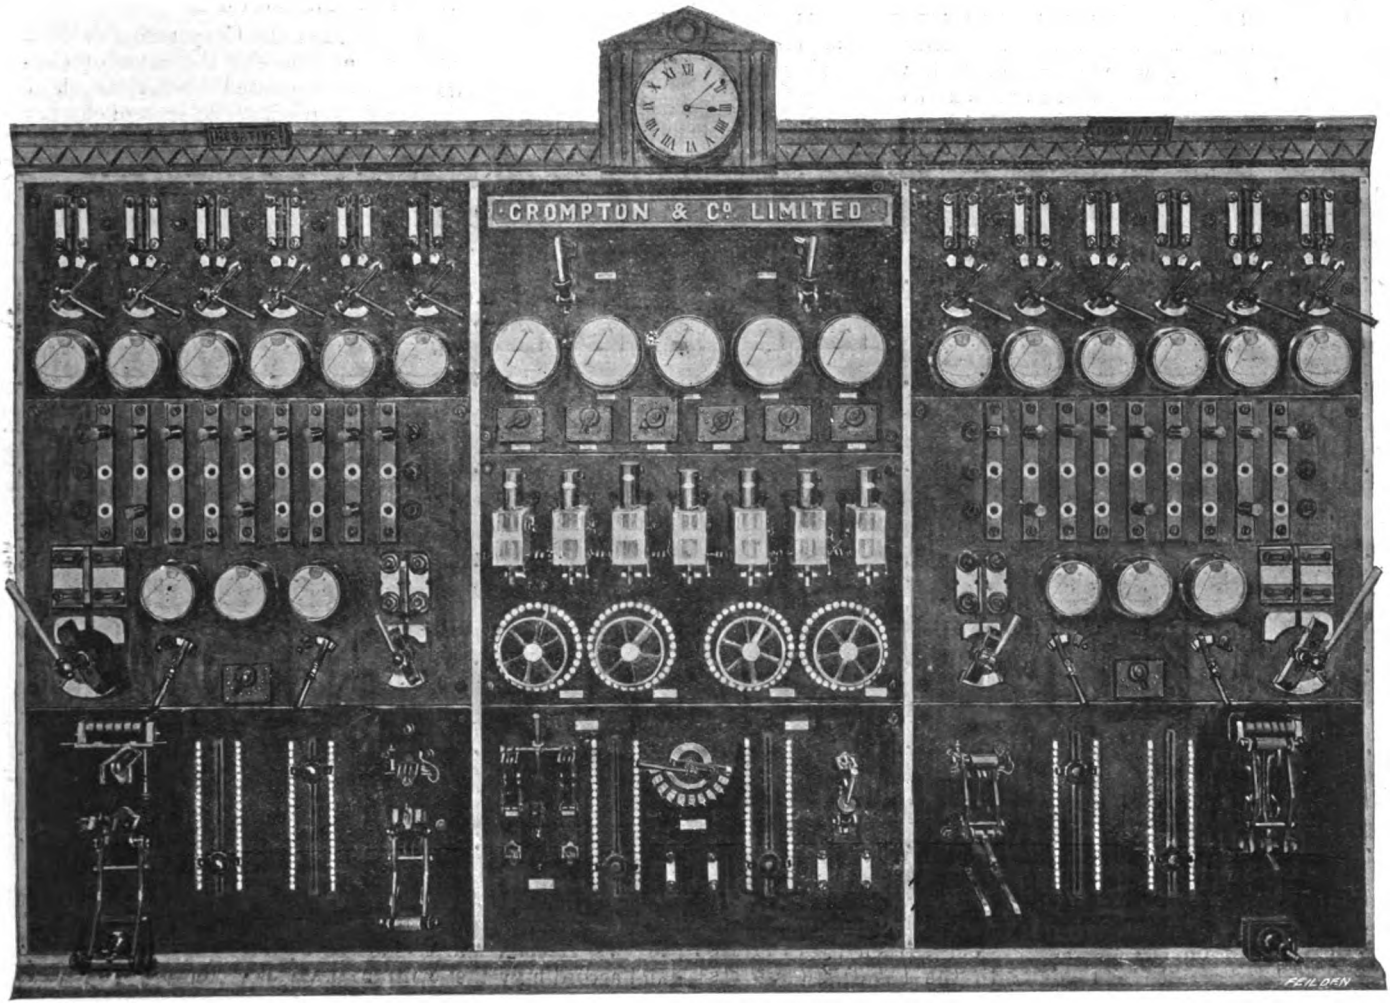

FIG. 8.—Front View of the Gloucester Switchboard.

The switch gear is placed in the accumulator-room, and the handles on the board work by means of bevelled gearing vertical rods, which move the real switch contacts above by the regulating cells cannot be reversed due to the discharge switch being moved ahead of the charging switch. Alarm contacts are provided on the accumulator regulators, which

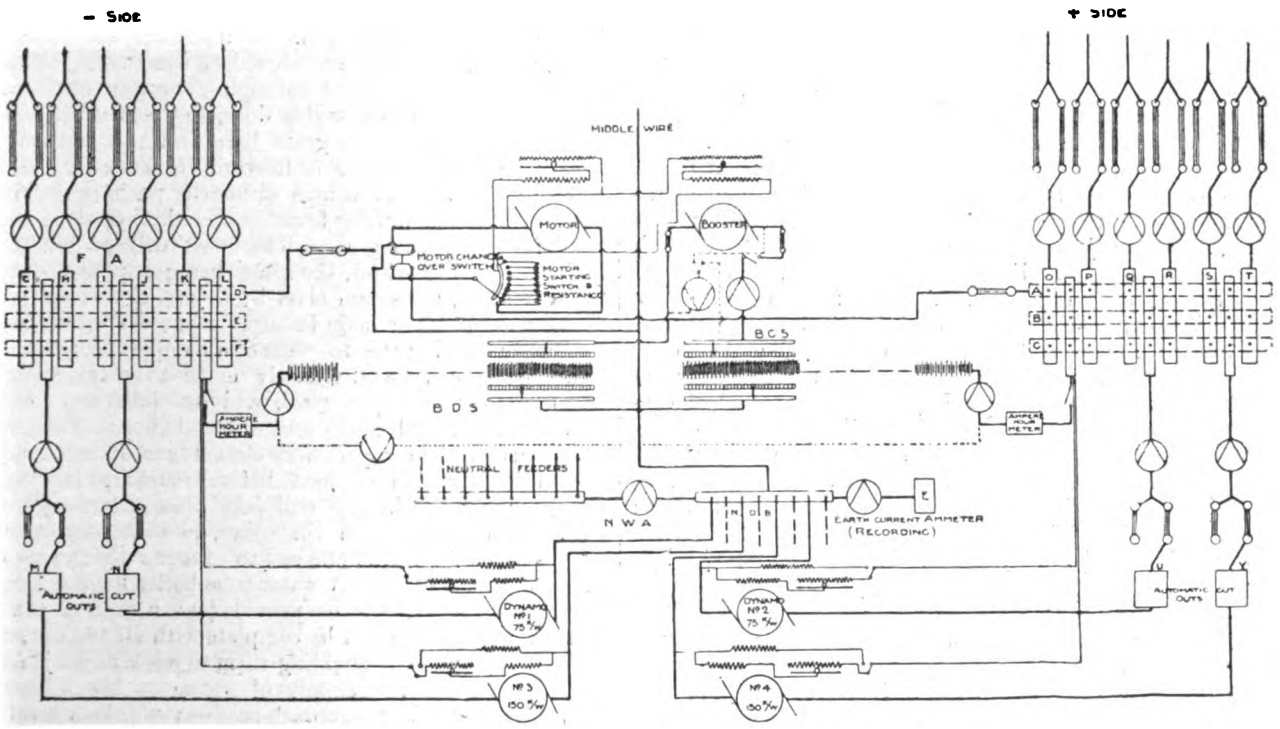

FIG. 9.—Diagram of Switchboard Connections.
B D S, battery discharge switch; B C S, battery charging switch; N W A, neutral wire ammeter.

means of worm gear. In this way a large movement of the handwheel corresponds to one contact, and a suitable reduction gear behind the switchboard keeps the indicator complete the circuit of an alarm bell if an attendant should try to do this. Another good feature in the switchboard is the insertion of slate ledges between each of the duplex

Digitized by Google

fuses, so that the blowing of one fuse may not cause an arc which sets off its neighbour. There are three plug bars on both the positive and negative sides of the switchboard, so that three different voltages can be used if it should be necessary. In connection with the earth a recording ammeter is provided, together with an alarm bell, which rings if the current through the earth circuit exceeds 10 amperes. An automatic switch, which falls at 10 amperes, puts a resistance in between the earth-plate and the centre wire. The whole of this switchboard and gear, together with most of the measuring instruments on it, were manufactured and supplied by Messrs. Crompton and Co., of Chelmsford. The dynamos and the booster are connected to the board by means of indiarubber lead-covered cables drawn into Doulton casing, and the battery is coupled up by ½in. copper rod run on insulators, which are suspended on wrought-iron straps from the roof. The whole of the switchboard work and the cable and copper connections have been carried out by Messrs. Crompton and Co., Chelmsford.

Accumulators.

The accumulators, which were supplied by the Electrical Power Storage Company, Limited, are of their K W S type. Each of the two batteries contains 140 cells, with the following capacities for discharge—*i.e.*, 210 amperes for two hours, or 168 amperes for 3½ hours, or 112 amperes for seven hours, while for a discharge lasting over 10 hours 80 amperes can be taken. There are 30 plates to each cell, which are contained in wood boxes lead-lined. These plates are separated by circular glass tubes held in place at the top and bottom, and the cells are placed on two-tier stands with iron standards and wood bearers. The approximate weight of each cell complete with acid is 435lb., and the external dimensions 2ft. 1½in. by 1ft. 1½in. by 1ft. 7½in. height over all.

The Mains.

This important part of the work was entrusted to the Callender Cable and Construction Company, the mains being laid on the "solid" system. Briefly, this method may be described as follows: In the trench, square cast-iron troughs are laid, into which, at intervals of about a foot, are placed wooden bridge pieces for supporting the cable. A clearance all round the cable is thus provided, so that when bitumen is poured into the trough it flows all round the cable. Over the troughs are laid cast-iron covers. For the private supply the electricity is conveyed from the generating works to various parts of the city by six feeder cables, which feed the network of cable that distributes the current amongst the consumers. The five principal feeders are of ·4 square inch section, the other being ·25 square inch. By the side of each feeder a three-core $^{7}/_{20}$ "pilot" cable, lead sheathed and armoured, is laid direct in the earth, and runs from each feeding point to the main switchboard at the generating works. The distributing mains form a complete network of cables of various sizes, and are joined up to the feeders in Callender's disconnecting boxes. From the distributors, service lines are run to each consumer. All the feeders and distributors are triple-concentric lead-sheathed cables, which are further protected by bitumen compound in the cast-iron troughs. The cable used for conveying the energy to the public street lamps is a $^{7}/_{16}$ single lead-sheathed conductor laid direct in the ground. Each section of the public lighting cable is connected at suitable points to the network. The total amount of cable laid up to the present is 23¾ miles. This length can be dissected as follows: length of feeders, 3¾ miles; pilot cables, 3¾ miles; distributing cables, 12⅓ miles; and arc lighting cables, 3¾ miles.

Public Lighting.

At the present there are 44 arc lamps in use for the street-lighting, these being grouped in four series of nine lamp each and two series of four lamps each, and supplied with energy from the distributing network. The lamps are the Brockie-Pell single-carbon type, and are erected on posts supplied by Messrs. Hardy and Padmore, of Worcester. Each lamp is provided with an automatic switch, which inserts substitutional resistance if the circuit in the lamp be broken. For trimming and repairs the lamps are lowered by means of a winch fitted at the base of the pillars.

System of Charging.

After very careful consideration the Corporation decided to adopt a sliding scale system, whereby the price of electricity to any consumer will be regulated by the length of time during which the supply is used. The scale of charges has been fixed as follows: 7d. per unit for any number of units up to the equivalent of 100 hours' use per quarter of the maximum demand recorded by the indicator and 2d. per unit for all consumption during the quarter beyond the above. The object of this sliding scale of charges is to provide for the payment by each consumer of the due proportion of the charges which are involved in laying down and always keeping ready the necessary plant for the supply of the full unit of electrical energy which the consumer may at any time demand. For motive power the following rates have been adopted: 4½d. per unit for any number of units up to the equivalent of 100 hours' use per quarter of the maximum demand recorded by the demand indicator, and 1½d. per unit for all consumption during the quarter beyond the above. That this is an extremely favourable rate to the consumer will be seen from the following: for a use of one hour per day of the maximum demand, the average price per unit will be 4·5d.; for two hours, 3·15d.; for four hours, 2·32d.; for six hours, 2·05d.; and for 12 hours, 1·77d.

The Refuse Destructor.

The population of the city is about 42,000. The refuse is collected from 9,000 houses three times per week on alternate days, and averages 25 tons per day, or 150 tons per week of six working days. The City Council desired to thoroughly cremate without causing a nuisance, and in such a manner as to utilise the heat in raising steam for the electricity works. Among the various plans submitted in response to the advertisement for tenders, it appeared that the twin-cell destructor of Messrs. Heenan and Froude best fulfilled these conditions, and accordingly the contract was allotted to them. The destructor, having a burning capacity of 50 tons per 24 hours, will consist of two cells side by side, only separated from each other by a low bridge like that at the back of a boiler, so that an open communication exists between the two cells. Each cell will have a charging door on one side of the furnace, corresponding to the clinkering door on the opposite side, and the combustion chamber will be placed above the two cells, extending the whole length of them, the boiler being fixed above the combustion chamber. The feeding will be done through a hopper provided in connection with each charging door, so that the refuse may be put straight on to the grate bars, and the men on the clinkering side can pull it forward if necessary, so that there will be a direct course either by pushing from the charging door, or pulling from the clinkering door, to get the refuse into the grate. The blast will be fed to the underside of the ashpit, the grate being supplied with air blast by a fan, the steam blast by a jet—the whole under entire control. The main feature of the destructor is that by simply altering the direction of a damper the gases from either grate can be alternately made to travel over the hot fire in the other grate, and so into the combustion chamber, and, finally, into the boiler. The whole apparatus will be compact and close together, without any long flues for loss of heat before reaching the boiler. Charging and clinkering will take place alternately, first with one cell and then the other, so that there will be always a hot fire in the one cell to cremate the smoke and fumes from the other. A water-tube boiler having 1,300ft. of heating surface will be provided over each of the two pairs of cells. These will be complete with all the necessary fittings and pipework, enabling them to work in conjunction with the boilers for supply of steam to the electricity works engines. The approach roadway will be a level one on an inclined ground, so reversing the more usual order. A portion of the roadway will be partly of girder construction, so that the space below can be used for coal storage and bunkers. Ample space is allotted for the clinker-cooling yard.

Digitized by Google

Extension of Plant.

As soon as the work of laying the mains was begun, a great demand for electricity was made upon the Corporation by intending consumers, with the result that before the works were completed the demand had already outstripped the effective capacity of the original plant. It was necessary, therefore, to make arrangements for meeting the unexpected large requirements, and extension of the works had to be undertaken before the original plant had been got into use. The extension contracts were allotted as follows: Boiler-house plant—one Lancashire boiler, 30ft. by 8ft. 6in., capable of evaporating 8,000lb. of water per hour, and fitted with Proctor's mechanical stokers. The contract was given to Messrs. Tinkers, Limited, of Hyde, who have now in hand the above-mentioned boiler, which is suitable for a daily working pressure of 160lb. per square inch, the shell of the boiler being made of plates $\frac{7}{8}$in. thick, the flues of plates $\frac{9}{16}$in. thick, and the end plates $\frac{13}{16}$in. thick. The engine-house plant is to be supplied by Messrs. Mather and Platt, of Manchester, and consists of a Willans patent central-valve triple-expansion engine of 500 i.h.p. (3-R size), running at 320 revolutions per minute, coupled direct to two Mather and Platt 150-kw. dynamos. The set is capable of giving an emergency overload of 330 kw. The diameters of the engine cylinders are as follows: high-pressure, 300mm. (11·8in.); low-pressure, 480mm. (18·89in.); low-pressure, 720mm. (28·34in.); stroke, 264mm. (10·24in.).

The supply of current at the station is on the three-wire system at 220 and 440 volts, and the set supplied consists of a couple of the above-mentioned Mather and Platt machines coupled direct to one engine, each dynamo being arranged for work on either side of the system. They are of the four-pole type, and each is designed for a normal output of 680 amperes at 220 to 250 volts, at a speed of 320 revolutions per minute. Each is capable of giving 750 amperes as an emergency load for a period of two hours. The magnet ring is of special well-annealed steel with the limbs cast on; it is divided horizontally at the centre. The magnets are fitted with removable brass spools, and provided with a shunt winding. The armature is of the drum type, wound with copper strip, laid in insulating troughs, and securely embedded in slots on the surface of the core. The armature and commutator are designed with ample through ventilation, enabling the machinery to run for long periods without undue heating. The commutator is provided with a liberal brush surface; there are four brush spindles, each fitted with seven carbon brushes. The bearing is of the spherical adjustment type, and is provided with two loose rings dipping into an oil-well, the arrangement ensuring continuous automatic lubrication.

The extensions to the switchboard were placed in the hands of Messrs. Crompton and Co., the makers of the original board. The condensing plant consists of one jet condenser, capable of dealing with 10,000lb. of steam per hour. This is to be supplied by Messrs. Ed. Chester and Co. The extension plant is in the hands of the manufacturers, and will be ready for use next winter.

The original loan borrowed by the Corporation for the purposes of the electricity supply was £43,450, and at a recent Local Government Board enquiry an additional loan of £18,000 was granted for the extension plant referred to and for the refuse destructor.

Our thanks are due to Mr. Hammond for the use of the drawings from which the diagrams were prepared, and to the various contractors for information given. The views are from photographs taken by Mr. A. H. Pitcher, of Gloucester.

THE HEMINGWAY-COLEY AUTOMATIC REPLACING FUSE.

This fuse, which, we understand, is the invention of Mr. R. J. Coley, is designed to provide against the extinction of light frequently caused by momentary short-circuit. This is done by providing two fuses, the second of which automatically comes into action when the first has been blown. The assumption is that the interval between the blow of the first fuse and the switching-in of the next is sufficient under ordinary circumstances for the accidental short-circuit to have ceased to exist. In Fig. 1 the first fuse is in circuit, which connects one fuse block to the movable contact on the right-hand side of the figure. This contact is constrained by a spring, which tends to close the connection to the subsidiary fuse. It is prevented from doing so by the fuse wire, which is in

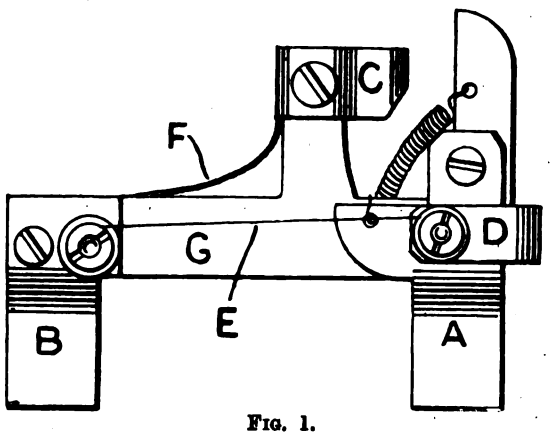

Fig. 1.

tension. As soon as this fuse wire melts, the revolving contact flies over, and put the second fuse in circuit. Fig. 2 shows the apparatus as it would be seen after the first fuse has blown. The letters on the diagram mark the following parts: *a* is the subsidiary contact, and *b* is that contact which is common to both fuses. The plate, *c*, carries the other end of the secondary fuse, and connection is made with this by means of the lever work, *b*. The whole of the fuses are mounted on an insulated bar, *g*, the fuses being labelled *e* and *f* respectively. We are informed that these fuses have stood the test of practical work, but there are certain details in the

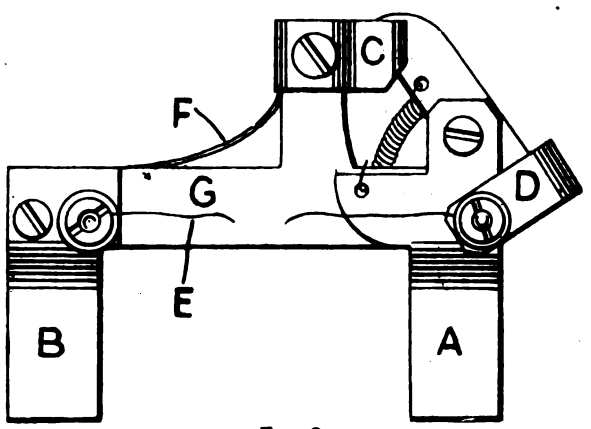

Fig. 2.

samples which have been sent to us which should be modified before they are manufactured in great quantities. We believe they can be procured from Mr. Hemingway, 39, Victoria-street, Westminster.

THE SOUTHPORT ELECTRIC TRAMWAYS.

OFFICIAL INAUGURATION OF THE SYSTEM.

Southport is to be congratulated upon the unmarred success which attended the official inauguration of its system of electric tramways on Wednesday, the 18th inst. One is prepared for hitches on such occasions, but no hitch of any kind whatever occurred during the ceremony in question. Everything worked like a clock, and, indeed, the service of electric trams in Southport might have been in operation for months past for all that a casual observer might have detected, had it not been for the gay manner in which both cars and streets were decorated. According to programme, the guests, who formed a very numerous party, including many well-known tramway engineers and others, assembled at the town hall at 11 a.m., whence they pro-

Digitized by Google

ceeded to Hoghton-street to witness the starting of the first car by the Mayoress (Mrs. T. P. Griffiths), and the second and third by Mrs. G. F. Travis (wife of the chairman of the Tramway Committee), and Mrs. T. Jones (wife of the chairman of the Electricity Committee) respectively. Several other cars also took part in the procession, all being well filled, though not crowded. The cars proceeded in company for a couple of miles or so, and then took different routes to the generating station and new car depôt, which were duly inspected. The journey was accomplished in delightful weather and without incident. During its course those present had an opportunity of admiring the neat, if not elaborate, design of the overhead equipment, while not a few envied Southport its wide, level roads and other natural advantages which help to assure the success of electric traction. The natural advantages in question, coupled with the substantial manner in which the work has been executed throughout, makes the success of the undertaking a foregone conclusion.

The lines opened on Wednesday are entirely new, and at present quite distinct from the other tramways within the borough, though this is not likely to remain the case for long, since further new lines are contemplated, besides the conversion, at an estimated cost of £40,000, of the tramways recently purchased by the Corporation from the Birkdale and Southport Tramways Company. As will be seen in another column, the application by the Corporation for sanction to borrow this amount formed the subject of a Board of Trade enquiry on Tuesday last.

Upon their return from the inspection of the overhead equipment, car depôt, and power-house, which we propose to describe fully in a future article, the guests were entertained to luncheon at the Queen's Hotel. The repast consisted of an excellent cold collation—*mit sud-deutscher Bedienung*—and provided a fitting termination to the day's proceedings. The sole fault was with regard to the speechmaking, which was prolonged to rather an unnecessary length.

The MAYOR (Mr. T. P. Griffiths), who presided, in proposing "The Southport Corporation Tramways," expressed a belief that the new tramways would prove a very successful undertaking. The permanent way was thoroughly good, and the electrical equipment throughout the best that money could buy. He looked to the success of the tramways to find them the money required for the purchase of the waterworks company's concern.

Councillor TRAVIS, chairman of the Tramways Committee, in responding, gave a brief history of the undertaking, remarking that the first real progress made by the Corporation with regard to the tramways of the borough was in 1896, when they bought the lines of the Southport Tramways Company. The lines opened that day were first contemplated in 1897. A provisional order was obtained in August last, and consent was given to their application for borrowing powers at the end of October. The work was begun only in January of this year, from which circumstances it might be deduced that it took about 2½ years to do all the talking about such a scheme and six months to do the work. The lines opened that day represented about six miles of single track, and altogether with the lines contemplated they would have about 18 miles of lines in Southport. They got their current for working the new lines from the same works as supplied the town generally, but it being an alternating-current station they had installed special machinery for the tramways. Altogether they had 3,000 h.p., and had additional building accommodation for 6,000 h.p. more. It was intended to start immediately with the conversion of the Southport and Birkdale line.

Other speeches followed by the representatives of the several contractors, etc., for the work, including Messrs. Macartney, McElroy, and Co., overhead equipment; Messrs. Callender's Cable and Construction Company, Limited, mains; Messrs. Bruce Peebles, generating plant; and Messrs. Dick, Kerr, and Co., Limited, rails and cars. The whole of the electrical work, it should be mentioned, has been executed under the supervision of Mr. C. D Taite, the borough electrical engineer, to whose untiring efforts the success of Wednesday's ceremony was in no small measure due, while the construction of the permanent way, erection of car depôt, and extension to the generating station buildings have been carried out under the direction of the borough surveyor, Mr. R. P. Hirst. Further details of the scheme we hope, as previously mentioned, to give in a future article.

THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

EIGHTH ANNUAL MEETING AT KIEL.

[BY OUR OWN CORRESPONDENT.]

(Continued from page 44.)

Previous to the inspection of the electrical equipment in connection with the Kaiser Wilhelm Canal, described in the second instalment of this article, the members of the Verband were afforded an opportunity of visiting various local shipbuilding yards and engineering works. Several of the warships then lying out in the harbour were also thrown open for inspection, and much enjoyment was found in the trips to these. The ship patronised by the writer was the "Brandenburg," one of Germany's older types of battleship, and resembling in point of dimensions our "Centurion" class. The officers were most courteous in giving information, and afterwards provided tea and coffee on deck, the taste of which was destroyed by the "lager" which followed for those who liked it. Compliments were exchanged and mutual success wished over this after-course, the hosts having little suspicion how soon, perhaps, a final farewell would have to be taken of the charming surroundings, the "Brandenburg" being, by-the-bye, one of the vessels recently selected for the China station, and having already departed to those troubled waters. My best wishes for the successful and safe accomplishment of the duty involved go out with the ship and her gallant crew, as do, no doubt, the wishes of all those who took part in the pleasant inspection of that eventful afternoon.

But this is no place for sentiment. Pages, indeed, might be written about the visits made during the few days of the meeting both from a social and utilitarian point of view, but the space at my disposal suffices only for a cursory notice. In dealing with the several inspections of works, etc., made, I shall therefore confine myself as far as possible to a brief description of their electrical equipment. Before proceeding with such description it might, however, be as well to explain that the same programme of visits served during two days. This arrangement is usual with the Verband, and enables members to see a maximum of the principal attractions, besides avoiding crowding. Without such explanation it might be thought the Germans managed to get through a phenomenal programme in the one day, since I shall continue with the description without reference to dates.

Of the several shipbuilding yards thrown open for inspection, the Germania-Werft (Krupp) Baltische Elektricitäts-Gesellschaft, though not so extensive as the Government's yard, nevertheless afforded great interest, being so thoroughly modern in its equipment, as the name Krupp would alone suggest. The installation serving the yard with electrical energy for lighting and power purposes is situated upon the site of an old wharf, from which central position energy is distributed both to the various workshops and ships under construction. The generators are of the continuous-current shunt-wound type by Messrs. Siemens and Halske. Each of these machines has a capacity of 40 kw., and supplies current at a terminal pressure of from 110 to 150 volts. To assist the primary generators over the load peak, and to supply the requirements of the establishment at night, besides acting as a reserve, a battery of accumulators has been added. This has a capacity of 756 ampere-hours. The two dynamos are driven by means of belts from steam-engines of the compound type. The leads from the dynamos are taken to a switchboard, whence the current generated is distributed into the numerous circuits. A separate main is run to each centre of consumption from the switchboard, at which latter point each main is provided with a double-pole switch. This arrangement has been adopted so as to facilitate as much as possible the location of earths, which are of very frequent occurrence in this class of work.

Digitized by Google

A conductor mast is erected upon each of the ships already launched, to which is connected a flexible feeder from the shore. In the interior of the ship the temporary conductors are carried by porcelain insulators attached to the deck supports. Rivet holes are made use of where it is necessary to pass the conductor through armour plating, the holes being previously lined with vulcanite tubing. The lamps employed are specially protected against mechanical injury. The landing ways and the upper decks of the ships under construction are lighted by means of arc lamps during the winter months. Distributed over the whole yard, and in the numerous workshops, etc., there is at present a total of about 1,200 incandescent lamps, besides upwards of 100 arc lamps installed. In addition to this load, the generators have to supply energy to electric motors aggregating about 50 h.p. For boring large holes in plates, etc., already fixed, portable drilling machines, driven by electric motors are employed. Electrically-driven windlasses and centrifugal pumps are also used. Yet another use for electrical energy is found here—namely, for the propulsion of a boat serving exclusively the requirements of the yard. This is equipped with 40 accumulator cells of 600 ampere-hours capacity for five hours' continuous discharge. The battery is charged at a constant potential of 110 volts.

Considerable additions in the shape of a new wharf, etc., are being made to the yard, which will entail a largely-increased consumption of electrical energy. In anticipation of this, the capacity of the generating plant already installed is to receive considerable additions. In fact, when the contemplated extensions are complete the plant will comprise four 12-pole shunt-wound dynamos, each designed for an output of 800 amperes at 550 volts terminal potential, two shunt-wound machines to yield 342 amperes at 550 volts terminal potential, and two machines of similar type to yield 750 amperes at 250 volts potential. The four large dynamos are to be driven separately by triple-expansion engines of 500 h.p. each, while the smaller dynamos will be grouped in pairs consisting each of a 550 and a 250 volt machine, and driven thus by means of a common 240-h.p. engine to each pair. The feeders to the distributing points are to be laid underground. In the workshops the machine tools will all be driven by means of electric motors, partly in groups and partly on the separate system. The pressure of the supply to the incandescent lamps is to be 240 volts.

(To be continued.)

ALTERNATING-CURRENT INDUCTION MOTORS.*

BY A. C. EBORALL, ASSOCIATE.

In the following paper some practical points connected with the construction, design, and performance of modern single and polyphase induction motors are first considered, and then follows a brief consideration of some recent developments in this branch of electrical engineering. The author originally intended to submit a short paper on starting devices for single-phase motors, but it afterwards occurred to him that it might prove of interest to bring up the whole question of alternating-current induction motors for discussion, as the subject is of considerable interest to many, and has been somewhat neglected in this country up to the present. On the other hand, some apology is needed for presenting such a paper to the Institution, because there is little that is really new in this branch of electro-technics.

Part I.—The Construction of Induction Motors.

(A) *Ironwork.*—The design of the ironwork—that is, of the stator and rotor cores, motor cases, bearings, etc.—is the same for all motors, single or polyphase, because a single-phase motor is practically a polyphase motor running on one phase. While this is perfectly true, and although the general constructional lines are similar in each case, it must be borne in mind that far greater care has to be taken with the design of a single-phase motor than with that of a polyphaser if the best results are to be obtained. The bad effects of magnetic leakage are felt far more with the former than with the latter, and the performance of the motor is affected by apparently insignificant details of design. However, a very good polyphase motor will make a fairly good single-phase motor, as a general rule. The general design of all induction motors with regard to the case and bearings is fairly uniform with all makers. Up to 100 h.p., and for pressures not exceeding 1,000 volts, all standard motors are semi-enclosed, the stator core discs being built up inside a cast-iron case and the bearings carried on open-end shields. Thus the motors are virtually without bed-plates. Bearings are always provided with ring or chain oilers, and the sleeves are of gunmetal for the small sizes and of Babbitt metal for the larger sizes. Shafts are frequently case-hardened in the neck and afterwards ground true.

For larger motors than 100 h.p., and for voltages above 1,000, a more open construction is employed, involving the use of a bed-plate, to which the stator case and the pedestals are bolted. In this case the bearings are usually spherical. With large motors, great care has to be taken to keep the bearings absolutely rigid with regard to the stator case, on account of the relatively small air-gap. For instance, for a 300-h.p. induction motor running at 200 revolutions per minute at 40 cycles, the diameter of the rotor works out to be about 8ft., and the air-gap (iron to iron) would not exceed 0·2in. With such a motor it is absolutely necessary to stiffen the pedestals by means of arms radiating from them and bolted to the stator case.

Stator stampings are usually not less than 20 mils in thickness, and are built up with or without insulation between them. Ventilating ducts are usually provided in the core for all sizes above 30 h.p. Rotors are built up from stouter stampings, which need never be insulated; ventilating ducts in them need not be provided for motors less than 50 h.p., on account of the absence of iron loss in the cores of any appreciable amount.

The windings for both stator and rotor must always be iron-clad—that is, the cores must be provided with holes or slots.

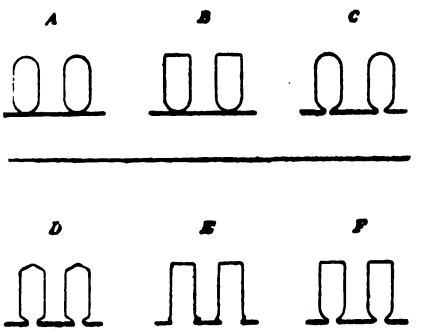

Fig. 1.

In Fig. 1 are illustrated some typical forms of stator holes and slots. The form marked A is the well-known Brown rectangular hole; that marked B is used by Messrs. Kolben and Co.; that marked C is the usual shape used in Germany; those marked D and E are American forms; while, finally, the slot marked F is generally used in the motors built by the author's firm. The greatest winding space is given with square-topped slots; the bottom of a slot or hole is best kept rounded, as it produces a more even pole.

The arguments for and against the use of holes and slots are as follows: With the employment of a hole winding the magnetising current of the motor is reduced to a minimum, because the inner periphery of the stator is smooth all round, and consequently the area of the air-gap is as large as possible. But if the small iron bridges at the bottom of the holes are more than mere shreds of metal, of the thickness of paper, there is considerable magnetic leakage across them, which may greatly affect the performance of the motor. In order to prevent this leakage, not only have the stator core discs to be tooled after being built up—that is, a cut has to be taken off the bore of the stator—but the interior of the holes has to be filed, and so the iron losses are unavoidably increased. A hole winding produces a somewhat smoother pole than a slot winding, but the former is much more difficult to wind, and the conductors are liable to get injured owing to abrasion of the insulation while being pulled through, especially as the holes get nearly filled up with wires, and this injury may easily escape detection at the time.

The only real objection to partly-closed slots is the increase of magnetising current produced by their use (it will generally increase 10 to 15 per cent.), but in the author's opinion this objection is far outweighed by the smaller iron loss and greater convenience attained with slot windings. In many American motors the slots are quite straight, as shown—that is, their sides are parallel; this permits the use of former-wound stator coils, which is an advantage, but on the other hand the magnetising current of such motors is relatively very high. A hole winding is open to another objection: unless a great many experimental data are available it is impossible to calculate the motor in question accurately, as magnetic leakage cannot be estimated with any accuracy. On the other hand, the performance of a motor having open or partly closed slots can be accurately predetermined from the drawings by means of suitable vector diagrams, such as those of Heyland or Rothert.

With regard to the relative proportioning of stator and rotor holes or slots, the lengths of these should not, if possible,

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

exceed 2½ times the width, and the nearer they approximate to square or circular shape, the better. This amounts to saying that the winding depth must be kept down, as otherwise the power factor and the overload capacity of the motor will be affected. The performance of a motor at starting, particularly if it has a permanently short-circuited rotor, and especially if single-phase, may be greatly improved by so designing the rotor that the slots or holes of the latter are not parallel to the holes or slots of the stator—for instance, they may be "staggered" by an amount not exceeding their pitch. This constructional feature, first put forward by Mr. C. E. L. Brown about six years ago, is used with all the induction motors built by the author's firm, including the Heyland single-phase motors, as the results of many tests show it to be of considerable value. The insulation of holes or slots is usually effected by means of insulating tubes of compressed paper, fibre, veneer board, or micanite, the latter material being, of course, best, but not necessary for low-tension motors. The building-up of the stator core in the motor case is an important feature of the design, and, moreover, the details connected with it are frequently neglected. First, the stator core discs should always be supported away from the case; and, secondly, after having been assembled together, the stampings should not be tooled. It is frequently difficult to avoid this after-tooling, more especially on account of the absolute necessity of having everything concentric, and therefore the author thinks it may be of interest to describe one method employed by his firm, as it has been found to give excellent results from all points of view; the method described is somewhat modified for large motors.

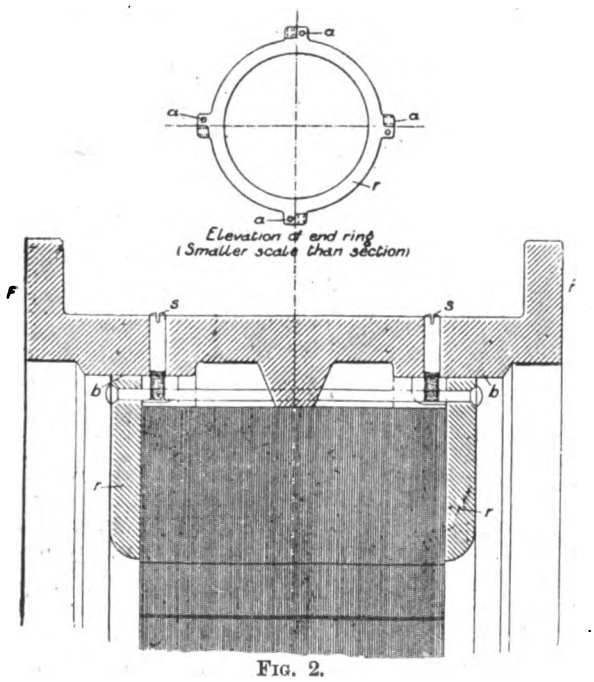

FIG. 2.

The stator core discs are first stamped out of the sheet metal as exactly as possible (with modern American tools great accuracy can be attained), and then built up on an iron mandrel. After this the end rings, *r r* (Fig. 2) are riveted on, the whole arrangement put in the lathe, and the four projections on the rings, *a a*, turned down to the right diameter, but left a trifle full. The case of the motor, already turned on the faces, *b b*, is now heated, and pushed over the core in this condition, so that after cooling the shrinkage of the case hold the core tightly and securely. But to make everything absolutely certain, two or three screws, *s*, fix the case and the core positively. After the core is fixed in the case, the flanges on the latter, F F, are turned down, and must be, therefore, absolutely concentric and true with the stator bore, and true with the axis of the latter. Finally, the slots and end rings are heavily insulated, and the winding put in. The rotor cores are built up in the ordinary manner on the shaft, or on a spider, and are then put in the lathe, and the finest possible cut taken off them. In some cases even this cut is omitted, any slight irregularity or burr being removed by grinding.

The method of building the core into the case described and illustrated above will readily be seen to possess several advantages. These are, firstly, that owing to the core being supported away from the case, leakage through the latter is minimised, and consequently wasteful eddy currents and other detrimental effects are avoided, and, moreover, a free circulation of air can take place all round the core; secondly, the eddy-current losses in the core and teeth are reduced to a minimum, and approximate very closely to the value obtained by calculation; and thirdly, as the core discs are built up quite independently of the motor case, the width of core can be adjusted within certain limits to suit the output of the motor—a great advantage in practice, as it allows a given case to be used for motors of several sizes, and to a certain extent permits convenient variations to be made from standard designs. It is usual with some constructors, notably with Mr. Kolben, to make the end rings or cheeks of the stator cores of brass or gun-metal. It is claimed that by doing this the leakage from pole to pole along the side flanks of the stator is sensibly diminished, or prevented altogether.

(B) *Windings.*—The stator and rotor windings of all modern induction motors are always of the drum type, these windings consisting in all cases either of simple rectangular coils, or regular bar windings, or modifications of the latter—for instance, the so-called squirrel-cage windings. A ring winding has three great disadvantages: firstly, it has an inherently large leakage coefficient; and, secondly, its use necessitates the employment of a massive brass frame around the stator core (in order to minimise magnetic leakage), and it practically precludes the use of an external iron containing-case for the stator, thus making the mechanical construction of the motor difficult and expensive; and, thirdly, there is much idle wire. As already stated, the stator coils of all motors are wound either in holes or slots, and for all usual sizes of motor these coils can be wire-wound with rectangular coils. With single and two-phase motors employing wire or cable-wound rectangular coils there will be two ranges of coils—one range consisting of simple rectangular coils with straight ends, the other range consisting of precisely similar coils, but with bent ends. Thus

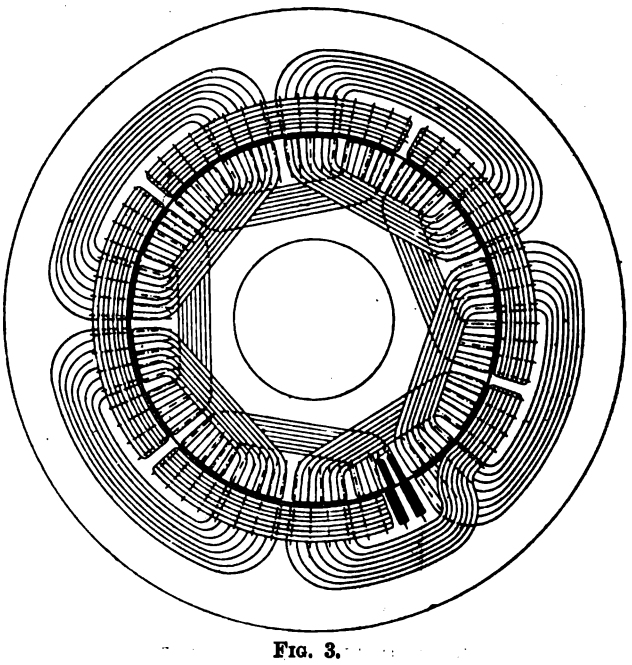

FIG. 3.

each phase of the motor (with single-phasers the starting coils, occupying not more than one-third of the total winding space, may be regarded as the second phase of the motor) will be made up of coils of definite shape, the coils of one phase being bent at the ends up and over the coils of the other phase in order to clear them; from this arises the workshop terms of the "straight phase" and the "bent phase" as applied to two-phase and single-phase motors. With the latter type of motor, the starting phase is invariably the bent phase, from motives of convenience in winding. With two-phase and single-phase motors, it is usual to wind all the poles—that is, considering one-phase only, the coils of this will be wound alternately right and left-handed with regard to the direction of the current in them—that is, they will be cross-connected in the usual manner.

It is clear that for three-phase stators having rectangular coils, it would be a great practical advantage if they could also be arranged for two sets of coils, as with three sets the crossings of the phases at the ends are not only a source of danger (from the insulation point of view), but prevent damaged coils from being easily repaired. Moreover, if each set is in a different plane, there is no possibility of removing the rotor without removing the "bent down" coils, unless the stator core is built up in sections—a quite inadmissible construction. Consequently, for all three-phase stators for motors of standard sizes, and for all high-tension motors, the coils of the various phases are always arranged in two sets, just as for two-phase motors, the coils of a given phase being alternately bent and straight; but in order to do this, and at the same time preserve the proper phase-relation and pitch of the coils, an important modification of the winding has to be made—namely, only poles of the same sign

Digitized by Google

are wound in each phase. For instance, considering one phase only, there will be as many coils as there are pairs of poles, and all coils will be precisely similar with regard to the direction of winding and to the manner of connecting them up. This winding, which simply leaves each alternate pole unwound and doubles the number of turns on the wound poles, is obviously equivalent to the winding referred to above, both electrically and mechanically, but somewhat more copper is required with it, on account of the mean length of turn being greater.

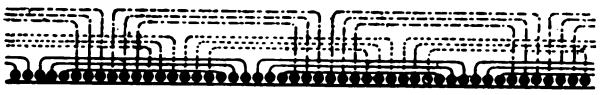

FIG. 4.

It is worthy of note that with such three-phase windings for stators having an odd number of pairs of poles, the winding becomes slightly unsymmetrical at one point, where the end connections of the phases cross one another. This can be readily seen from an inspection of Fig. 3, which shows a six-pole stator. Although for high-tension motors, and for very large low-tension motors, this may be an inconvenience, it is not found to present disadvantages in practice for motors of standard sizes and voltages. As a general rule, too, the speeds of high-tension motors can be so chosen that the number of pairs of poles required is even, while for the large low-tension motors, having an uneven number of pole pairs with bar windings, it is perfectly safe and allowable to wind the stator with three ranges of coils, the end connectors being bent up and back as shown in Fig. 4. Or, should this mode of construction be deemed inadvisable, on account of space for the end connections being limited, or for other reasons, the stator for such large motors can be conveniently and effectively wound with a closed bar winding. Such a bar winding, drawn out schematically for a two-phase motor, is shown in Fig. 5, the four-pole case being taken for simplicity. Standard three-phase stators wound with rectangular coils invariably have the coils connected star fashion. Stator bar windings for large low-tension motors can be, and very frequently are, used with the mesh connection. Combinations of star and mesh are rarely or never found with modern three-phase motors.

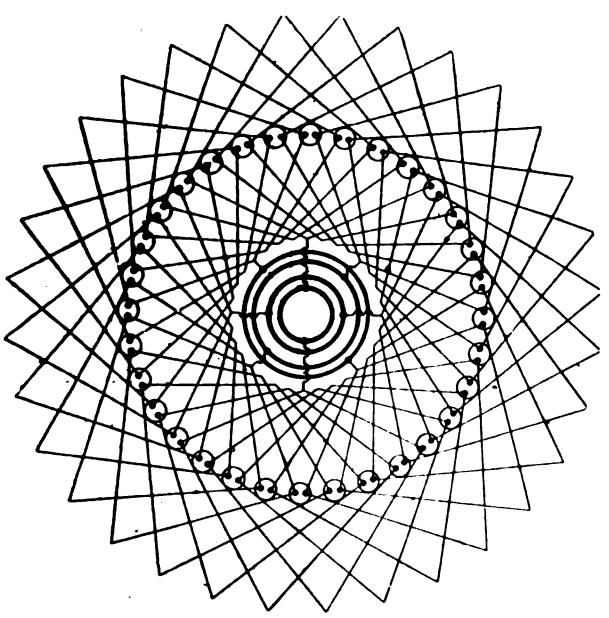

FIG. 5.

The number of holes or slots per stator pole per phase has an important bearing upon the design of all induction motors. In order to keep the winding depth down and to produce an even pole, this number is best made as high as possible—in practice it varies between four and eight. As is well known, with small motors, having squirrel-cage rotor windings, the number of stator holes or slots should be preferably prime to the number of rotor holes or slots, the latter being, if possible, more numerous than the former, as this tends to prevent a cogging-acting action taking place between the stator and rotor fields. The point is, however, of small importance when wound rotors are used.

Rotor windings for all induction motors are of two kinds—namely, permanently short-circuited rotors, and rotors having the ends of the windings brought to slip-rings for the purpose of inserting a resistance into the winding at starting. The design and arrangement of these rotors is independent of the number of phases and of the stator voltage, a given rotor serving for a single, two, or three phase motor, provided that, if slip-rings are used, the number of stator poles is the same in each case, and that the flux per pole in the gap has the same value. There appears to be some difference of opinion as to how far the permanently short-circuited rotor can be used with satisfactory results—that is, at what output of motor it is best to bring in the starting resistance. For motors having to start against load (apart from crane, elevator, and mining motors), the author is decidedly of opinion that the squirrel-cage construction, or its modifications, should be left behind with all polyphase motors above 5 b.h.p. With single-phase motors, which are usually arranged to start up light, wound rotors with slip-rings should be used after 7½ b.h.p. With the Heyland single-phase motors, referred to at length later on, a starting resistance in the rotor is used for all sizes.

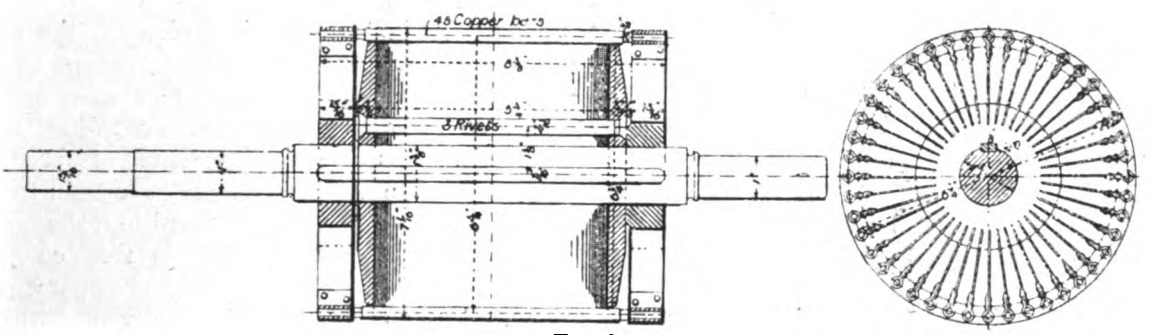

FIG. 6.

If the use of the permanently short-circuited rotor is pushed too far, the pressure regulation of the system, whatever the number of phases, is greatly impaired, owing to the excessive current consumption during the starting-up of the motors. When it is considered that the best polyphase motors with squirrel-cage rotors, and starting under full load, require a momentary rush of current equal to at least 2½ times the full-load current, this statement will be readily believed. It must not be forgotten in this connection that, under such circumstances, the power factor at the moment of starting will be low, with the result that the drop on the transformers, and perhaps even on the generators, is still further increased.

With regard to squirrel-cage rotors, and to the modification of them, the rotor wire-wound with closed coils, there is not much to say. The chief difficulty with the former lies in the fact that it is difficult to make a good mechanical job of the connections to the end rings. If the rotor bars are screwed to these rings, the contact between bar and ring is not only uncertain, but however good it may be at first, it is certain to deteriorate under the influence of the heavy rotor currents, and the heating and cooling of the rotor. Consequently, most makers sweat the rings over the projecting and flattened ends of the bars. But with this, the rings will sometimes melt right off under overloads, splashing the solder all over the stator coils, and generally doing other damage. The author's firm braze the rings on, when a motor of this character is put to work of an exceptionally heavy nature, where overloads are the rule and not the exception, or when the starting conditions are severe. Messrs. Kolben get over the difficulty in the manner shown in Fig. 6; here the rotor bars are connected to the short-circuiting rings by means of thin copper strips used as radial connectors. The rings themselves are of bronze, and are of small diameter, but very massive; they are keyed directly on the shaft without any insulation whatever. In a communication to the author, Mr. E. Kolben states that he has found this construction to prevent entirely the evil mentioned above, and that it greatly assists his single-phase motors to start well, doubtless on account of the extra resistance in the strips. Mr. Kolben also uses this construction for larger motors for crane and similar work (where large starting torques are required without, if possible, the employment of a starting resistance), as it allows of the insertion of the resistance strips of brass or other material in place of the copper connectors.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

WIRELESS TELEGRAPHY.

It is very funny that individuals have a great difficulty in seeing that there are always two sides, or even it may be twenty sides, to every question. Similarly, inventors and patentees have so vivid an idea of their own work that other work in the same direction is ignored. Still, we think that Major Flood Page and the Marconi Syndicate have reasonable ground for grumbling when we consider the position that wireless telegraphy occupies in the public mind. Quite recently the friends of progress were a little startled to find that a successful experimental apparatus was to be taken away, especially when they also heard that the German Government was rather favourable to the introduction of similar apparatus. We must never lose sight, however, of the fact that, while we owe a good deal to Mr. Marconi for educating the public on the question, other scientific men have been experimenting more or less successfully in the same direction. Thus it may turn out that, although one particular set of apparatus has been removed, such removal indicates no intention on the part of the Government to abandon the attempt to utilise some kind of apparatus to give us what we term wireless telegraphy. Indeed, according to the reports from the correspondents at the naval manœuvres, a number of vessels have been fitted up with such apparatus. The position, then, at the present moment with regard to this country is that two or three variants in apparatus are under consideration. Whether any one will ultimately be found to be of service is a question we cannot decide. The *Times* correspondent points out, as long ago we pointed out, that the apparatus as at present used is not efficiently selective—that is, any one receiving apparatus is responsive, not only to one, but to any number of sending apparatus within a given area. Of course, there is a simple, but at the same time it is a somewhat cumbersome, method of signalling so that such interference shall not prove absolutely detrimental to the use of the apparatus. Each sender could, for example, have an individual signal to indicate the beginning and end of his particular word, and no matter how that word came through in the receiving instrument, the person or the position from whence sent would be indicated. It is not, however, our present intention to discuss the failings of any system—in the first place, because no matter what be the step in progress, initial difficulties always arise in the introduction of new apparatus. There are difficulties in relation to wireless telegraphy, but under certain conditions and in certain situations there is no doubt such a system is of incalculable benefit. Why, then, should there be any jealousy from Government departments, or from individuals, to prevent its introduction. Either the experts of our Government department which holds the monopoly of telegraphy are sufficiently educated to know that change, gradual or rapid, must inevitably come, or they know nothing of their own business. If the change, whatever it may be, is for the benefit of the community at large,

Digitized by Google

or any portion of the community, there ought to be no obstacle to its introduction. On the contrary, it ought to receive every help. Yet the following paragraph in Major Flood Page's letter to the *Times* of July 18 savours of autocratic methods of two thousand years ago. It is a stupendous disgrace that such statements can be made at this time of the world's history. Here is a new departure, a departure welcomed by many as an improvement upon older methods, and yet by some unknown cause its introduction is stopped. Whatever the cause or causes may be, it is evident that the root of the obstruction is in a governmental department. Private enterprise is quite ready to take the commercial risks in order to introduce what may be termed a commercial aid, yet the hidden power prevents private enterprise in applying apparatus that might be useful. It is better for us to quote in their entirety the words of Major Flood Page, which are as follows: "Some months ago we arranged with the South-Eastern and Chatham Railways to instal our apparatus on their boats running between Dover and Calais. They are anxious to carry out the arrangement, as safety and security for passengers, and economy in the cost of telegraphing, amongst other advantages, would have accrued, but their steamers are not fitted. Some power prevents it. One rumour says that it is the French Government that prevents it; another that the English Post Office regard this purely commercial application to the needs of a purely commercial company like the South-Eastern as an infringement of the Post Office monopoly. The installation would only be used for the business purposes of the railway company; the public would not be able to use it. Anyway, an obstruction exists. This hidden power, whatever it is, prevents the railway company availing itself of the advantages of wireless telegraphy, and hinders our earning the revenue which would accrue from this mutually advantageous and ordinary commercial transaction." In reply to this accusation the Government department may say, We hold the monopoly. We ask how long a patient public will permit a Government department to stand in the way of progress? Most of us can remember the introduction of telephony. We can remember the position of the Department in connection with that new departure, and no one with the slightest knowledge of the history of the movement can acquit our Postal Telegraph Department from the stigma of being the cause why this nation has about the worst telephonic system of all the civilised world.

Phylloxera Electrocuted.—As up to now no means has been discovered to kill the phylloxera of the vine without killing the plant itself, M. A. Berthier proposes to use electricity. How, he does not yet know; but he advocates people possessing a laboratory and vineyards to make experiments, and some good results ought certainly to be the outcome of this. Could the destructive parasite survive the prolonged action of the X-rays, is one of the questions M. Berthier proposes should be solved. We are sorry not to see more statement of facts as to past attempts by the above.

CORRESPONDENCE

"One man's word is no man's word,
Justice needs that both be heard."

SWANSEA TRAMWAYS.

SIR,—I notice in your very complete account of the Swansea tramways a small error on a point that may be important. The "negative booster" has the series winding of the generator side in series with the armature and the track feeder, not with the positive feeder. This is the arrangement adopted in stations designed by the British Electric Traction Company, as it makes the booster self-regulating within wide limits.

That is not the case with positive feeder excitation, because in practice one does not find a positive feeder in which the current will correspond with that of which the rails must be relieved from moment to moment in order to keep the drop within Board of Trade limits.—Yours, etc.,

THE BRITISH ELECTRIC TRACTION COMPANY, LIMITED,
(Henry M. Sayers, Power Engineer).

London, W.C., July 13, 1900.

THE PREVENTION OF SCALE AND CORROSION IN BOILERS.

BY R. D. SUMMERFIELD.

Although this question is one on which very much has been and is being written by many of the foremost engineers in the country, the author feels that no apology is needed for reiteration on this subject, both on account of its importance and of the fact that even now the majority of steam users appear to be either ignorant or careless of the proper treatment of feed water in order to prevent scale and corrosion in their boilers.

Before putting down any boiler the nature of the proposed feed water should be taken into consideration, and several samples of it ought to be sent to a competent chemist for analysis, so that before the boiler is put to work arrangements can be made for purifying the water in accordance with the results of the analysis.

The indiscriminate use of the nostrums advertised for purifying feed water will in most cases lead to disappointment, as although they may each be of use for some particular kind of water, yet in any other water they would probably do more harm than good, removing the scale, perhaps only to corrode and pit the plates.

There are, however, several makers of patent boiler fluids who analyse the feed water first and then supply a preparation to suit it, but as the use of soda in the proper manner and proportion will bring about the same result much more cheaply, the use of any patent fluid is quite unnecessary.

Apart from these patent preparations, the number of different substances which have been put into boilers with the object of preventing or getting rid of scale is almost incredible. Paraffin, soft soap, tallow, oak bark, elm bark, nutgalls, sugar, molasses, starch, soda, potash, lime, linseed, carcases of animals, potatoes, spoilt flitches of bacon, logwood chips, sawdust, muriate of ammonia, or sal ammoniac, washing over with Portland cement, or with blacklead and paraffin, Irish moss, chloride of tin, etc., are some of them, and many of these are used regularly at the present day.

The impurities of feed water are of two kinds—those held in suspension and those held in solution. The former consist of particles of clay, earthy matter, sewage, refuse from towns, etc., disturbed by the water in its passage, and may be got rid of by allowing the water to remain quiet for some time, when the impurities held in suspension will fall to the bottom as fine mud.

The impurities held in solution in most waters drawn from rivers, canals, lakes, or wells consist principally of sulphate of lime, bicarbonate of lime, and carbonate of magnesia, and analysis may also show traces of silica, salts of iron, sulphate of potash, chloride of magnesia, nitrate of calcium, and various acids, but the three first named, especially the sulphates and bicarbonates of lime, are

Digitized by Google

nearly always present in quantities out of all proportion to the remaining impurities.

Carbonate of lime, the principal constituent of selenite, chalk, marble, and limestone, is held in solution in fresh water by an excess of carbonic acid, and is really present in the form of a bicarbonate. In order to precipitate this, the excess of carbonic acid must be got rid of, and this can be done either by heating the water or by employing a reagent. The solubility of the bicarbonate diminishes with an increase in temperature, becoming nil at a temperature of about 290deg. F., corresponding to a gauge pressure of about 45lb. per square inch. At the ordinary pressures of 80lb. to 150lb. it is rapidly precipitated in boilers or feed heaters.

The precipitation may also be caused by introducing caustic lime or caustic soda into the water, as these substances take up the excess of carbonic acid and set free the carbonate of lime, which falls to the bottom as a white powder and settles in the quietest parts of the boiler, where the circulation is worst, remaining for some time as soft sludge or mud, but if not blown or washed out it cakes into a hard mass, which has to be chipped off.

In the lime process, such as Clark's or Archbutt and Deely's, about half a grain of caustic lime is added per gallon for each grain of bicarbonate, which causes a precipitation of nearly twice the weight of the caustic lime introduced, but this process requires for its successful application large settling tanks, containing not less than six or seven hours' water supply, besides other plant, so that the first cost is high and a good deal of space is required. These objections are often sufficient to prohibit the adoption of this system of purification.

In the caustic soda process the precipitation may be carried out in the boiler, only one small tank being required in which to mix the soda with the feed water. The proportion per 1,000 gallons is 1½oz. of pure caustic soda for each grain of lime per gallon; for instance, a water containing 10 grains of bicarbonate per gallon would require $10 \times 1\frac{1}{2} = 15$oz. of caustic soda for each 1,000 gallons. Carbonate of lime is soluble in 62,500 parts of pure water at freezing point.

Sulphate of lime, which is the same as gypsum or plaster of Paris, is also insoluble in water at a temperature of about 300deg. F., its greatest solubility being at 95deg. F., when it dissolves in 393 times its weight of water. At freezing point it is soluble in 500 parts of pure water, and at boiling point in 460 parts. If allowed to settle on the plates the sulphate soon forms a hard scale, sometimes as hard as stone, which causes great danger of overheating and great loss of fuel, about 10 per cent. more fuel being required with scale $\frac{1}{16}$in. thick, and double the quantity of fuel when the scale is ¼in. thick.

The sulphate may be precipitated in the same way as the carbonate by heating the water to a temperature of about 300deg. F., corresponding to a gauge pressure of 50lb. per square inch, or it may be precipitated by the addition of pure carbonate of soda, in the proportion of 1¾oz. of soda per 1,000 gallons of water used for every grain of sulphate of lime per gallon found in the water. Thus, if a water were found on analysis to contain five grains of sulphate per gallon, then $5 \times 1\frac{3}{4} = 8\frac{3}{4}$ ounces of carbonate of soda would be required for each 1,000 gallons of water used, but care should be taken that the carbonate of soda, and also the caustic soda used for carbonate of lime water, are as pure as can be obtained, or foreign substances may be introduced into the water, which may bring about chemical changes by no means to be desired.

Carbonate of magnesia, or magnesian limestone, forms scale in the same manner as carbonate of lime. It is soluble in 5,532 parts of pure water at 32deg. F., in 9,623 parts of water at 212deg. F., and insoluble at the same temperature as carbonate or sulphate of lime. It may be precipitated by the use of carbonate of soda in about the same proportion as for carbonate of lime, but the best way to get rid of it is to heat the feed water before entering the boiler. In brackish water chloride of magnesia may be present, and when concentrated this decomposes at 212deg. F., forming magnesia and hydrochloric acid, which latter, on being set free, rapidly corrodes the iron.

This brings us to the question of acid waters, which are as dangerous, although not so common, as scale-forming waters. Besides the hydrochloric acid, which is formed as mentioned above, water may contain tannic acid, produced by the decomposition in the water of the bark, leaves, or wood of various trees, such as oak, hemlock, logwood, etc., acetic acid, formed by chemical changes from sugar or other sweet substances, carbonic acid, produced in putrid waters or waters turning putrid, and various other acids, which all, however, show their presence by pitting or corroding the iron plates and other parts of the boiler more or less rapidly. Acid waters should be treated by the addition of an alkali in order to neutralise the acid. The best alkali to use is pure carbonate of soda, which should be added in the proportion of one grain of soda per gallon for each degree of acidity in the water. The soda should be mixed with the feed water in a separate vessel before it enters the boiler, as it often causes foaming when introduced into the boiler itself.

Although the chief danger to a boiler from the presence of oil or grease is overheating and foaming, yet substances of this description are also indirectly the cause of scale and corrosion, and great care should be taken to prevent them entering the boiler. The grease or oil floats on the surface of the water and mixes with the carbonate of lime, which, when it is present, often floats on the surface also as a loose powder before it falls to the bottom. The mixture of oil and lime forms a sticky paste, which adheres to the hot parts of the boiler so closely that blowing out two or three times a day will not move it, and in time it hardens and becomes a dangerous scale. Then the grease may decompose and form acid, as mentioned before.

Feed water drawn from the hot-well of a condensing engine is always more or less greasy, and should be passed through a good oil-filter before entering the boiler, but as grease or oil may enter from other sources—from the boiler fittings, for instance—a scum trough should be fixed in the boiler, and this should be blown out every time the bottom blow-off cock is opened, say three times a day. Blowing out is a most important point in the prevention of scale. It should be done at regular intervals several times a day when the boiler is working, no matter whether the water has been chemically treated before it enter the boiler or not. The great point, however, is to prevent the scale-forming substances from entering the boiler at all, so that it may contain nothing but sweet and pure water, and practically the only way to bring this about is to employ some form of feed-water heater.

The proper way, then, to treat feed water containing sulphate or bicarbonate of lime or carbonate of magnesia is first to dissolve in it pure soda in the proportion mentioned above, and after that to pass it through a vessel in which it is heated to a temperature of about 300deg. F. before entering the boiler.

The design of an efficient feed heater is not a simple matter by any means. Numbers have been tried, and quantities of patents are still taken out in connection with them, but the best are a long way from engineering perfection. The principal points to be considered in a heater are that the water must not pass through it too quickly, in order that the impurities may have time to be precipitated. For this reason also the heating surface must be as large as possible; the heater must be strong enough to stand the full boiler pressure; it must be simple, not liable to get out of order, easily got at, and easily cleaned out, which last is the most important point about it, as its efficiency depends on the cleanliness of the collecting surfaces, and if these are difficult to get at, the cleaning will surely be shirked by the boiler attendant, with the result that the water, not being able to deposit all its impurities in the heater owing to the thick deposit of scale already there, carries the remainder into the boiler.

In the author's opinion the question of cleaning should receive more consideration than any other in the design of a feed heater; he would suggest that the shell of the heater be a plain cylindrical drum having a cover bolted to each end, the drum to be of sufficient diameter for a man to work in, and to be placed across the main flue in such a position that both covers might be easily taken off for cleaning. The feed water, after passing through a tank in which a proper proportion of soda has been dissolved,

Digitized by Google

should enter at the circumference of the drum, and pass first over the surface of the outer shell, afterwards passing over inner surfaces, and finally being taken away to the boilers from the centre of the heater. The internal part, consisting of baffle-plates and water passages or tubes, should be made to slide easily into the drum, so that it might be withdrawn bodily for cleaning, and a duplicate internal part should be provided, which could be slipped into the drum as soon as this had been scraped out. This would greatly lessen the time during which the heater would be out of action, and would ensure the thorough cleaning of the part taken out, as the manager would be always able to see it before it went into the heater again. It is important that the cleaning should take place at regular intervals, depending on the quality of the feed water. With some waters the heater might require cleaning out every three or four days, while with others a monthly or bi-monthly cleaning would suffice; the quality of the feed will also determine the amount of water which must be blown out of the heater every day through the blow-off cock, generally a quantity equal to the contents of the heater should be blown out every six hours.

In the author's opinion a suitable feed-water heater and purifier is as necessary to a boiler as the firegrate, and when steam users generally begin to realise the enormous saving in the coal bill which is effected by a boiler always clean and free from scale, no doubt feed heaters will be considered indispensable.

At present there is no heater on the market which can be said to have stood the test of time satisfactorily, and many persons have even discontinued the use of them after a time, principally owing to the difficulty of keeping them properly clean. This question of cleaning is of the utmost importance, as mentioned before, but it is a point which inventors often miss, and, in fact, one which is frequently missed by buyers as long as the apparatus gives good results when new.

This refers to boilers quite as much as to feed-water heaters. For instance, during the last few years a number of water-tube boilers have been brought out with variously curved tubes, and some of these boilers have given wonderfully good results when tested for efficiency; but unless the water supplied to them has been purified, or is naturally pure, the author imagines that this efficiency will soon fall below that of an ordinary Lancashire boiler unless they are kept very clean, the cost of which will probably more than equal any increased gain in evaporative power—in fact, it is probable that a short experience of these kind of boilers will bring out the fact that without a thoroughly efficient feed-water purifier the enormous cost of cleaning the tubes will prohibit their use altogether.

LARGE TURBO-ALTERNATOR.

We are pleased to hear that the newly-formed Brown-Boveri-Parsons Syndicate have received an order from the Frankfort Corporation for a 4,000-h.p. single-phase turbo-alternator for the extension of their well-known central station. The present plant in that station consists of four 500-kw. units and two 1,000 kw. units, while two more 1,000-kw. units are being erected. It is interesting to note in this connection that, although a single-phase plant, yet the total capacity of the motors connected to the Frankfort mains exceeds 5,000 h.p., which is the best possible proof that a properly-proportioned single-phase installation compares favourably with others, even as regards power distribution. At all events, there is no town in England which can show a motor load approaching that of Frankfort. The fact that the Frankfort Corporation have, acting on the advice of their resident and consulting engineers and on the report made by a committee of eminent engineers, decided to adopt steam-turbines is a proof that these have come to stay, the more so because all the machines installed in the Frankfort central station up to the present were built by the most renowned Continental firms, and are coupled to splendid engines of the latest types.

The turbo-alternator which has been ordered will run at a speed of 1,360 revolutions per minute, giving current at a pressure of 3,000 volts. It will be capable of giving its full output of 4,000 h.p. when working on an inductive load having a power factor of 80 per cent. The alternator will be provided with a special winding, by means of which it can be made to generate three-phase current, in which case its output will be 5,000 h.p. The set will be by far the largest turbo-alternator ever made, and, moreover, will rival in power with the largest reciprocating steam-engines ever built for direct connection to electrical machines.

MUNICIPAL ELECTRICAL ASSOCIATION.

CARDIFF CONVENTION.

(Concluded from page 50.)

The following was the next paper read:

On the Maintenance of Certain Portions of Distributing Systems at Earth Potential.

BY C. H WORDINGHAM, M.I.C.E., CITY ELECTRICAL AND TRAMWAYS ENGINEER, MANCHESTER.

From the very earliest days of the application of the science of electricity to practical needs, the earth, or, as our American brothers prefer to term it, the ground, has played a prominent part, and each branch of electrical industry has in turn set up a claim to a vested interest in it. The potential of the earth is usually taken as zero, other potentials being reckoned with respect to it. This, however, does not accord strictly with the facts, since a difference of potential may, and very frequently does, exist between two points on the earth's surface. Such difference of potential, however, is never very great. The earth, in some text-books, is regarded as forming a large reservoir, and its office is stated to be that of maintaining the potential of a point connected to it at zero. Thus, if a battery has one pole connected to earth and the other to one end of a long conductor, and the far end of the conductor be connected to earth so that a current flows, the earth is regarded as merely absorbing the electricity that passes along the wire by draining down its potential to the same value as the potential of the earth at the battery end of the line, and no actual current is supposed to flow through the earth back to the battery. This explanation is not borne out by experience, as the return currents can actually be detected, and it is more correct and more convenient to regard the earth as a large conductor through which the current actually does flow. The earth may be used in two distinct ways. It may either be employed to take the place of an ordinary conductor, as in telegraphy and telephony, in which case the whole of the outgoing current has to return by the earth, or it may be employed merely to keep one of the conductors of an electrical system at or near zero potential.

No one would now think of intentionally employing the earth in the former manner when energy was to be transmitted at any appreciable rate, and even for signalling circuits its use in this manner is attended with great disadvantages. We may therefore confine our attention to the second way in which the earth is employed—namely, to keep down the potential of one portion of an electric system of transmission. It will be convenient in considering the various practical instances of earth connections to divide the subject into high-pressure and low-pressure circuits, and to further subdivide the latter into those circuits which have a conductor earthed at one point only, and those which are earthed at more than one point. If there be a two-wire circuit, consisting of a generator, two conductors and a consuming device, such as a transformer, and if a given difference of potential be maintained between the two conductors by the generator, then if all parts of the circuit be equally well insulated, each conductor will assume a potential relatively to the earth which is half the difference of potential between the two. In other words, if the pressure be 10,000 volts one conductor will be 5,000 volts above earth, and the other 5,000 volts below earth. If, however, the insulation resistance of one conductor falls below that of the other, the conductor's potential with respect to the earth will at once diminish, while that of the other conductor will increase, and, if the insulation of one conductor fail altogether, it will arrive at earth potential, while the other conductor will alter to 10,000 volts above or below the earth, as the case may be.

Now, it is obvious that if the conductors be insulated only with a view to withstanding the normal potential from earth—*i.e.*, 5,000 volts, an undue stress will be placed upon the better-insulated conductor when the insulation resistance of the other falls, and this stress may be sufficient to cause the other to break down also. Inasmuch as it is impossible to foresee which conductor may assume the potential of the earth, it would appear that if both have to be insulated, both must be

Digitized by Google

capable of withstanding a pressure of 10,000 volts. It was first pointed out, the author believes, by Mr. Ferranti, that, seeing that either conductor might have to withstand the full pressure, it would be best to at once face the situation and insulate one of them for the maximum pressure possible, and ensure that it alone should be subjected to this pressure by deliberately connecting the other conductor to earth. This exceedingly simple, and at the same time ingenious device, at once diminished the risk of breakdown and cheapened the cost of insulation, but at the same time it enabled a further great advantage to be reaped by admitting of much greater security to life being introduced. This end was attained by completely enclosing the insulated conductor within the uninsulated one, thus rendering it physically impossible to handle a conductor at a dangerously high potential; and if by any chance the outer conductor should be cut through, a short-circuit would be established before the inner conductor could be touched. This system has been almost universally adopted for two-wire high-pressure circuits, and is perfectly familiar to all at the present time, but it is worth while recording the fact that when originally introduced many people looked askance at connecting a high-pressure conductor to earth.

For systems of transmissions employing more than two wires the same perfect security cannot be attained, but a near approach may be made with two-phase working by employing two separate concentric cables, the outer conductors of which are connected to earth, or by enclosing two parallel conductors within an outer envelope. In three-phase working, if a star winding be employed, the middle point of such winding may be connected to earth. When this is done, the stress on the insulation from earth is diminished to the smallest possible value, but all three conductors have to be insulated. It is important that one point only of the zero potential conductor should be conducted to earth, because, inasmuch as there must of necessity be some fall of potential in the outer conductor, there exists between any point and the one connected to earth a difference of potential depending upon the resistance of the conductor and the current flowing through it. So long as the outer conductor is insulated from earth, except at one earth connection, no current can pass through the earth, but if a connection be established with earth at some distant point, the difference of potential between it and the other point will cause current to flow through the earth.

A digression may here be made to point out exactly the manner in which such return currents travel through the earth. A most instructive experiment carried out by the author in his student days, under Prof. W. Grylls Adams, made such an impression on him, and has been found by him to be so helpful, that he may perhaps be pardoned for describing it. In a large flat sheet of tinfoil two needles were fixed, connected respectively to the two poles of a battery, which thus sends a current through the tinfoil. A sensitive galvanometer was provided and its ends connected each to a needle; one of these needles was stuck at random into the tinfoil, and the other was moved about on the tinfoil until a point was found which gave no deflection on the galvanometer. The needle was then pressed into the tinfoil, and an impression left on a sheet of clean paper underneath. A series of such positions were found, corresponding to an equipotential line in the tinfoil. The first needle was then moved to a new position and a second equipotential line traced out. When a sufficient number of such lines had been determined, other lines normal to them were drawn between the two points to which the battery had been connected. This, of course, represented the lines of flow of the current. Anyone who carries out this experiment for himself will be at once struck with the number and diversity of the paths along which the current can flow. These paths spread out in the same manner as the lines of force from a magnet, and extend to a great distance away from a direct line. In the case considered of a conductor carrying a heavy current and earthed at two points of its length, the current may return from one point to the other by paths that are an almost incredible distance away from the main conductor, though, of course, the bulk of the current will take the shortest possible path through the earth. If two plates be buried in the earth at two points along a line of flow, and be connected together through a conductor, this conductor will take up a portion of the current. If the conductor be part of a signalling circuit the signalling currents will be interfered with, and with any conductor electrolytic action may take place at one or both points of connection with the earth. If, instead of dealing with the high pressures, we are dealing with low, exactly the same effect will be produced by making one or more earth connections to a conductor, but the objects of making the earth connection are usually different.

In the case of a low-pressure distribution system, the object of earthing one conductor is not to diminish the cost of the insulation, since no appreciable saving is made by using a pressure of, say, 200 volts instead of 400 volts, nor is it to secure safety to life; the chief object is to enable a consumer to be supplied at such a pressure that no one of the conductors brought into his house will exceed the limit of pressure defined by the Board of Trade to be low pressure. In the case of electrically-driven tramways, the one object is to enable the rails to be used as one conductor, chiefly with a view to simplifying the working arrangements, and partly to enable the conducting power of the rails, which must in any case be laid, to be utilised. In this last case it is obvious that the conductor is connected to earth throughout its length, and the only way to obviate the difficulties pointed out on the score of current returning by the earth is to keep the difference of potential between the ends of the earth conductor so low as to cause the amount of current returning by the earth and metallic structures buried in it other than the rails to be very small. With these preliminary observations we may now consider some particular cases. The author regards all the high-pressure systems as systems of transmission, though it is true that at present high pressure is still used to some extent for distribution. Inasmuch as this paper deals only with the earthing of distribution systems, the author proposes to confine his attention to these.

The most important case of earthing conductors is undoubtedly that of tramways. The system adopted so largely in America has been imported into this country, and every tramway system, excluding battery-driven cars, is being worked with one conductor insulated and the other, consisting of the rails, connected to earth. It is well known that if the difference of potential between the end of the earthed conductor which is connected to the source of energy differ in potential considerably from that of a distant point on the same conductor, the current returning through the mass of the earth and through pipes buried in it may be very large, and may cause most serious damage to the pipes by causing the metal to be dissolved at the points at which the current leaves. How great this difference of potential must be before serious damage is done is a matter upon which there is not a large amount of information available. The Board of Trade have fixed the limit of what may be allowed at seven volts, but it is maintained by some authorities that this limit is too high, and that a lower potential than seven volts will cause damage. This point is receiving a considerable amount of attention at the present time, and the author is himself engaged in a joint investigation with engineers of other departments of the Manchester Corporation with a view to thoroughly thrashing out what is the minimum difference of potential that can be allowed. It is obviously in the interests of all concerned to arrive at reliable data on the subject. If seven volts be found to be safe, well and good; but if not, the sooner it is known to be dangerous the better.

All engineers must be agreed that the lower one can keep down the difference of potential the better. The object may be effected in various ways. One of the most common is to provide auxiliary conductors of low resistance, which are tapped on to the rails at various points to supplement their conductivity. Another device is to employ similar conductors, but to lower the potential of the far end by means of so-called negative boosters, which subtract instead of add a certain number of volts. A third means, and in the author's opinion the best and most effectual, is to feed the line from a number of independent points either by means of a number of generating stations, or, preferably, by means of a number of transforming sub-stations. Except in the case of very heavy traffic, this method should prove effectual without either the employment of return feeders or negative boosters. The simplicity and reliability of the so-called overhead system of traction are such as to render it worth while to go to great lengths to retain the system, but if it be found and clearly demonstrated that extremely minute differences of potential are sufficient to cause serious damage to underground structures in urban districts, it will be necessary to reconsider the whole position, and perhaps to adopt an insulated return conductor, or else to fall back upon a battery system of self-contained cars, either of which expedients would be greatly to be deplored. The second case of earthing in order of importance is that of one conductor of ordinary lighting and power circuits, and it is on this point that the author desires to raise discussion chiefly.

It has been hotly debated, and much difference of opinion still exists as to whether it is desirable or not to earth the middle wire of a three-wire system. Let us consider what are the advantages and disadvantages of such a course. The main advantages are the following: (1) by earthing the middle conductor the extreme difference of potential that can be attained by any one of the conductors from earth is halved, and all can be handled not only with great safety, but practically without inconvenience; (2) the stress on the insulation is halved; (3) all three conductors may be taken into a consumer's premises for all pressures up to and including 500 volts pressure across the outers without contravention of the regulations of the Board of Trade — this advantage is undoubtedly by far the most important; (4) immediate notice of a leak on one of the outer conductors is given. The disadvantages of earthing the middle conductor are: (1) if a leak exists on one conductor, current is continually forced through it, thus causing in many cases complete destruction of the insulating material; (2) a leak on

Digitized by Google

one conductor produces a short-circuit on one side of the system of distribution, unless the earth connection is removable at will.

In Manchester the Board of Trade require that the middle conductor shall be maintained at or near the earth potential, and the author has now had nearly seven years' experience of this system. In his judgment there can be no possible doubt that, at all events with continuous current, and quite possibly with alternating, the effect upon the insulating material of the negative main is most severe. In operating a system of distribution by means of continuous currents, it is always found that if none of the conductors be deliberately earthed those connected to the negative pole assume earth potential; the positive conductors consequently being at the maximum potential above earth corresponding to the pressure used on the system. The reason for this is well known. It is the phenomenon known as electric osmosis, whereby moisture tends to travel away from the positive pole and towards the negative pole. Whatever system of mains be employed there are always many points at which surface leakage can take place, and whether the conductors be bare copper on porcelain insulators or be continuously-insulated cables, at every point where the conductor is exposed leakage from the negative pole will take place, but if the negative conductor be kept near earth potential this tendency will be small. If, however, the middle conductor be deliberately connected with earth so that the negative outer is kept below earth potential, a current corresponding to the amount of the leakage will be constantly forced through the leak, and the tendency for moisture to flow to the negative conductor will be maintained. If the leakage was confined to the surface of the insulation at points of connection to the conductors the result would not be so serious, but the author has found that with certain makes of rubber the material is evidently porous, and small as is the leakage current at first, it is sufficient to cause water to enter through the pores of the rubber, and the conductivity of this water so increases the leak that in course of time the whole of the rubber on the negative conductors is destroyed, large blisters forming within its substance and becoming filled with strongly alkaline liquid, almost certainly derived from the substances mixed with the rubber. The rubber is often much distended, causing the liquid to be under considerable pressure. In course of time this pressure increases to such an extent as to burst the rubber, causing a hole completely through the insulating material. It is clear that the water could not merely flow into these blisters; it is almost certainly driven in by osmosis. What happens with rubber may happen with other materials, and, in the author's opinion, there can be doubt whatever that very grave risk of breakdown of the insulation of the negative conductors is introduced by earthing the middle conductor.

As a set-off against the above inconvenience, it must not be forgotten that the insulation resistance of the positive conductors is substantially improved by earthing the middle one, but very little importance need be attached to this, since, as already stated, the negative conductor would be at earth potential if the middle one was not earthed, and the tendency to dry the positive outer would then be doubled. The only consideration that impels one to desire to earth the middle conductor is the fact that it admits of all three conductors being brought into a consumer's premises, thus enabling every installation to be balanced within itself if it be of sufficient size to render it desirable to do so. The author is convinced that the only method of effectually balancing a multiple-wire system is to carry that balancing back to every consumer except to consumers of the very smallest size, and therefore it is of great importance to be allowed to bring the three conductors into installations. Serious as are the disadvantages, this advantage is in his judgment sufficient to outweigh them, and therefore he would on the whole decide in favour of earthing the middle conductor, but if this be done it must be clearly understood that it necessitates the utmost care in protecting the mains from moisture, and the only possible system of laying them becomes the so-called solid system, in which every cable is completely surrounded by a thoroughly waterproof material, or an air-insulated system with accessible porcelain insulators at intervals, as in the Crompton system of bare copper. If it be granted that the middle conductor should be earthed, the question at once arises, should it be permanently and irrevocably earthed, or should the earth connection be capable of removal at will. The author would unhesitatingly reply, "it must be removable." The first consideration is continuity of supply, and if a leak developing on one conductor is to cause a short-circuit, the chances of interruption are increased manifold beyond what they would be if the earth connection could be removed until the fault had been localised and repaired. It is quite clear that the chances of a leak occurring on one conductor are many times greater than those of two leaks occurring on two separate conductors simultaneously. It may be argued that if the earth connection is liable to be removed, all the advantages of making it at all are done away with, since the distribution of potential will alter when it is cut off. To some extent this is true, but it must be remembered that the connection would only need to be removed for short periods and at long intervals, and, therefore, in practice but little risk would arise. If it were a question of dangerous pressures, it would be entirely different. In such case the earth connection must never be removed while the main is in use. Once it be granted that the earth connection must be removable, it becomes obvious that the conductors must be earthed at one point only, and that must be easily accessible from the generating station. This consideration shows that it is impossible to allow one of the conductors in a consumer's installation to be uninsulated, a system of wiring frequently advocated by some on account of its cheapness and some other advantages.

There is, however, another reason for not using this system of wiring, depending on the undesirability, already pointed out, of earthing a conductor at more points than one. It is often argued by the advocates of the system that the balancing wires carry so little current that the fall of potential in them is negligible. It is true that balancing wires frequently bring back but little current to the generating station, but locally it is unavoidable that these should be heavy currents, causing substantial differences of potential, flowing between the various installations, composing a balanced main, and these differences of potential may cause destructive electrolysis, and, with alternating currents, interference with telephone lines. Certain special features arise in connection with a distributing network fed from transforming sub-stations supplied with high-pressure current to which attention may be called. In a case likely to become not unusual in practice—namely, that of three-phase transmission with rotatory converters supplying continuous current to the network, it will probably be required that the grouping of the transformers shall be star and the middle point be earthed. Now, if this point, which is also directly connected to the middle distributing conductor, be earthed at the transformer, we shall have all the disadvantages of a middle conductor earthed at several points. A much more serious case will, however, arise if, in addition to this, the middle wire be opened between two sub-stations, but the outers be carried through. In such an event, the whole balancing current may be conveyed by the earth and do great damage. A similar difficulty would arise with balancing transformers distributed at various points of the network if the middle wires are not continuous throughout and an earth connection is made in the balancers. In order to comply with this condition of earthing, the middle point of the transformers, the earth should be made by connecting the middle wire to the point in question and earthing this middle wire at one point only for the whole system.

The author has made no attempt to treat this subject at all fully, his desire being merely to raise a discussion on the subject generally of connecting any portion of a distribution system to earth, the chief points being: (1) should any portion of any system of distributing conductors, whether for the ordinary supply of energy or for traction, be connected to earth; (2) if such a course is desirable, what conductor or conductors should be earthed, and at what point or points; (3) what difficulties may be expected from earthed conductors, and in what way may these difficulties be met, especially in the case of distribution for electric traction purposes.

Before the discussion was opened the Secretary read the following contribution to the same from Mr. A. P. TROTTER: In this valuable paper, the author assumes, in accordance with his own practice, that no resistance is intentionally introduced in the earth connection. The advantages and disadvantages of adding, say, one ohm, to prevent a dead short-circuit might be discussed, and it would be interesting to hear the experiences of those who use recording ampere-meters in the earthing circuit. It has been proposed to earth at the feeding points instead of at the works. Ampere-meters would have to be placed at the works in order that leaks might be noted, observing by the current passing to earth at each point, but the advantages to be gained do not seem to balance the disadvantages, the chief of which is the impossibility of cutting off the earth connection, temporarily, at short notice, in case of an accident. Lead-sheathing of cables generally constitutes a connection to earth, and electrical precautions for its protection seem to come within the scope of this paper. The advisability of keeping the lead two or four volts negative to the middle 'bus bar seems worthy of consideration.

Mr. S. Z. DE FERRANTI agreed with Mr. Wordingham that the outer conductor should be earthed in one part of the system.

Mr. SNELL said he was struck very frequently with the exceedingly small difference in the cost of two and three-wire feeders for the direct-current system. In a tender he had recently received the difference in favour of the two-

Digitized by Google

wire feeder was only 8 per cent. At St. Pancras they used to have a five-wire system, and it was found that the middle wire always was at earth potential. However, if the middle wire were earthed, it became more difficult to find a fault.

Mr. CHAMEN said that he found it advisable to earth the middle wire through a resistance, as it was extremely important that a concentric cable should not be overheated by a short-circuit. He also thought that earthing the wire tended to prevent electrolysis. Electrolysis affected the lead, but he had devised a means for ascertaining whether there were earths at any points of the system. This consisted of interposing an E.M.F. between the earth wire and its return, and noting the alteration in the earth current.

Mr. TREMLETT CARTER said that while on a visit to the United States a year or two ago he inspected a double trolley line at Cincinnati. The complication introduced by the double trolley line, in his opinion, was very much against its use. With respect to the Board of Trade limit of seven volts, he did not think that this was low enough to prevent troubles from electrolysis.

Mr. R. C. QUIN, of Blackpool, said it was very important that the middle wire should be properly earthed, in order to prevent trouble when earth occurred on one of the poles. He described a fault which had occurred in the old days in Brighton, due to the high-tension alternating current getting into the low tension mains of the continuous-current system. In Blackpool they had not found any trouble from electrolysis.

Mr. C. H. WORDINGHAM then replied, and pointed out the importance of keeping continuous records both of the current in the earth circuit and also of the direction of the same.

The discussion on Mr. Wordingham's paper being completed, Mr. Le Rossignol read the following paper:

Impressions of American Tramway Practice.

BY A. E. LE ROSSIGNOL, CORPORATION TRAMWAYS ENGINEER, NEWCASTLE ON TYNE.

When I was asked to read a paper, I thought that, having paid a visit to the United States this year, some account of my impressions of the present state of tramway engineering practice in that country might be interesting to the members of this association. The conditions governing tramway practice in America are essentially different from those prevailing in this country. On that side of the Atlantic the tramway concessions are almost without exception in the hands of companies, who in very many cases have been granted them in perpetuity, and in some cases at merely nominal rents, so that now the value of these concessions is very great. In addition, the process for obtaining leave to extend is very much simpler and quicker. There are practically no limitations set by law to any combinations or absorptions the companies may choose to make with other companies, the speed of running is very great, and the doctrine that might is right holds to an extent we would not tolerate here. Contrast these with the conditions prevailing on this side of the water: in Great Britain concessions for tramway construction take a long time to carry through and are difficult to obtain. Combinations or absorptions are jealously watched and difficult to bring about, and companies and corporations are very much hampered, therefore, in developing their tramway systems to anything like the scale which American tramway undertakings attain if successful, while the maximum speed allowed is so low that competition with railways is out of the question. Again, owing to the inherent conservatism and venerable age of British institutions, the delimitations of local authorities are very much more circumscribed and divided up than in America, so that extensions which involve trenching on the ground under the control of different and distinct local authorities involve much more difficulty in obtaining leave for extension, both to companies and to municipal authorities who may wish to extend a tramway system owned by them.

Need we wonder, then, at the great extent reached by some of the tramway systems in America, systems formed by the gradual acquisition by one master company of all the competing lines in any one city or district, till at last all the lines are under one control, and competition is entirely done away with. As you may have noticed, a typical instance of this spirit of absorption has just been completed in New York. Prior to this year there were two tramway companies in New York—the Metropolitan, which had gradually absorbed all the smaller companies, with the exception of one, and the Third Avenue Company, which owned two lines running from the heart of the city out to the Haarlem River, and beyond that owned a large extent of country lines. Early this year the Third Avenue Company got into financial difficulties over the provision of new capital to meet the heavy expenditure it incurred in converting the cable system into an underground conduit system, and the Metropolitan Company stepped into the breach, provided the capital required, and thus obtained control of the last opposition company left in New York. Latterly the American tramway world has become greatly exercised over the question of municipal ownership, the municipalities, who originally granted free wayleaves, and in some cases ground rights on the streets as well, to the tramway companies in order to get them to run lines out into the country and create new populated districts, now find that these rights and privileges granted by them are becoming very valuable, and are seeking either to get hold of the tramways again, or else to make the companies reduce the fares or pay higher percentages of their receipts to the municipal authorities. The companies are, therefore, deprecating in the Press municipal ownership, and as an argument in their favour compare the extent of the largest tramway system we have on this side under municipal control with the largest tramway system in a town in the States of a similar size, greatly to the advantage of the latter, of course. In their comparisons, however, such reasons as I have given in the first part of this paper are entirely overlooked, but there is no doubt that municipal ownership in the United States under the conditions prevalent at present in municipal circles on that side would give rise to a great deal of bribery and corruption, until in course of time a better moral condition of municipal life comes to the front. At the time the combination took place between the Metropolitan Traction Company and the Third Avenue Company in New York, the former had very nearly finished a very large power station, from which they were already supplying the lines they had converted to electric traction, and the Third Avenue Company were only laying the foundations of a still larger power station, so that the amalgamation has in this case come at a suitable time when the question of the provision of the requisite amount of power for the combined system will not be complicated by the existence of too many power stations. In most previous amalgamations of this kind in the States, of which Philadelphia is a typical example, the combined company has left on its hands a multitude of small power stations, each of which have been owned by one or other of the smaller companies it has absorbed.

Due to the fact that conversion to electric traction was just in progress, the combined company in New York is now in a very favourable position to extend its large system in the best and most economical way, and the present tendency, one might almost say the fashion, in tramway construction in America, leans towards the erection of a large central station with high-pressure distribution to sub-stations. Those companies which are hampered with a number of low-tension power stations do not, however, admit that their economical results are very greatly inferior, if at all, to those attained as yet by the larger single systems, and are in many cases providing for additional extensions by adopting battery sub-stations with charging mains to those fed by boosters. By the almost universal adoption of coal handling and storing machinery, too, the fuel costs of stations in America are kept remarkably low. As they are all owned by private companies, however, a strict reticence as to these costs is maintained, in complete contrast to the practice on this side of the water, where we are accustomed to publish full details of all working costs. As economy in current generation is greatly influenced by the expenditure on labour in the station, central-station practice in America rightly tends to the introduction of very large steam-power units, but these are all of the open slow-moving type, and so require a larger amount of attendance than would the same size units if enclosed, and provided with automatic lubrication, such as have been largely adopted in this country. A system of mechanical oil supply to these large open engines has been adopted, but if the enclosed type were made as strong in proportion and as reliable in operation as the large open type, there is no doubt that increased economy in labour would be obtained, and doubtless English manufacturers will awaken to this fact in a short time. Due to the heavy strains encountered in direct-current traction work, American steam units have gradually grown to huge proportions of the strain-bearing part, the shaft, and even though the strains probable in alternate-current work will be very much less, the same proportioned engines are being installed in the three-phase plants. Owing to the adoption of large steam units, the question of provision of adequate boiler power in a reasonable amount of floor space to correspond with the engine floor space has been met by the adoption of two or more boiler floors one above the other, surmounted by huge coal bunkers at the top, and exemplify the trust placed by American engineers in steel-framed buildings. The question of control of the large amount of electric power generated by the large units is now being taken into adequate consideration; up to the present switchboards have always been strongly suggestive of the instrument-making days, but in the new power station of the Metropolitan Traction Company the switches are built on engineering lines of generous proportions and are worked by pneumatic power and controlled electrically. Three large galleries at one

Digitized by Google

end of the engine-house are given up entirely to the switches, each in a brisk cell of its own, while the actual controlling boards take up very little space.

Underground open conduits seem to work very successfully, but have only been introduced in two cities, New York and Washington, in both of which towns no sanction for overhead wires could be obtained, and the companies had to face the heavy costs of underground conduit construction. In both towns the companies were greatly assisted in the expense by having to convert a large extent of cable traction into underground conduit, a change that is and has been carried out without much interruption of the service. Two conductors are always used and means provided for changing these conductors on to either positive or negative bars so as to enable traffic to be kept running, even with one conductor grounded in any or every section. Transformers are mostly of the air-blast cooled type and have the low-tension side directly connected, without switches, to their rotaries. These latter apparently work very well and do not give any trouble with overloading, providing no over-compounding is attempted. Compounding for a level voltage is provided for by the introduction of self-induction in the high-tension feeders and a series winding on the direct-current side of the rotary. Return-current automatic cut-outs on the high-tension feeders have been installed at sub-stations, but up to the present do not seem to be very reliable in their working. In no case, so far as I am aware, are return-current boosters used, the current having always to find its way back to the station by the rails and supplementary cables, so that even with good bonding the maximum fall of voltage from one end of a line to the station is sometimes very great. There is no limit fixed by law, and the only limit the companies recognise is an economic one when too much pressure is lost in the return circuit. A good deal of electric welding and cast welding of the rail joints has been done, and the last is looked upon, I think, with more favour. No bonds are used with this method of jointing, but if used in this country, with the Board of Trade limiting the total fall of potential to seven volts, bonds would certainly have to be provided. Overhead work in America does not compare at all with what is put up in this country, either as to strength or neatness, but in many other traction matters we have something to learn from our American cousins, especially from the way they have realised the great part electric traction plays in making adequate provision for the population of large cities; enabling poor people to live at a greater distance from their work and in better surroundings than is otherwise the case.

In conclusion, I would like to express my thanks for the kind hospitality dealt out to me by all the engineers I met during my visit.

Mr. C. H. WORDINGHAM, of Manchester, agreed with the author that there was a great advantage in having the supply of light and power in one generating works. He would like to ask the author his opinion after his recent visit as to the relative advantages of motor-generators as compared with rotary converters. He considered that the switch gear in a station was a most vital part, and thought, with the author, that the Americans paid much more attention to this detail than we did. Mr. Wordingham also raised some points as to the placing of ducts for electric lighting purposes under the tramway track, and as to the consequent electrolytic troubles.

Mr. S. Z. DE FERRANTI also remarked on the perfection to which switch gear was brought in America. In a station recently brought to his notice there were no less than two complete sets of switches, there being two switches in series in each circuit. The switches were separately controlled, so that if one failed to break the high-tension circuit, the other could be tried immediately. This seemed to the speaker to be rather complicated. He also noticed that at Niagara there had been introduced an air-blast to blow out the arc in connection with a pneumatic control. Both these points had been developed in the station at Deptford. He believed in an oil brake for switches. With regard to the capital cost of large schemes in America, he regretted to find that the outlay per kilowatt did not go down as he thought it should do. Perhaps the reason for this was the complicated transforming gear which were employed. Thus Prof. Short had assured him that he (Prof. Short) had carefully looked into the question of the distribution of light and power in New York, being provided with the actual cost of land in various parts. Prof. Short had come to the conclusion that several stations would cost less than one large station with transforming gear in sub stations all over the city.

Bailie BIRT, of Glasgow, said that in Glasgow they had started a tramway undertaking without prejudice, and he was of opinion that the tramway was in his town even more important than electric lighting. There was great need in Glasgow to get the population distributed over a larger area, and it could only be done by quick-running tramways. They had a Bill now before Parliament respecting the changes which they would make on these tramways, and also on the running speeds. They hoped to have their tramways completed for the Glasgow exhibition next year.

Mr. BRIDGES, of Eastbourne, referred to the important scheme for tramways now being considered in that town, and which would open up a large amount of land now inaccessible. He believed that in America the policy was to put down a very cheap track in the first instance, and only to construct a good track after the line paid.

Mr. LE ROSSIGNOL, in reply, said that nothing opened up the country like tramways, and it should be considered, when talking of the cost of these tramways, how small the cost was of converting a country district into a suburban one by the aid of electrical traction. Glasgow was a special case in point, where the density of population demanded some such means being adopted to relieve congestion. He gathered from his visit that there was now very little trouble with rotary converters if properly designed. After a few other remarks, Mr. Le Rossignol said he would answer other queries in writing.

Mr. R. C. Quin's paper on the protection of telegraph and telephone wires was then read.

The Protection of Telegraph and Telephone Wires in Connection with Overhead Traction.

BY R. C. QUIN, BOROUGH ELECTRICAL AND TRAMWAY ENGINEER, BLACKPOOL

This question at the present time is of special importance in view of the number of traction systems now being installed throughout the kingdom, and in view also of the fact that there is such a divergence of opinion and practice. This latter is most marked in connection with the two Government departments concerned, the Board of Trade and the Post Office. That overhead telegraph and telephone wires need protection will be admitted, but how shall this protection be best given? To the author the best method appears, and he thinks his readers will agree with him, to be the placing of these telegraph and telephone wires underground where they cross the line of tramway route. He believes the Telephone Company are not averse to this course being adopted; but we are met with the absolute refusal of the Post Office to consider any such proposition. Under these circumstances we must recognise the existence of crossing overhead wires. The most usual practice until a comparatively recent date was to place guard wires above the overhead trolley line at a distance of about 18in., these wires being of galvanised steel and supported by insulators. There is a question which the author has often asked, and to which he has not, as yet, received a satisfactory reply, and, therefore, he takes the liberty of placing the question before his readers. It is this: "What are the insulators intended for?" Are they to protect the telegraph or telephone wires or the trolley line? Assuming that we adopt guard wires, they should be supported on poles 2ft. above the trolley line, but they should not be insulated. If a telegraph or telephone wire break, what need is there to insulate from earth? If two guard wires in the same horizontal plane and 18in. apart be placed over the trolley line, the probability is that the broken telegraph or telephone wire would not come in contact with the trolley line or passing trolley; but it might do so. In that event it is better that the guard wire should be efficiently connected to earth, as a short-circuit would be the result, and if both lines, telegraph and telephone, and trolley line be properly protected by maximum-current apparatus no damage would ensue. The author would, however, point out that it is not sufficient to have these guard wires clamped to a traction post, when the traction post is bedded in concrete. There should in all cases of guard wires be two poles bonded to the rails, and these poles should preferably be the end ones of the guard-wire section. The telephone and telegraph wires should be provided with fusible cut-outs or other similar device for the protection of the terminal instruments, and this is a matter of no great cost. With these precautions there need be no fear of electrical accidents from overhead telegraph and telephone wires.

There is another system of protection now largely adopted, and which consists of fastening to the trolley line brass clips, and placing vertically over the trolley line, a wooden moulding of greater width than the trolley wire. This system, to the author, appears to have several objections. It is more

Digitized by Google

unsightly than the guard wires, and brings the trolley line into greater prominence. There also appears to be difficulty in thoroughly securing these strips, for in most towns in which they are in use many lengths have become detached. Further, they do not afford the same protection as guard wires. A telephone wire may break and fall on the strip, but so far no great damage results. A car, however, comes along, and, as has happened, the driver does not notice the fallen wire, but the cheeks of his trolley wheel touch the wire, forming contact between it and the trolley line. We then have a live telephone wire earthed only through its terminal instruments, and a live dangling wire on the car, which is not assuring to the passengers. There is a third method which is advocated by the Post Office, and that is a system of bunching telegraph wires so as to reduce the number of crossing places, and then forming an insulated cradle or hammock round these wires. The principal objection, to this course would be extreme unsightliness. It, moreover, by no means follows that if a wire breaks it will not fall through the cradle, as the meshes are 2ft. to 3ft. square. If we are to regard as impossible the laying underground at crossing places of telegraph and telephone wires, then the author suggests the following as the best method to protect telegraph and telephone wires: (1) the erection of two guard wires 18in. apart at a minimum height of 2ft. above the trolley line; (2) the length of the guard wires to be such that, should the crossing telegraph or telephone wire break close up to one span insulator and be blown horizontally in either direction, it could not, when falling, come in contact with an unguarded portion of the line; (3) each span of guard wires should be separate and distinct from its neighbour, but metallically looped across; (4) no insulators whatever should be used, but guard-wire standards be bolted direct to the bracket arms, or to the span wire, as the case may be; (5) the terminal posts of each length of guard wire should be bonded to the tramrails; (6) the trolley line should be divided into sections, and each protected by a maximum-current device—these sections should preferably not be of equal length, but proportioned for equal maximum working current; (7) the crossing span of telegraph or telephone wires should be terminated by a disconnecting insulating shackle on each side, and the connection across these shackles should be by fusible metal bridge.

If these suggestions be carried out, the author considers that all that is humanly possible to protect overhead telegraph and telephone wires will have been done.

Mr. A. S. BARNARD, of Hull, said he considered 2ft. too big a distance to leave between the trolley wire and the earth wire. Loose ends of telephone wires were then apt to swing round and short-circuit the trolley wire. In Hull he recently had all the trolley wires carefully levelled up, so that he could work the trolleys with only an 8in. rise to the stock. This enabled a much shorter distance to be maintained between the trolley wire and the earth wire. He thought that the extreme alteration in vertical height of the trolley wire above the track should be limited to 6in.

Mr. A. E. LE ROSSIGNOL, of Newcastle-on-Tyne, advised that the guard wire should be earthed through a switch in the switch pillars. It was often necessary for men to work on the trolley wire while the current was on. The earth wire was then a great danger to the linesmen. He did not believe in making the maximum-current cut-outs in the switch pillars go at any current at all comparable with the working current, otherwise a defect in one section causing a grouping of cars on the section before would most likely blow the cut-outs in that section before, and so make matters worse. He was not at all sure that a better plan was adopted in Germany of placing an earthed stirrup under the telephone wires a short distance from the post. The telephone wire then was burnt out automatically by the current passing along it from the trolley wire to earth.

One of the Glasgow Bailies then explained what an excellent system of telephones they were proposing to have in Glasgow, and that they were avoiding the troubles the author referred to by placing all the telephone wires under ground.

Mr. QUIN then replied, and pointed out that until the General Post Office were forced to put their wires underground the municipalisation of the telephones would not give the relief spoken of by the Glasgow representative.

This concluded the business of the meeting to which the Press was admitted. The afternoon on Friday was devoted to the inspection of the electric lighting and tramway systems of Leeds.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

289. What is the best method of determining the counter E.M.F. of electrolytic baths?—W. G.

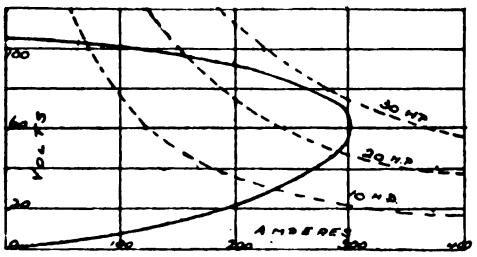
290. Give comparative figures as to the weights and efficiencies of true direct-current dynamos of about 200 kw. capacity, running at a speed of about 50 revolutions per minute, the first machine to be a two-pole one and the second a multipolar. Figures from actual machines would be of greatest service.

ANSWERS.

Question No. 283.—When two dynamos are running in parallel, each with full load, 200 amperes at 100 volts, if belt comes off one, will the extra current at lower voltage harm remaining armature if the starting lever is not moved? If so, how?

Best Answer to No. 283 (*awarded* 10*s.*).—There is not sufficient data given in the question to make it possible to give a definite answer to the particular case quoted; all that one can do is to deal generally with one or two cases under varying conditions.

In the first place, if the two machines are connected up to a common 'bus bar, there should be fuses or cut-outs of some description inserted between them and the 'bus bar, so that in the event of anything taking place which would cause an injurious current to flow from either machine, the circuit would be broken thereby before the armature could be seriously harmed. Let us assume, however, that there are no cut-outs, and that the machines are coupled directly to the bars. It is not stated whether the machines are series or compound wound. Let us suppose them first to be shunt wound, and to have characteristic curves something similar to the one shown in the figure, which was taken



from actual practice. It will be seen from the curve in question that if the resistance in the external circuit be gradually decreased, the current will increase and the E.M.F. decrease until a point is reached where the voltage drop is so rapid that it more than counterbalances the tendency of the decreasing resistance to increase the current. The result is that there is a certain maximum current beyond which it is impossible to force the machine. The worst, therefore, that could happen would be that the total load thrown upon the one machine should be just sufficient to attain this maximum; any tendency on the part of the dynamo to give out a greater current would simply have the reverse effect.

The question then becomes: Is the dynamo designed upon a sufficiently liberal scale that it will take the maximum load shown on the curve (300 amperes according to the figure) for a short time without overheating? If so, that settles the question, as far as a shunt machine is concerned. If not, there is another safeguard we may, perhaps, fall back upon which will limit the output of the

Digitized by Google

dynamo—*i.e.*, the maximum power of the engine. The dotted curves shown in the figure are H.P. curves calculated from varying values of volts and amperes. If a similar curve be plotted corresponding with the greatest output of the engine, it may, perhaps, intersect the dynamo curve, and thus further limit the current possible to be generated in the armature. Should the machines in question be compound wound, the drop in volts with the increased current would, of course, be either wholly or partly annulled by the increased magnetising current passing through the series turns on the field magnets; and in this case, if the increased load is large enough and the engine sufficiently powerful, the armature will probably burn out.

Finally, in all cases where a load of large dimensions is suddenly thrown upon a machine, there is always a chance that mechanical damage may be done either to the dynamo or engine. In one case within my knowledge it was the cause of a governor spring breaking and the consequent running away and breaking up of the engine.—W. G. MARRIN.

Answer to No. 283 (*awarded* 5*s.*).—The remaining generator would be called upon to supply more than twice its normal current, for in addition to the load of 200 amperes which No. 2 was carrying, No. 1 would have to supply current to keep No. 2 running as a motor. Of course, if such amount of current were supplied for any appreciable time, the armature of No. 1 would be damaged. In practice, however, the sudden increase of load would in all probability break or throw the belt off No. 1, and so cut it out of circuit as a generator, and the two machines would then stop. If the belt did not give way, however, No. 1 armature would not be damaged, provided the dynamo is an ordinary shunt-wound machine, for the following reasons: The great increase in current in No. 1 would cause a very large drop in its armature, thus materially reducing the volts applied at terminals of the shunt coils. Further, the armature reaction would now be so great that it would almost certainly demagnetise the field. The conditions, in fact, are such that the working point is transferred from a stable part of the external characteristic curve to an unstable part, and directly the armature current exceeds the critical value, the dynamo loses its magnetism and the volts drop to zero.

The answer, then, to the question is that the dynamo left as a generator will not be damaged, if it is an ordinary self-exciting shunt machine, but that the whole plant must inevitably shut down. A very practical example of the behaviour of shunt machines in parallel occurred in the Brighton central station some two years ago, when, owing to the burning out of an armature carrying 900 amperes, the remaining machines were so overloaded that they lost their excitation, and in 40 seconds the whole station was shut down. The total current being supplied just before the accident was 9,000 amperes at 230 volts.—E. M.

Answer to No. 283 (*awarded* 5*s.*).—When a sudden overload to the extent mentioned in the question is thrown on a running dynamo, in most cases the belt of the machine will be thrown off, or, again, if a fuse is in circuit current will be generated to blow the fuse, but beyond a temporary heating of the armature no harm will be done. From the question it is obvious that neither of these conditions are meant. If the dynamos are driven by separate engines, the engine running the overloaded dynamo will be pulled up, and will then try to take up the overload. If one engine runs the two sets no difference will be observed, for the engine will only have to take up the same load on one dynamo. The first result of such an overload on the dynamo would be violent sparking at the brushes, as the output of any dynamo is governed by the sparking limit. This sparking would cause great damage to the commutator by burning flats in the segments. The next thing would be injuring the armature conductors. When any conductor is overloaded for a time, the copper becomes very hot and damages the insulation. Of course, the flow of current in any conductor is proportional to its resistance, and armature conductors have a very low resistance, so the flow of current in them will be very great, resulting in the heating of the conductors and consequent charring of the insulation, this would mean new windings on the armature. Another result, which would not occur in slotted armatures, would be the displacement of the conductors; in every armature the magnets exert a certain pull on the conductors which is proportional to the output, hence the need of driving pegs in the smooth-core armatures. Taking off such a large current would involve a tremendous strain on the conductors, and if driving pegs were weak a stripped armature would result. I have seen armatures without driving pegs in which the winding has slipped quarter of the armature circumference through a continued strain being thrown on the machine. A bent shaft would also result if the shaft was weak. The lower voltage would not have much to do with the question, the current working the damage. In most cases a sudden overload like this would mean a new armature.—F. M. MOODY.

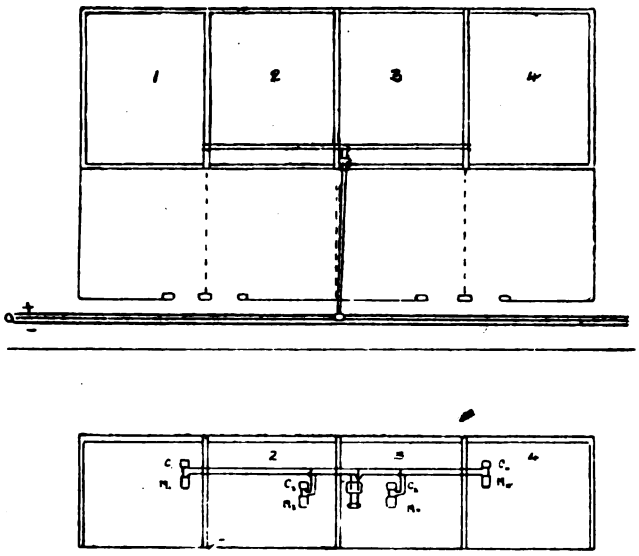
Answer to No. 283 (*awarded* 5*s.*).—The words "if the starting lever is not moved" presumably refer to the belt striking gear of the machine whose belt remains on, not being interfered with, so that this machine continues to run round. Under these circumstances, supposing the voltage remained unchanged, the current given by the belted machine would be more than double its normal full load, for it would not only have to supply the whole outside load, which was previously supplied by both machines in parallel, but it would, at the same time, have to supply a certain amount of current (say 10 or 15 per cent. of full load) to run the beltless machine round as a motor. The actual case would, however, not be quite so bad as this, for the voltage of the belted machine is bound to drop, to a greater or less extent, as soon as its load increases. If the dynamos are compound wound, this drop will be less than if they use plain shunt-wound ones; and, again, if each dynamo is driven by its own small engine, only just capable of supplying its normal full load, the speed will fall off at the overload to a far greater extent than if the two machines are driven from one engine, or from a common line of shafting, for in the latter case the total load on the engine, and, consequently, the speed, will remain almost unchanged. The result of this drop in voltage will, in practice, be that, instead of the load on the remaining machine doubling or more than doubling itself, it will not rise more than 50 to 75 per cent. above the normal, depending on the amount of drop in the characteristic curve of the dynamo and on the speed curve of the engine. With some shunt-wound dynamos having large armature reaction, it is quite possible that such an overload as the above will make the machine lose its field and the voltage die down to nothing, in which case, of course, no damage can result. In my case, however, a well-constructed dynamo should be readily able to carry the 75 per cent. increased current without burning out for at least a few minutes, by which time the lamps can be switched out or the faulty belt replaced.—Q.

Question No. 284.—Describe some good and cheap way of making connections from consumers to distribution mains, applicable where several adjacent houses take the supply.

Best Answer to No. 284 (*awarded* 10*s.*).—As the connection of consumers to the distributing mains of an electric supply undertaking is a very heavy charge against the concern, it is important that the expenditure in this direction should be kept as low as possible. Where several adjacent houses take the supply, something towards this end may be done. Let 1, 2, 3, and 4 (see sketch) be four such houses. The service box would be put on the main opposite the division wall of 2 and 3, and if an extension has been run to the houses the main would end here. A service heavy enough to deal with the demand of the four houses would be run up the garden of, say, No. 3 into the cellar, where a suitable cut-out has been fixed to receive the ends. From the further side of this cut-out leads are run through cellars 2 and 3 just into cellars 1 and 4. As the ends come through the walls, they are taken into one terminal of the meter and of the cut-out with which the wiring contractor has finished off his work. This does away with the necessity of making joints at these two points. The cut-outs are shown at C_1, C_2, C_3, and C_4, and the meters at M_1, M_2, M_3, and M_4. Tee-joints are made in cellars 2 and 3, and the branches connected into meters and cut-outs there. Each installation is pro-

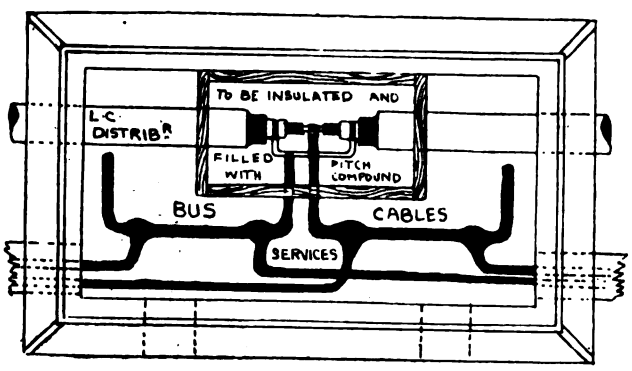
Digitized by Google

tected by its own cut-out, and the services by the main cut-out. Where there is no cellaring, as is sometimes the case in flat sandy districts, the leads can usually be run under the floors, as there is generally sufficient room underneath in which to work. If not, an occasional floorboard can be taken up without much trouble. The meters could then be fixed in the orthodox position—"the cupboard under



the stairs." The leads through the cellars may be cleated up to the floor joists, run in casing or in iron pipe, according to circumstances, care being taken in the case of an alternating supply that the two cables are run in the same pipe to obviate induction effect. If the distribution is done on the three-wire system, the block of houses may be balanced on itself. This would, however, scarcely be necessary, as the using of that system would imply the presence of actual or possible consumers at no great distance. If the system is two-wire concentric throughout, probably the cheapest way would be to take the houses in pairs. A double service box would be placed opposite division walls separating 1 from 2 and 3 from 4, and the services to the two adjacent houses run in the same trench; or a single service box might be used, and a tee-joint made in, say, cellars 2 and 3, and the branches taken through into cellars 1 and 4. Concentric services, however, mean complication, as either a cut-out with special contacts is necessary, or else the end must be finished off with some form of fork or bottle joint.—P. S. T.

Answer to No. 284 (*awarded* 5*s.*).—The sketch shows a simple method of making multiple connections from a



single joint on a concentric distributor. It is equally applicable to singles, triple-concentric, or three-core. The distributor is assumed to be of a hygroscopic character; the 'bus cable joints to it are therefore insulated with the usual well-boiled tapes, and then encased in a strong wooden box which is filled with a compound of pitch and diatrine (or bitumen) proportions about 4 to 1 respectively. This keeps the pitch from cracking, and makes it strongly adherent to all surfaces, thus preventing moisture creeping to joint. The 'bus cables should have fairly inflexible strands (to prevent sagging), insulated with vulcanised rubber of cheap quality (good-quality rubber would get spoiled by the jointing operations upon them), and the insulation is sufficiently preserved by being embedded in the compound and suspended in air. The service leads are also of cheap-quality rubber, and are laid in pitched troughing to the various consumers' premises. In the event of a considerable distance occurring between the joint and consumer's fuse (or where there is a likelihood of injury to service leads), the section of the lead might be reduced by cutting out some wires at a place as far as possible from joint (but accessible in pavement box) and reinsulating, thus providing a fusible cut-out in case of anything going wrong on the service line. A foot or so of slack should be left on service leads in the brick box. This box should have a removable cover properly caulked at the joints, and should be well ventilated by means of a gas-pipe running out from each side of box to nearest wall, and suitably bent at end to keep intrusive substances out (so-called ventilating-box covers are a snare and a delusion). This method of service jointing is cheaper and more accessible than most systems, and for a dry locality is all that can be desired. Excessive dampness that might tend to injure the service joints can be guarded against by making a clinker bottom to brick box and coating the exposed cables with paraffin wax. There are other and more expensive methods, entailing cast-iron boxes and gunmetal fittings; but they are also inelastic, so that to put in a two-service box and eventually find that four are wanted is not less vexing than to put in a more expensive four-service box at another place and to find that the original two consumers will never have company. With the system described above, a yard of 'bus cable will suffice for one or a dozen services, and scrap cable ends can be used.—J. H. C. B.

LIGHT RAILWAYS.

We have received from the Light Railway Commissioners the following statement: It is announced for the convenience and information of the public and the parties interested that the following dates have been provisionally proposed for the holding of local enquiries by the Light Railway Commissioners. Due notice, by advertisement and otherwise, will be given in the usual way when any date is finally arranged: July 23—Kingston, Surbiton, and District Light Railway, 1899, and Kingston, Surbiton, and District Light Railway Extensions, 1900; July 24—Hayling Island Light Railway; July 26—Norwich and Dereham Light Railway; July 30—Bath and District Light Railway; July 31—Bridgwater, Stowey, and Stogursey Light Railway; Aug. 1—Devon South Hams Light Railway; Aug. 3—Mid-Anglian Light Railway, 1899, and Mid-Anglian (Amending) Light Railway, 1900; Sept. 20—Rhyl and Prestatyn (Extension) Light Railway; Sept. 21—Pwllheli and Nevin Light Railway; Sept. 22—Warrington and Runcorn Light Railway; Sept. 24—Windermere and District Light Railway; Sept. 25—Blackburn, Whalley, and Burnley Light Railway; Sept. 26—Wigan Light Railway; Sept. 27—Hyde and Dukinfield Light Railway; Oct. 8—Deanhead Light Railway; Oct. 9—Nidd Valley Light Railway; Oct. 10—Durham and District Light Railway, and West Hartlepool (Extensions) Light Railway, 1899; Oct. 11—Jarrow and South Shields Light Railway; Oct. 12—Wales and Laughton Light Railway, and Barnsley and District (Extension No. 2) Light Railway; Oct. 17—Kidderminster and Bewdley Light Railway; Oct. 18—Cleobury Mortimer and Ditton Priors Light Railway; Oct. 25—Swansea and District; Oct. 26—Llanelly and District; Oct. 27—Rhondda Valley.

At a meeting of the Gloucester County Council a proposal that the Council make application to the Light Railway Commissioners for an order, under the Light Railways Act, 1896, authorising the County Council to advance £15,000 to the Witney, Burford, and Andoversford Light Railway on condition that the Oxfordshire County Council did the same, that her Majesty's Treasury made a free grant under Section 5, and that the balance required for the construction of the railway be raised by means of debentures or ordinary shares, was defeated.

A short report of the action taken by the committee appointed to oppose, on behalf of residents and ratepayers of Blackheath, the light railways schemes of the London County Council, so far as that scheme affected Blackheath, has been issued.

A communication was read at the last meeting of the Ogwen District Council from Messrs. Bennett and Ward-Thomas, of Manchester, stating that it was proposed to construct light railways from Carnarvon to Bethel, Ebenezer, and Bethesda, and from Carnarvon to Dinas Dinlle. It was decided that the question should be deferred in order to obtain further particulars.

Sir Courtenay Boyle had last week before him for confirmation the light railway orders granted by the Light Railway

Digitized by Google

Commissioners for light railways from Colne to Trawden and from Colne to Nelson and Barrowford. The Colne and Trawden line was promoted by Messrs. Greenwood and Batley, Limited, of Leeds; the Nelson order was promoted by the Corporation; and the Barrowford order by the Urban District Council of Barrowford. Sir Courtenay Boyle said he would report to the Board of Trade on all the schemes.

In connection with the scheme promoted by the British Electric Traction Company for the construction of a system of light railways in Kingston, Surbiton, and district, a public enquiry is to be held by the Light Railway Commissioners at the Assize Courts, Kingston, on the 23rd inst.

COMPANIES' MEETINGS AND REPORTS.

ELECTRIC CONSTRUCTION.

The ordinary general meeting of the Electric Construction Company, Limited, was held on Thursday week at Winchester House, E.C., Mr. J. W. Barclay presiding.

The **Chairman**, in moving the adoption of the report, said they had to deal with a profit of £21,729. It was proposed to pay the fixed preferential dividend and to distribute 6 per cent. to the ordinary shareholders, carrying £4,777 forward. The cost of maintaining the works, etc., and £5,000 to the credit of the general depreciation account, all came out of profits, as usual. For the past seven years they had applied £33,000 of profits in reducing the capital account, while the works had now more capacity for earning dividends than ever before. During the last seven years the size of the machines they were required to produce had very largely increased, but practical considerations led to the conclusion that the limit of size had nearly been reached, and the directors were of opinion that the works would be able to cope with the largest machines that would be demanded. During the past year the Company had successfully completed the equipment of the City and South London Railway extensions with plant and appliances of exclusively British manufacture. As to the future, they were full of orders, and the Board were pressing forward the completion of the new shops to enable the Company to execute them without undue delay. On the whole, their position in the manufacturing world was becoming more and more firmly established, and they might regard the future with confidence.

The motion was seconded and carried.

TELEGRAPH CONSTRUCTION AND MAINTENANCE.

The half-yearly general meeting of this Company was held at the offices, 38, Old Broad-street, on Tuesday, Sir R. G. W. Herbert presiding.

The **Chairman** said their factories had been closely employed since they met them last, doing good work, and so had the ships. The new ship "Anglia" had lately completed one voyage and was about to enter on another, laden with a greater amount of cable than had ever before been carried by any telegraph cable ship. They had work in hand which would occupy them sufficiently well during the remainder of this year, and did not anticipate that there would be any less favourable accounts to render to them when the annual meeting came round.

Mr. Croft said that there was only one subject on which he would like to make a remark, this being the Pacific cable. Probably everyone had seen an advertisement in the papers with respect to tenders being asked for on behalf of that cable. He thought it would be satisfactory if the chairman were enabled to say whether the Company was in a favourable position as regarded tendering for that cable.

The **Chairman** said that Mr. Croft was right in saying that a notice had appeared in the papers that tenders were about to be called for. They had only just received the detailed specifications, and the Board had not had time to give very close consideration to them. The proposals of the Government were that the work should be divided into sections—the long section from Vancouver to Fanning Island, and the short section from Fiji to Norfolk Island, Norfolk Island to New Zealand, and from Norfolk Island to Australia—and that tenders might be offered for those sections. A company able to do the section from Vancouver to Fanning might, if it had the means in its establishment, be able to undertake other sections also. Whether they would be able to offer to do this very exceptional work at prices which would satisfy the Australian Colonies and Canada that they ought to incur the expenditure he could not say, but they were quite sure that no other institution had a better prospect of being able to do the work, both economically and soundly, than their Company.

CALCUTTA TRAMWAYS.

The ordinary general meeting of this Company was held on Wednesday at Cannon-street Hotel, E.C., Mr. E. C. Morgan presiding.

The **Chairman** said the general condition of the Company was very satisfactory, but there had been a diminution in the receipts as compared with those in the previous year. Having regard to the wholesale reconstruction which was being carried on throughout the year, it had been a work of the greatest difficulty to maintain the service of the lines, and great credit was due to the staff in Calcutta for the relatively small inconvenience caused to the public in these trying circumstances. A large decrease of car mileage was necessitated by the practical reduction of the lines to single track during the greater portion of the year, and it was necessary to discontinue temporarily the facilities usually granted for transfer from one line to another. It was satisfactory to observe that, in spite of difficulties, the loss of traffic was inconsiderable, and that it had been possible to effect important savings in expenditure. As to the present position of the Company, when they met on Dec. 19 last the agreement with the Corporation had just been concluded. No time was lost in pushing on with the necessary surveys and plans for the new installation, and a definite contract had been entered into for the completion of the work by Dec. 31, 1901, at a cost not to exceed £170,000. He also mentioned last December that they had come to an arrangement with the Government of Bengal for the doubling of the line across the Maidan to the docks, and for its electrical equipment. This doubling was now almost complete, and had been found, even without the new motive power, to afford the greatest convenience to the Calcutta public. The contract mentioned covered the electrical equipment of this line, as well as that of all the lines now existing within the municipal boundaries, but it did not cover the cost of erecting the power-house and the alteration of the car-sheds. In order to provide the necessary funds for the heavy expenditure involved, the directors created an issue of first debenture stock for £350,000, and offered £250,000 of the amount for public subscription on March 26 last, and the Board were now in possession of ample funds for present requirements. He concluded by moving the adoption of the report, which was seconded by **Mr. C. Sanderson** and agreed to.

BRITISH COLUMBIA ELECTRIC RAILWAY.

The report of the directors of this Company for the year ended March 31 states that the net earnings, which were £33,258 for 1898-99, have now reached £40,512. The ratio of working expenses to gross earnings has fallen by 4·18 per cent., which would represent a saving of £3,554, and this amount forms part of the increased profit. The net profit for the year, after deducting expenses, amounts to £38,216, besides the balance brought forward of £189. From this the directors have provided for the payment of debenture interest, £11,250; preference share interest, £6,028. Deducting interim dividend on ordinary shares there remains for distribution £17,127, from which the directors have decided to write off a further 20 per cent. of preliminary expenses, making in all 60 per cent. now written off, and to recommend a final dividend on the ordinary shares of 2 per cent., making 4 per cent. for the year. In order to provide for the growth of the business, the directors recently made a further issue of 1,600 5 per cent. non-cumulative preference shares of £10 each.

DIRECT UNITED STATES CABLE.

The report of the directors of this Company for the last half-year states that the revenue, after deducting out-payments, amounted to £52,204, as compared with £51,951 for the corresponding period of 1899. The working and other expenses, including income tax, amounted to £20,506, leaving £31,698 as net profit, making, with £6,347 brought forward, £38,045. Three quarterly interim dividends of 3s. each per share have been declared, and a final dividend of 3s. per share is now proposed, together with a bonus of 2s. per share, making 3½ per cent. for the year. After transferring £10,000 to the reserve fund account, the balance of £3,761 on the revenue account is proposed to be carried forward.

SOUTH STAFFORDSHIRE TRAMWAYS.

The report of the directors states that the total receipts for the year amounted to £36,330. 11s., an increase on the previous year of £2,023. 4s. 8d., and the total receipts per car mile were 14·77d., as against 13·95d. The total expenditure for the year was £33,063 8s. 9d. The directors recommend that a dividend of 2s. 5d. per share should be declared upon the preference shares. The Board of Trade has renewed the steam license to April 24, 1901, and the electric license to Dec. 9, 1903. The increase in working expenses is due to the great rise in the price of materials.

The tenth ordinary meeting of the Company was held on Wednesday last at Winchester House, E.C., Mr. S. S. Schuster presiding, when the above report was presented, and a resolution "That a dividend at the rate of 2s. 5d. per share (free of income tax) be paid upon the preference shares of the Company for the year ended Dec. 31, 1899," was carried *nem. con.*

NATIONAL TELEPHONE.

The report of the directors of the National Telephone Company, Limited, for the half-year ended June 30 last, states that the income accrued in respect of the business of the half year amounts to £700,140, as compared with £602,640 for the corresponding period of 1899, being an increase of £97,500. The working expenses for the half-year, including the special expenditure of £25,013 incurred in repairing the damage caused by the snow-storm in February last, amount to £404,520, as compared with £327,497 for the corresponding period of 1899, being an increase of £77,022. The net result for the half-year is a profit balance of £227,262, as compared with £216,257 for the corresponding period of 1899, being an increase of £11,005. The rentals carried forward

Digitized by Google

for unexpired terms of running contracts amount to £733,614, as compared with £651,741 at the corresponding period of 1899, or an increase of £81,873. Out of the available balance of £178,195 shown by the net revenue account, the Board recommend the payment for the half-year of a dividend at the rate of 6 per cent. per annum on the first and second preference shares, 5 per cent. per annum on the third preference shares, and 6 per cent. per annum on the ordinary shares. The Board also propose to transfer £55,000 to the reserve fund, and to carry forward the balance of £4,325. The sum of £366,223 has been expended on capital account during the half year in the erection of 11,696 additional exchange and private lines and in the construction of underground lines. In considering the profit results of the half-year's working, it must be remembered how very adversely they have been affected by two exceptional causes—first, the large amount of £25,013 to repair the damage arising from the snowstorm in February, and, second, the considerable increase in the cost of materials and labour consequent upon the abnormal commercial activity existing throughout the country.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Bermondsey.—The Vestry invite tenders for the erection of a generating station in Neckinger, Spa-road. Tenders by 26th inst.

Manchester.—The Tramways Committee invite tenders for supply of special (permanent way) track work. Tenders by 23rd inst.

Sheffield.—The Corporation invite tenders for 12 months' supply of transformers. Tenders by 21st inst. Details in our advertisement columns.

Hull.—The Corporation invite tenders for the electric lighting installation and fittings for the Springhead pumping station, near Hull. Tenders by 23rd inst.

Manchester.—The Tramways Committee invite tenders for the electrical equipment of 150 cars. Tenders by 21st inst. Details in our advertisement columns.

Stockport.—The Tramways Committee invite tenders for 20 double-deck tramcars, complete with electric equipment for overhead traction. Tenders by Aug. 31.

Cardiff.—The Corporation invite tenders for the manufacture and delivery of 10 30 kw. transformers. Tenders by 24th inst. Details in our advertisement columns.

Darlington.—The Corporation invite tenders for the supply and delivery of arc lamp posts and brackets. Tenders by 28th inst. Details in our advertisement columns.

Southend-on-Sea.—Tenders are invited for the supply and delivery of about 1,180 tons of steel girder rails and about 46 tons of steel fishplates. Tenders by July 25.

Birkenhead.—The Corporation invite tenders for constructing and erecting a new car shed in connection with the electric tramways in Laird-street, Birkenhead. Tenders by July 24.

Southend-on-Sea.—Tenders are invited for the construction of about 7½ miles of permanent way in connection with the Southend-on-Sea and District Light Railways. Tenders by 25th inst.

Rugby.—The Urban District Council invite tenders for taking a lease of their powers under the Rugby Electric Light Order, 1898. Tenders by Aug. 1. Details in our advertisement columns.

Algemesi (Valencia, Spain).—The Municipal Authorities will receive tenders for the installation and working of the electric lighting by July 21. Specifications may be inspected at this office.

Salford.—The Corporation invite tenders for the supply, delivery, and erection of lighting cables, tramway feeders, and street lighting. Tenders by Aug. 13. Details in our advertisement columns.

Sunderland.—The Corporation invite tenders for the supply and fixing of coal-conveying plant at the electric supply station, Dunning-street, Sunderland. Tenders by 27th inst. Details in our advertisement columns.

Algenci (Spain).—Tenders are invited for an installation of public and private electric lighting. Specifications are to be obtained from and tenders addressed to the Municipal Authorities of the above place before July 21.

Hull.—The Electric Lighting Committee invite tenders for the supply and erection of five high-tension continuous-current rotary transformers, with switch gear and accessories. Tenders by 26th inst. Details in our advertisement columns.

Aston Manor.—The Urban District Council invite tenders for steam dynamo, motors, switchboard, pipework, storage battery, pumps, arc lamps and posts, travelling crane, and wiring. Tenders by 24th inst. Details in our advertisement columns.

Southend-on-Sea.—The Corporation invite tenders for the supply and erection of boilers and auxiliaries, steam generators and switchboard and cranes, feeders and distributors, line equipments, trucks and car equipments. Tenders by July 25. Details in our advertisement columns.

Islington.—The Electric Lighting Committee invite tenders for relaying York and other stone and providing new York and other stone where necessary over the conduits and mains, as required, during the three years next. Tenders by 25th inst. Full details in our advertisement columns.

Kingston-upon-Hull.—The Corporation invite tenders for the electric lighting installation and fittings for the Springhead pumping station, near Hull. Tenders by 23rd inst. Details in our advertisement columns.

Hapton.—Tenders are invited for the lighting of Hapton township with electricity from Sept. 1, 1900, to April 30, 1901. Endorsed tenders to be sent to Mr. Ed. O'Shaughnessy, clerk to Hapton Parish Council, 16, Hammond-terrace, Padiham, by 31st inst. Full particulars on application.

Glasgow.—The Corporation invite tenders for the supply of concentric and single main cables, insulated with paper or fibre impregnated with oil, bitumen, or other substance impervious to moisture, or with vulcanised bitumen. Tenders by 26th inst. Full details in our advertisement columns.

Torquay.—The Corporation invite tenders for two water-tube boilers, with superheaters, two inductor alternators and Willans engines, pipework, surface condensers, etc., extension to high-tension switchboard, wattmeters, etc., and transformers. Tenders by Aug. 6. Full details in our advertisement columns.

Blackpool.—The Corporation invite tenders for the following works in connection with tramways extension: (Section A) trolley poles; (B) cables and trolley wires; (C) boosters and switchboards; (D) storage battery. Tenders will be received for any one or more sections, but not for part of a section. Tenders by July 23.

Madrid.—The Spanish Government invite tenders, not later than Aug. 18 for the concession of a system of electric tramway lines in Barcelona. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between 11 a.m. and 5 p.m.

Russia.—Tenders are invited by the Russian Government not later than the 28th prox. for the telephone service of Warsaw, St. Petersburg, Moscow, Odessa, and Riga. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 5 p.m.

Grays.—The Urban District Council invite tenders for the supply, delivery, and erection of the following work in connection with the electric lighting of the district: (Section A) two Lancashire boilers and pipework; (B) two 100 kw. steam dynamos, with boosters and balancer; (C) fuel economiser; (D) switchboard; (E) battery; (F) travelling crane; (G) mains and street lamp fittings. Tenders by Aug. 9.

London, E.C.—Tenders are invited by the Pacific Cable Committee on behalf of her Majesty's Government and the Governments of Canada, New South Wales, Victoria, New Zealand, and Queensland for the manufacture and laying in the Pacific Ocean of 8,272 nautical miles of telegraph cables between Vancouver and Fanning Island, Fanning Island and Fiji, Fiji and Norfolk Island, Norfolk Island and New Zealand, Norfolk Island and Queensland. It is proposed to divide the whole undertaking under three distinct contracts, for any one or more of which contractors may tender. Each of these contracts will include a clause under which the contractor guarantees the good electrical condition and working order of the cables for 30 consecutive days after the completion of the laying. A fourth contract is also proposed for surveying and sounding the whole route before the cables are laid. Forms of contract, specification, and tender may be obtained of Messrs. Clark, Forde, and Taylor, 4, Great Winchester-street, E.C., at whose offices charts showing the proposed route of the cable and the positions where soundings are to be taken may be inspected. The last day for the reception of tenders is Aug. 14. They must be enclosed in sealed covers, marked "Tender for Pacific Cable," must be addressed to Messrs. Clark, Forde, and Taylor, 4, Great Winchester-street, E.C., and must be delivered by 12 noon on that day.

RESULTS OF TENDERS.

Epsom.—The London County Council have accepted the tender of J. T. Mayfield and Co., of Queen Victoria-street, at £1,665, for the installation of telephones, tell-tale clocks, fire-alarms, and call bells at the Horton Asylum, Epsom.

Grimsby.—The Corporation have decided to accept the tender of Messrs. Chamberlain and Hookham for electricity meters, and to order 50 of the smallest size and 25 each of the next two sizes, and have also accepted the tender of Messrs. Mackenzie Bros., of Edinburgh, for lamp standards, at £613. 6s.

Stafford.—The Town Council have accepted the following tenders: Chloride Electrical Storage Syndicate, Limited, Chloride storage battery containing 224 cells, and for a switchboard with instruments and switches, at £1,699; Electric Construction Company, Limited, rewinding and converting the dynamos, at £287; Willans and Robinson, Rugby, 350-h.p. steam-engine, at £1 462; Messrs. Thomas Parker, Limited, Wolverhampton, 200-kw. dynamo, at £800.

Thorp Perrow (Yorks).—The following tenders have been received for an electric light installation at Thorp Perrow, Yorks, for Mr. H. C. Allfrey. Mr. Morgan Williams, C.E., consulting engineer:

J. C. Holmes and Co., Newcastle	£2,575
Ernest Scott and Mountain, Newcastle	2,504
Cox-Walkers, Darlington	2,400
Cox-Walkers, Darlington	2,280
Bland Bros., Newcastle	2 380
Walker and Hutton, Scarborough	2.250
Mavor and Coulson, Glasgow	2 051
Mavor and Coulson, Glasgow	2 030
Mavor and Coulson, Glasgow (accepted)	1,995

Digitized by Google

BUSINESS NOTES.

TRACTION.

Garston.—The Urban District Council have decided to oppose the Bill promoted by the Garston Tramways Company.

Southend.—Electric street trams are to be introduced by the Town Council at Southend-on-Sea. About 7½ miles of track are to be laid.

Central London Railway.—We notice that it is officially announced that the date of opening of this railway to the public is to be July 30.

Burnley.—The last ordinary meeting before the Corporation acquires the Burnley and District Tramways Company's undertaking was held last week. It was stated that the transfer would probably not take place until Dec. 31.

Moss Side.—The District Council have decided to apply for sanction to borrow £12,000 for relaying the tramlines in the district, so as to make them suitable for electric haulage, and a further sum of £3,000 for repairing the sides of the rails.

Halifax.—The Tramways Committee of the Corporation have decided to push on with all speed the work of extending the tramlines to Tuel-lane Top and to Causewayfoot. It is expected that both these extensions will be open for traffic during August.

Lancaster.—A scheme is being promoted by Mr. John Gardner, of Morecambe, for the provision of an electric tramway from Lancaster to the West-End of Morecambe. Tramways electrically propelled will, it is estimated, accomplish the journey in a quarter of an hour.

Barton.—At the last meeting of the Rural District Council the Clerk read a communication from Clifton Parish Council stating that they had passed a resolution that the Barton Rural District Council be requested to approach the Farnworth District Council asking that body to continue their electric tram system through Clifton. The clerk was instructed to reply that the Council now had the matter before them.

Southern Electric Tramways.—The Earl of Morley's Committee on Unopposed Bills in the Lords dealt last week with the Bill authorising the South-Eastern Metropolitan Tramways Company to equip electrically and operate on other than the overhead system their tramway running from Greenwich to Catford, and the Bill was passed as an unopposed measure after certain amendments had been inserted.

Bath.—The Rural and District Council having received a report from the Finance and General Purposes Committee on the subject of the proposed electric trams, the suggestion that macadam up to the rails would suffice, subject to the promise to lay wood pavement down if required by the Council from two years after construction, has been agreed to, and the report adopted.

Rhyl.—The town clerk has received a letter from the secretary to the Rhyl and Prestatyn Light Railway Company, relative to the proposed extension of the electric tramway through Rhyl. The letter states that the necessary notices have been issued, and that every effort is being made to hold the enquiry at an early date in order that the scheme can be completed and in working order by April 1, 1901. The contracts for the Rhyl electric light works have been signed and sealed.

Swansea.—At a meeting of the Tramways and Electric Lighting Committee of the Corporation last week, a proposal was made that the town clerk should make the necessary arrangements for securing witnesses in support of the application to be made shortly by the Corporation under the Light Railways Act for the extension of the tramway system. Some of the members questioned whether there would be any opposition, but the Mayor said Mr. Garoke had told him the tramway company would offer the very strongest possible opposition. The necessary authority was given.

Carlisle.—The new electric tramways met on Sunday with several accidents. Thus on Sunday night one of the trolley wires fell, and the cars stopped running. Two were left standing in Lowther-street and one in Caldewgate. The current was switched off until the wire was safely fixed. An accident of a somewhat serious nature also occurred on Sunday afternoon near Caldew Bridges. Two cars were running in opposite directions on the Caldewgate branch, and at the curve the drivers found it impossible to stop, a collision resulting, throwing one car off the line.

Yeadon.—At the monthly meeting of the Yeadon District Council last week a letter was read from the Leeds Corporation stating that the Tramways Committee could not recommend the Corporation to undertake the construction of a tramway to Yeadon and Guiseley, but were prepared to extend their system to the city boundary if the District Councils would undertake the service of their respective districts or arrange with a company to do so, so that there might be a point of connection between the district and the city tramways. It was decided to call a joint meeting of the Yeadon, Rawdon, and Horsforth Councils to discuss the question.

Dundee.—The Corporation electric tramways system, a section of which has now been completed, was on Thursday week inspected by Board of Trade officials, and there were also preliminary runs for the purpose of testing the working of the electric cars. The route which has been completed extends to 1¾ miles, and in the morning the first official run took place from the High-street to the west end of the town. These initial runs were carried through without mishap. Colonel Yorke, the Board of Trade inspector, expressed his satisfaction with the working of the cars. Thereafter the party proceeded to the generating station, and approval was given by the inspectors to the Dundee system, and the necessary permission authorising the opening of the tramways system for traffic last Friday was granted. The tramways were therefore opened to the public on that day.

Southport.—On Tuesday last Mr. Alexander P. Trotter, electric adviser to the Board of Trade, held an enquiry at the town hall, Southport, into the application of the Corporation for sanction to borrow £40,000 for the purpose of reconstructing the tramways recently purchased by the Corporation from the Birkdale and Southport Tramways Company. The Town Clerk informed the inspector that the present application was with regard only to the Birkdale and Southport tramway. The portions of this tramway within the borough, forming part of the company's undertaking, the Corporation had recently purchased, and the Board of Trade had sanctioned a loan for that purchase. It had, however, been decided, subject to obtaining the necessary sanction, to equip the line electrically, and for that purpose it was necessary to apply for further borrowing powers, and for permission to use electrical power, the present order providing only for the use of animal power. The present application accordingly was, first, for sanction to use electrical traction for these tramways; and, secondly, for sanction to borrow £40,000 for the purpose of reconstructing them and putting down the electrical equipment. The Corporation were in a position to equip the undertaking, and the overhead system would be adopted subject to the Board's approval.

London United Tramways.—The House of Lords Committee presided over by Earl Rosse has just completed its labours upon the London United (Tramway) Extensions Bill. This Bill had already been passed by a committee of the House of Commons, but was again opposed by the Middlesex County Council. The Bill proposed to remove the restriction which had been put upon the company as to working a portion of their system in Hammersmith by conduit instead of overhead electric traction, and after a contest extending over more than three years with the London County Council, the company have now secured overhead traction throughout the system. They have also obtained the whole of the extensions for which they applied to Parliament, and their system will now embrace some 40 miles of route, comprising the whole of the western suburbs of London. In several instances where the company's existing terms would expire in about 11 years they have secured extensions, so that the average period of life will be upwards of 23 years. In addition, most of the extensions will have to be bought up, if at all, not upon the Tramways Act terms, but at market value as a going concern. They are now engaged in the completion of the first section of their electric system, which they will open in a few months, and they will be able to make provision at their Chiswick power station for the working of the 40 miles.

LIGHTING AND GENERAL.

Brighton.—The electric light is to be installed in the clock tower at North-street Quadrant, Brighton.

Bradford.—The Town Council have decided to borrow a further sum of £140,000 for electric lighting purposes.

Paignton.—The District Council propose shortly to apply for a provisional order for lighting their district by electricity.

Kidderminster.—On Wednesday last the Town Council decided to obtain tenders for lighting the town hall and corn exchange by electricity.

Basingstoke.—The Mayor announced at the last meeting of the Town Council that their electric lighting provisional order had received the Royal assent.

Hampstead.—The Vestry last week decided to lay extra mains at a cost of £75, and that the engineer should obtain indicators and fuse-boxes at a cost of £86.

Dumbarton.—At the last meeting of the Town Council the question of an electric lighting and traction scheme was referred to the Lamps and Fires Committee.

Aberdeen.—On a question as to the method of charging for electricity, the Town Council have decided to continue to use the maximum-demand system, as hitherto.

Epsom.—In consequence of the increased prices in materials, etc., the Urban District Council have decided to have another scheme for their electric lighting prepared.

United River Plate Telephone Co.—We gather that allotment letters have been posted in respect to the whole issue offered of 23,361 5 per cent. cumulative preference shares.

British Insulated Wire Co.—Dividend warrants for the half-year ending June 30 on the preference shares at the rate of 6 per cent. per annum, less income tax, have been posted.

St. James's and Pall Mall Co.—The directors of this Company have declared a dividend for the half-year ending June 30 at the rate of 10 per cent. per annum on the ordinary shares.

Islington.—At last week's Vestry meeting the Clerk said that the sanction by the London County Council of the Vestry's electric lighting loans of £56,261 and £13,200 was now complete.

Kingstown.—Messrs. Porte, Sykes, and Co. have informed the Urban District Council of their intention to apply to the Board of Trade for an electric lighting provisional order for the township.

Sunbury.—The Twickenham and Teddington Electric Supply Company have given notice to the Urban District Council of their intention of applying for electric lighting powers in the district.

Richmond (Yorks).—The North British Electric Lighting Supply Company have announced to the Town Council their intention to apply for a provisional order to supply electric light in the district.

Digitized by Google

Wolverhampton.—The Town Council have sealed a contract with the St. Helens Cable Company for the supply of electric lighting cables.

Cannock.—The Urban District Council have received notice from the North British Electricity Supply Company of their intention to apply for a provisional order to supply electricity in the Council's area.

Channel Steamers.—We learn that the cross-Channel steamers of the Calais-Dover service are being fitted with electric search-lights, the first vessel on which an installation has been placed being "Le Nord."

Fulham.—The London County Council have approved of the Vestry securing a loan of £50,519 to meet the expenses for the introduction of electric lighting into the parish, and the erection of a dust destructor.

Inverness.—At a meeting of the Town Council last week the scheme for lighting the burgh with electric light, which has occupied the attention of the Council for a considerable time, was formally abandoned.

Carlisle.—The Town Council have resolved to extend the electric lighting cable along Botchergate to London-road at an estimated cost of £575, and along Warwick-road to St. Aidan's Church at an estimated cost of £330.

Leftus.—The Urban District Council have received a notice from the Northern Counties Electric Supply Company of their intention of applying for a provisional order for electric lighting purposes in the district.

Coatbridge.—The Scottish House-to-House Company are extending their high and low tension cables in various streets in the town. The Town Council have decided to light certain streets with arc and incandescent lamps.

Melton Mowbray.—The electric lighting company are about to commence laying their mains. The Urban District Council have decided to repair the roads afterwards, and charge the company with the cost of so doing.

City of London Co.—The transfer books of the preference shares of the City of London Electric Lighting Company will be closed until Aug. 2, inclusive, for the purpose of preparing the interim dividend warrants.

Dover.—The Rural District Council have received notice from Messrs. Simmons and Simmons, on behalf of Mr. E. H. Shaw, that he proposed to apply next November for powers to supply St. Margaret's with electricity.

British Electric Works Co.—This Company have, we learn, appointed Messrs. Gent and Co., Faraday Works, to be their agents in Newcastle and district, and have also appointed Mr. S. Haynes as agent at Nottingham.

Incandescent Electric Lamp Co., Limited.—The employés of the "Robertson" Lamp Works held their annual excursion on Saturday last, when a party of over 200, accompanied by the staff, had a most enjoyable day at Hastings.

Anglo-American Telegraph Co.—The directors of the Anglo-American Telegraph Company, Limited, announce an interim dividend of 15s. per cent. on the ordinary stock for the quarter ended 30th ult., carrying forward £8,700.

Gravesend.—With respect to a notice received from the United Electric Light and Traction Company of their intention to apply for a provisional order to light the town by electricity, the Town Council have decided to oppose the application.

Grimsby.—The Public Works Committee of the Town Council have accepted tenders for electricity meters and arc light standards. The committee have also accepted plans for lighting the electric light station, the cost being about £250.

Change of Address.—Messrs. Welch, Fry, and Skelton, electrical and hot-water engineers, have removed from 90, London-wall, to Salisbury House, in the same thoroughfare. The firm report an unprecedented increase in their business.

Wimborne.—The North British Electricity Supply Company and the Bournemouth and Poole Electricity Supply Company have informed the Urban District Council that they intend to apply for provisional orders authorising them to supply electrical energy in the Swanage district.

Morecambe.—The Urban District Council have received the sanction of the Local Government Board for the borrowing of a further sum of £20,000 for electric lighting purposes. The Council, however, have decided to only borrow £13,000 at present, leaving over the remaining £7,000.

Esher.—Notice having been given by the Twickenham and Teddington Electric Supply Company, Limited, and the United Electric Light and Traction Company, Limited, of their intention to apply for electric lighting provisional orders for the district, the Council have decided to refuse their consent.

Tettenhall.—With respect to a communication from the Midland Electric Corporation for Power Distribution, Limited, to the Urban District Council applying for leave to instal a system of electric lighting at Tettenhall, a committee has been formed to undertake the preliminary steps for obtaining their own provisional order.

Alnwick.—The Urban District Council have decided to discuss with representatives of two electricity supply companies on Tyneside as to supplying the district with electric power, these companies having informed the Council that they intend to apply to the Board of Trade for power to introduce electrical power into the town.

Wolverhampton.—The Corporation have given notice that from July 1 the price for electrical energy for lighting purposes has been fixed at 6d. per unit on a maximum demand for an average of 1½ hours per day during the winter months, and one hour per day during the summer months, and 3d. per unit for all energy consumed in excess thereof.

London County Council.—At the meeting of the London County Council on Tuesday, it was agreed to lend the Whitechapel District Board £30,500 for electric lighting purposes. It was also recommended by the Asylums Committee that a central station for the supply of electricity and water should be provided at Horton Manor Asylum, Epsom, at a cost of £39,000.

City of London Electric Lighting Co.—The directors of this Company have declared an interim dividend on the preference shares at the rate of 6 per cent. per annum for the half-year ended 30th ult., payable 3rd prox. Royal assent has been given to the Bill of the City of London Electric Lighting Company. Under the measure the Company is relieved of the obligation to place substantial sums year by year to the various reserve funds.

Gainsborough.—At the meeting of the Urban District Council last Monday communications were read from the North British Electricity Supply Company and the United Electric Lighting and Traction Company, Limited, stating intention to apply for a provisional order for the supply of electric energy in the Gainsborough district. The matter was referred to the Gas Committee to take preliminary steps to promote an Act for lighting their own district.

Huddersfield.—The recommendations of the Electricity Committee of the Corporation that application should be made to the Postmaster-General for a 25 years' license to work municipal telephones dating from the present month, and also that the Council should be recommended to establish a municipal telephone exchange within the Huddersfield area, has been adopted by the Town Council. The proposed scheme is estimated to cost £30,000.

Dunstable.—The Town Council have received communications from the North British Electric Supply Company and from Messrs. F. T. A. Garrett and Co., giving notice that they intended to apply in the next session of Parliament under the Electric Lighting Act for a provisional order to introduce electric lighting into Dunstable. The Council have decided to appoint a committee in order to consider the question of obtaining a provisional order of their own.

New Company.—The Typewriting Telegraph Corporation, Limited, has been registered with a capital of £100,000 in £1 shares. The objects of the company are to adopt an agreement made between the Recording Telegraphs, Limited, and this company for the acquisition of certain patents, patent rights, and inventions, and to develop and turn to account the same, and generally to carry on in all or any of their respective branches the businesses of manufacturers of and dealers in lamps, wires, lines, and the general business of an electric light and power company.

Appointments Vacant.—The Huddersfield Town Council require an electrician-in-charge of the electric supply station.—The Hoylake and West Kirby Urban District Council require a competent electrical engineer to act as clerk of works, under the direction of their consulting electrical engineer, in carrying out the necessary works in connection with their electricity supply undertaking.—The Manchester Corporation require the services of a traffic superintendent.—The Bradford Corporation require a meter reader accustomed to direct-current meters. Full particulars of these vacancies appear in our advertisement columns.

Stock Exchange.—The Stock Exchange Committee have ordered to be quoted in the official list the Bournemouth and Poole Electricity Supply Company's £70,000 4½ per cent. debenture stock, and Robey and Co.'s 20,464 ordinary shares of £10 each, fully paid, Nos. 1 to 20,163, 20,174 to 20,198, 20,229 to 20,258, 20,269 to 20,402, 20,453 to 20,492, 20,503 to 20,527, 21,744 to 21,766, 21,781 to 21,802, and 21,816 to 21,817; 7,146 preference shares of £10 each, fully paid, Nos. 1 to 7,146; and £127,000 4½ per cent. first mortgage debentures of £100 each, Nos. 1 to 2,250; and have appointed July 26 as a special settling day for the first-named company's £70,000 4½ per cent. debenture stock. Application has been made to the committee to appoint a special settling day in and to grant a quotation to Callender's Cable and Construction Company's further issue of 20,000 5 per cent. cumulative preference shares of £5 each, fully paid.

Parliament.—Private Bills: In the House of Lords on Thursday week, the Plymouth, Stonehouse, and Devonport Tramways Bill, the Croydon Tramways and Improvements Bill and the London County Tramways (No. 1) Bill were read a second time, and the Wellingborough and District Tramroads Bill was read a third time. In the House of Commons the Rhymney Railway Bill was read a third time. In the House of Lords on Friday, the Bray and Inneskerry Railway and Newcastle-on-Tyne Electric Supply Bills were read a second time, and the South-Eastern Metropolitan Tramways Bill was read a third time. In the House of Commons the following Bills were read a third time: Donegal Railway, Great Southern and Western Railway, and South Staffordshire Tramways. In the House of Lords on Monday the Jarrow and Hebburn Electricity Supply, Hastings Tramways, and Belfast and County Down Railway Bills were read a third time and passed. In the House of Commons the following Bills were read a third time: Westgate and Birchington Water, County of Durham Electric Power, Lancashire Electric Power, and South Wales Electric Power; and the Caledonian Railway Bill and the South-Eastern and London, Chatham, and Dover Railways Bill were read a second time. In the House of Commons on Tuesday the South Metropolitan Electric Supply Bill was read a third time. In the House of Commons on Wednesday the Buenos Ayres and Rosario Railway Bill and the Costa Rica Railway Company, Limited, Bill were read a second time.

Digitized by Google

Worksop.—On Tuesday last Colonel Langton Coke, A.M.I.C.E., one of the Local Government Board's inspectors, held an enquiry at the Town Hall, Worksop, respecting the application of the Urban District Council for permission to raise a loan of £15,579 for the purposes of electric lighting.

Shilden.—At a meeting of the Urban District Council on Tuesday last the recommendation of the Highways Committee that application be made to the Board of Trade for a provisional order for electric lighting purposes in the Council's district was referred to the Lighting Committee.

Swindon.—Colonel J. T. Marsh, R.E., one of the Local Government Board's inspectors, recently held an enquiry into an application made by the New Swindon Urban District Council for power to borrow the sum of £7,866 for public and private street improvements, and £3,100 for electric light works.

Bishop's Stortford.—The Urban District Council have received notice of the intention of the North British Electricity Supply Company to make application to the Board of Trade for a provisional order to authorise the company to supply electrical energy for public or private purposes at Bishop's Stortford.

Bo'ness.—The North British Electricity Supply Company, South Shields, have informed the Police Commissioners that they intend to make application to the Board of Trade for a provisional order to authorise them to supply electrical energy for public or private purposes within the area of Bo'ness local authority.

Cork.—The electric lighting company having asked the Corporation to be allowed to run their lighting wires overhead to the suburban districts, the Public Works Committee last week considered the matter. Before replying definitely, they decided to ask the company where they intended to put the wires.

Cheshunt.—At the last meeting of the Urban District Council a formal letter was read from the Middlesex and Hertford Electric Lighting and Power Company, Limited, to the effect that application is to be made for powers to supply electricity for public and private purposes within the area of the District Council.

East Barnet.—The Middlesex and Hertfordshire Electrical Lighting and Power Company, Limited, have intimated to the East Barnet Valley Urban District Council, and also to the Barnet Urban District Council, that they intend to apply to the Board of Trade for a provisional order for supplying these districts.

Burton.—At the monthly meeting of the Town Council last week the Gas and Electric Light Committee reported that the manager's return showed that during the past month the quantity of electric light sold in Board of Trade units was 6,607, showing an increase of 3,181 on the corresponding month of last year.

Maidstone.—On the question of a combined electric lighting and refuse destructor scheme coming up before the Town Council last week, it was decided that the two schemes should be separate, and that application for a loan for electric lighting only should be made. The question of a refuse destructor being erected elsewhere is also being considered.

Holborn —At the last fortnightly meeting of the Guardians of Holborn Union, Mr. Putterill again raised the question of lighting the City-road Workhouse by electricity, his notice of motion being that the supply should be obtained from Shoreditch or the Brush Provincial Company, instead of generating on the premises. The proposition is to be discussed at the next meeting.

Ashton.—Messrs. Browett and Lindley, the makers of the engines, etc., complaining of the way in which the plant is being run and handled at the lighting station, Mr. Holmes, electric lighting engineer to the city of Liverpool, is to be called in to inspect the whole of the existing station plant, and report on the same to the Electricity Committee of the Town Council.

Finchley.—Notices have been received by the Urban District Council of intention to apply for provisional orders from the Middlesex and Hertford Electric Lighting and Power Company, Limited, and from the North Metropolitan Electrical Power Distribution Company, Limited. The Urban District Council have decided that the use of wireless telegraphy in connection with the fire brigade would be impracticable.

Warwick.—At a meeting of the Town Council last week, the General Purposes Committee stated that a communication had been considered by them from the British Electric Traction Company giving notice of their intention to apply for a provisional order to supply electric power for lighting and other purposes. It had been resolved to hold a special meeting to consider the question, and to invite the manager to attend and explain the views of the company.

Kilmarnock.—At a meeting of the Town Council last week it was intimated that the Secretary for Scotland had decided to hold a local enquiry with regard to the application by the Corporation for a provisional order for borrowing powers to the extent of £50,000, of which it was proposed to spend £30,000 on electric lighting and £20,000 on the extension of the gasworks. The Council resolved to withdrawn the present application for a provisional order, and to apply for a new provisional order in the autumn.

Horsham.—The Urban District Council have received a letter from the Local Government Board as to the application of the Council for sanction to borrow £15,000 for purposes of electric lighting, asking for plans and further particulars of the scheme. A letter was also received from Mr. Hawtayne, the consulting engineer, on the matter, and another communication from Mr. Hurst as to the terms and conditions for the sale of the land referred to was referred to the Electric Lighting Committee.

Burglary.—We regret to notice that on the 14th inst. the works of Mr. A. P. Lundberg, at 477, Liverpool-road, were broken into, this being the third time during the past six months. This time, however, more damage resulted than on previous occasions, as some valuable tools, etc., were taken. Mr. Lundberg has asked us to mention the matter in case clients should find their letters, remittances, or orders not receiving proper attention, and to enable them to give him particulars and avoid unnecessary delay.

Teddington.—At a meeting of the Urban District Council last week the clerk reported the receipt of notices of intention to apply for provisional orders for electric lighting in the district from the Richmond (Surrey) Electric Light Power Company, Limited, and the Twickenham and Teddington Electric Supply Company, Limited; also a letter from the Twickenham and Teddington Electric Supply Company, Limited, as to the supply of current to that and other districts. The letters were referred to the Electric Lighting Committee.

Yeadon.—At the monthly meeting of the District Council last week, a letter was read from the Board of Trade relative to the Yeadon Electric Lighting Order, 1894, stating that the Board were not aware that the Corporation of Leeds had any power to supply electricity within the Yeadon urban district, and as at present advised, the Board did not think they would be justified in further deferring the revocation of the order beyond the period referred to in their letter of Nov. 3 last (12 months). The consideration of this matter was deferred.

Nuneaton.—At a meeting of the Nuneaton and Chilvers Coton Urban Council last week a letter was read from the Local Government Board with reference to the application of the Council to borrow £16,000 for purposes of electric lighting, including the purchase of the Nuneaton Electric Company. The Board complied with the application to borrow £8,000 for the purchase of the undertaking. The Board deferred consideration of the remainder of the application until the Council had obtained the advice of an experienced electrical engineer as to the alteration of the works.

Cardiff.—At a meeting of the Electric Lighting Committee of the Corporation on Tuesday last the electrical engineer again brought forward the recommendations for extending the plant at the electric lighting station. The recommendations were part of the scheme agreed upon 18 months ago, when permission to borrow the money was obtained. The demand had increased to such an extent that by the time the new works could be obtained it would be absolutely necessary. The committee decided that steps should be taken to obtain the new machinery, and also to put in a coal conveyor.

Personal.—We are informed that Mr. W. G. Rhodes, M.Sc., M.I.E.E., has resigned his position as chief lecturer in electrical engineering at the Royal Technical Institute, Salford, in order to join Mr. T. M. Hewitt, formerly manager of Messrs. Mather and Platt, Limited, and now conducting business as consulting mechanical and electrical engineer at Tower-chambers, Brown-street, Manchester. In future this business will be carried on at the same address under the name of Hewitt and Rhodes.—Mr. A. E. Cramb has been appointed assistant electrical engineer to the Hampstead Vestry.

Edison and Swan Co., Limited.—The directors of this Company have determined to recommend the payment of a dividend in respect of the six months ending June 30, 1900, at the rate of 6 per cent. per annum on the A share capital of the Company as now paid up. This distribution, together with the interim dividend at the rate of 6 per cent. per annum, already paid in February in respect of the first half-year, will be equal to a dividend of 6 per cent. for the entire year. The dividend warrants will be posted on July 31, 1900, and the transfer books will be closed until the 31st inst.

Dorking.—A public meeting was held at Dorking last week to give the ratepayers an opportunity of protesting against the gas company in raising the price of gas 6d. per 1,000 cubic feet. This several of them did, and speeches were made in favour of leasing the provisional order granted to the Urban District Council to a company to proceed with the introduction of electric light, giving the local body the option to purchase the undertaking at a given period. The meeting passed a resolution expressing approval of the action of the Urban District Council in the proposal to make use of their provisional order in this way.

Dorchester.—In view of the fact that the North British Electricity Supply Company, the Urban Electricity Supply Company, Edmundson's Electricity Supply Corporation, and the Bournemouth and Poole Electricity Supply Company, have given notice of their intention to apply to the Board of Trade for provisional orders for supplying electrical energy within the borough, it was resolved to inform the companies that the Town Council reaffirmed their resolution of September last to apply for a provisional order themselves. Notice was given that at the next meeting a resolution would be moved that the Council take the necessary steps to obtain the provisional order.

Lichfield.—The City Council have received notices from the United Electric Light and Traction Company, Limited, and the North British Electricity Supply Company of their intention to apply under the provisions of the Electric Lighting Acts, 1882 to 1888, to the Board of Trade on or before Dec. 21 for a provisional order authorising the supply of electricity for public and private purposes within the area of the jurisdiction of the Council, and have decided that the Streets and Highways Committee shall report further on the subject of obtaining a provisional order on the part of the City Council, and of resisting the entry of these private companies to the district.

Oban.—The Town Council have decided to hold a special meeting on Aug. 14 to consider the question of introducing electric lighting

Digitized by Google

within the burgh, and if so agreed to resolve to apply to the Board of Trade for a provisional order in the ensuing session for the above purpose. A letter has been received by the Town Council from the North British Electricity Supply Company, South Shields, stating that application is intended to be made by them to the Board of Trade for a provisional order to authorise the company to supply electrical energy for public and private purposes in Oban. The Council, however, resolved that the company should be informed that the Council were proceeding with a scheme of their own.

National Telephone Co.—Replying to Mr. Henniker-Heaton in the House of Commons the other day, Mr. Hanbury stated that the amount paid by the National Telephone Company as royalty for the year ended March 31, 1900, was £134,115. The directors have recommended the following dividends for the half-year ending June 30 last, after charging £25,013 to revenue, being the special expenditure incurred in repairing damage caused by the snowstorm in February last: at the rate of 6 per cent. per annum on the first and second preference shares, at the rate of 5 per cent. per annum on the third preference shares, at the rate of 6 per cent. per annum on the ordinary shares, carrying £55,000 to reserve, and about £4,000 forward.

British Electric Traction Co.—We are informed that Mr. James Devonshire, having been appointed a member of the Committee for Associated Undertakings, has vacated the position of district superintendent for London and South Eastern district of this Company, and also that Mr. Daniel F. Sugrue has vacated the position of district superintendent for the Eastern Counties district, and will undertake certain supervisory duties for the management; that Mr. George Stevens has resigned the position of secretary, and has been appointed chief district superintendent with charge of the London and South-Eastern and Eastern Counties districts; that Mr. Charles H. Dade has been appointed secretary of the Company; and that Mr. Ernest Hopwood has been appointed districts secretary.

London Gazette.—A receiving order has been made out *re* L. Francis, 13, Corporation-street, Southwold, Suffolk, on creditors' petition. The first meeting in the estate of the above will be held on July 21 at 12.30, at official receiver's office, 8, King-street, Norwich, and the public examination on July 24 at 11 a.m., at town hall, Great Yarmouth.—Mr. L. J. Sharp, 174, Corporation-street, Birmingham, has been released from the trusteeship of T. Ford (trading as T. Ford and Co.), The Retreat, Selly Park, Worcestershire.—Mr. E. T. Pierson, 17, Hertford-street, Coventry, has been released from the trusteeship of H. J. Wimshurst, 4, Foleshill-terrace, Foleshill-road, Warwick.—An adjudication order has been made out *re* L. Francis, 13, Corporation-street, Southwold, Suffolk.

Manchester.—On Thursday week Mr. H. H. Law, Local Government Board inspector, held an enquiry relative to an application by the Corporation for sanction to borrow £189,890 for purposes of electric lighting, and £3,520 for the purchase of land for public walks and pleasure grounds. Mr. Hudson, deputy town clerk, explained that the sum which it was sought to borrow for electric lighting purposes formed part of an amount of £500,000 which it was decided by the City Council in March, 1899, to apply for. Mr. C. H. Wordingham, electrical engineer to the Corporation, gave evidence, and stated that there had been a great increase in the demand for the electric current. While the increased output in 1896 was at the rate of 31 per cent., in 1899 it was at the rate of 43 per cent. In the present year the percentage of increase was 24. With regard to the supply of electricity which would be needed for the purposes of the tramways, he mentioned that it was expected to have three sections of the tramways in operation towards the end of the present year.

Portsmouth.—The annual report of the electric light works, presented to the Town Council last week, showed that the year ending March 31 had not been so profitable as the previous one, owing to the increased expenditure for coal. During the year the committee had spent £5,616 for coal and sold 1,393,091 units of electricity, as against £3,798 spent for coal in the year before and 1,224 949 units sold. Another cause of the falling off in the net profit was that for some reason the current sold per lamp connected had decreased. This decrease of income, added to the increase in the price of coal, accounted for over £1,900. During the year they connected 7,090 lamps of 16 c.p., and although this was 192 less than the number connected during the previous year, more consumers had been connected, the figures being: 1898 9, 7,282 16 c.p. lamps connected and 413 consumers; 1899 1900, 7,090 lamps and 426 consumers. This was due to a greater proportion of domestic lighting having been reached. During the year the capital outlay had been increased by £20,277, which meant an increased contribution of £1,719 from the revenue for interest and sinking fund.

Walsall.—At the monthly meeting of the Town Council last week the Electric Lighting Committee reported that Messrs. John Russell and Co. had applied for the electric light to be extended to their works, and that the total cost would be £5,178. The committee had offered to comply with the request on a guarantee to take current to the amount of £300 a year, such guarantee being reduced annually by the amounts received from other consumers from the same main. The committee had received a communication from the Local Government Board that they would defer sanctioning the loan of £15,000 for the new transformer stations until the sites were actually decided upon, but they had pointed out to the Local Government Board that the sites could not be fixed until the points of demand were settled by the consumers, and that the work would be seriously interfered with if there were delay in carrying out the works. The report was adopted, and its recommendations were agreed to, the committee being empowered to carry out the extension work if their proposal were accepted. The Rural District Council have received a communication from the Midland Corporation for Power Distribution, Limited, announcing their intention to apply for a provisional order authorising them to supply electric power in the parish of Great Barr.

New Bromwich.—On Monday the foundation stone of some new and extensive electricity works at Black Lake, West Bromwich, was laid by the Mayor, Alderman S. Pitt, in the presence of a large company. The works are being built on the most modern principles, at an estimated cost of £30,000, and provision is being made for future extensions. This work is in the hands of Mr. R. C. Quin (electrical engineer), Mr. J. Mallin having charge of the building operations. The Mayor, in a speech at the luncheon, said they did not hold out any large promises to the ratepayers, and they must expect little or no profit from the undertaking for the first year or two, but he believed they would make a profit afterwards. In the negotiations between themselves and the tramway company they had detected a most remarkable opening for the supply of electricity, as no less than 300,000 units would be annually required to drive the trams in the borough. As their business increased they could extend the works without serious outlay. They intended not only to encourage small consumers, but to help the industries of the town. They had also obtained power to make regulations with regard to the wiring and fitting up of houses with electricity, and were determined to do all they could to protect the inhabitants from the serious dangers of bad workmanship.

Bath.—At a meeting of the Electric Lighting Committee, Mr. Metzger presented his report as to the best means of obtaining additional private consumers. His report read as follows: "The local authority to start a free wiring syndicate, consisting of local wiring contractors. The Electric Lighting Committee to employ a canvasser to get work and quote prices for wiring to consumers. The work to be sublet to local wiring contractors at a price which will pay for the canvasser's wages and expenses and still leave a fair margin of profit for the contractor. The Electric Lighting Committee to undertake canvassing and wiring, the prices for the work to leave only sufficient profit to pay for the canvasser's wages and expenses. The canvasser must be a combined wireman and business man. Local wiring contractors to have their business premises or private houses wired, and the contractor to have an amount deducted from his quarterly account equal to 1s for every 16-c.p. lamp which he has wired in private houses and connected to our mains during such quarter. Any balance in his favour to be carried forward and settled up annually; as an alternative the contractors to receive from us the same number of incandescent lamps as they have wired during the quarter returned to them for their own selling purposes. Any wiring contractor to engage a canvasser to be engaged in canvassing for electric lighting only, and we pay as a commission the sum of 1s. for every 16-c.p. lamp wired by such contractor and connected up by us in private houses during each quarter." Mr. Metzger said the idea of the first suggestion was that they should get the local wiring contractors to put their heads together and start a syndicate, as elsewhere, to wire houses free of charge, the consumer to pay back the cost either on a three years' basis or at the rate of an extra 1d. per unit. To carry out the third they would have to get powers for wiring, as they were not included in the order. Kingston-on-Thames had recently done so.

Southport.—At the monthly meeting of the Town Council the annual report of the electric lighting works was presented. This stated that Southport this year only occupied the eleventh position amongst the electricity works of the world, as against the third position last year; but it would be observed that the returns of the other towns were for last year, and when the returns for this year were made public Southport's position would be greatly improved, and would probably be the same as last year. Referring to the borrowing powers, the total amount sanctioned by the Council, including the £9,100 applied for the previous week, for feeders for the tramways, was £147,600. Of this amount, up to the end of the financial year, £100,136 had been spent; and about £20,000 would cover the expenditure up to the end of the next financial year. The estimated profit at the commencement of the year was £2,000, but the actual profit had only been £1,779. There were two or three primary causes for that reduction in the profit, the first being the great advance in the price of steam coal. The difference between the price in the estimates and what had had to be paid more than made up the difference between the estimated and the actual profits. In addition to that, a good deal of money had to be expended in making arrangements for the protection of the plant that was already running. At the commencement of the year the committee estimated that there would be an addition of about 200 consumers. The actual addition was 202. The estimated number of lamps to be connected during the year was 10,000; the actual number connected was 9,580. They also estimated an increased consumption of about 200,000 units, but the actual increase was only 106 000 units, the reason for which was that the connections which had been made were mostly in residential houses, whereas their estimates were based on the experience of the previous year, which was that the maximum required at residential houses was only about one quarter of the lamps installed. Before that the committee had always considered about one-half the lamps installed would be the maximum demand of the consumer. The Town Council have decided by 19 votes to 8 to introduce electric arc lamps into the main business streets of the town, instead of incandescent gas-burners, as at first proposed.

NOTTINGHAM ELECTRICITY ACCOUNTS.

From the accounts of the Nottingham Corporation electricity works for the year ended March 31, 1900, it appears that the total expenditure on capital account to date amounts to £166,097. 15s. 2d. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are appended:

REVENUE ACCOUNT.

Dr. Generation of Electricity.	£	s.	d.

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T. units (estimated)		1,603,579
Quantity sold { Public lamps 20,904; Private consumers 1,470,280 }		1,491,184
Quantity used on works		16,180
Total quantity accounted for		1,507,364
Quantity not accounted for (estimated)		96,215
Number of public lamps		15
Total maximum supply demanded (kilowatts)		1,578

PROVISIONAL PATENTS, 1900.

JULY 9.

12388. Improvement in or relating to mechanical motive devices for the controlling drums or switches of electrically-propelled vehicles. Alfred Julius Boult, 111, Hatton-garden, London. (Edwin R. Gill, United States.)

12391. Improvements in electric traction. Gustavus Palmer Harding, 24, Southampton-buildings, Chancery-lane, London.

12392. Improvements in clamps for holding the ends of electrical fuses or links acting as electrical conductors. Callender's Cable and Construction Company, Limited, and John Charles Augustus Ward, 24, Southampton-buildings, Chancery-lane, London.

12393. An improved case or cover for electric switches, electric bell-pushes, and the like. Albert Groves, 2, Netley street, Hampstead-road, London.

JULY 10.

12404. Safety fender or lifeguard to attach to electric cars or other mechanically-propelled vehicles. Norman Edward Godson Little, 19, Bromwich-street, Bolton, Lancs.

12434. Improvements relating to the manufacture of conducting material for electrical and other purposes. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (William Joseph Burke, Henry Andrew Kaufhold, and Thomas Russell, United States.) (Complete specification.)

12466. Improvements in the construction of rail-bonds for electric railways and in the mode of applying the same. George Gatton Melhuish Hardingham, Clun House, Surrey-street, Strand, London. (Felten und Guilleaume, Carlswerk, Actien-Gesellschaft, Germany.)

JULY 11.

12469. Improvements in vessels for containing fused salts during electrolysis. Sherard Cowper-Coles, Grosvenor-mansions, Victoria-street, Westminster, London.

12531. Positive electrode for accumulators. Constantin von Sedneff 18, Buckingham-street, Strand, London.

12532. Improvements in switches for accumulator electrodes. Contantin von Sedneff, 18, Buckingham-street, Strand London.

12537. Improvements in and relating to accumulator plates. Paul Ferdinand Ribbe, 322, High Holborn, London. (Complete specification.)

JULY 12.

12554. Appliance for generating electricity to be utilised for propelling machinery and for other useful purposes. William Sunter, 8, Calton-hill, Edinburgh.

12591. Improved device for setting fuses or cut-outs in electric circuits. Carl Christian Theodor Sohrmann and Carl Moritz Oscar Feist, 111, Hatton-garden, London.

12598. Improvements relating to driving axles for electric and other vehicles. Camille Contal, 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Jan. 6, 1900 being date of application in France.)

12603. Improvements in or relating to shades for incandescent electric lamps. Entwistle and Stephens, Limited, and Henry Joseph Stephens, 8, Quality-court, Chancery-lane, London.

12609. Improvements in testing sets for measuring insulation resistances. William Beckit Burnie, 24, Southampton-buildings, Chancery-lane, London.

JULY 13.

12624. The Parsons automatic storage battery switch. Ernest Medcalf Parsons, 10, Paragon-street, Hull.

12672. Improved manufacture of glass by electrical heating and apparatus therefor. August Voelker, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12673. An improvement in the manufacture of glass by electrical heating. August Voelker, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London (Complete specification.)

12702. Improvements in accumulators. Alexandre Antoine Riasse and Jean Joseph André Seugeisen, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12709. Improvements in electric arc lamps. Frank Michael Lewis, Norfolk House, Norfolk-street, Strand, London.

JULY 14.

12716. Improvements in electric switches. William Bourne Dale, 17, Hanover-street, Keighley.

12733. Art of reducing attenuation of electrical waves, and apparatus therefor. Michael Idvorsky Pupin, 46, Lincoln's-inn-fields, London. (Date applied for under Patents, etc., Act, 1883 Sec. 103, Dec. 14, 1899, being date of application in United States.) (Complete specification.

Digitized by Google

12735. Improved electrical railway fog and danger signal apparatus. Harry James Everatt, 142, Minet-avenue, Harlesden, London.

12739. An improved dynamo brush. Johannes Friedrich Peter Ringsdorff, 37, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on August 4.

1899.

12249. Telephone systems and apparatus therefor. Thomson and Warnford-Davis.

14250. Casings for electric light and similar cables. Arthur Hudson and Charles John Wightman.

14265. Automatic signalling apparatus for electric tramways. Wehner and Laube.

14489. Coin-controlled call-recording device for telephone systems. Gill.

14501. Electrical accumulator. Hills and Matthews.

14736. Winding for dynamos. Hurrell.

15166. Form of electrically-actuated railway signal. Langdon.

15551. Means for supporting electric incandescent lamps. Davidson.

16200. Holders for electric incandescent lamps. Oppenheimer. (Actiengesellschaft Mix und Genest.)

16600. Manufacture of earthenware troughs for carrying electric cables and analogous purposes. Nisbett.

17719. Variable-rate electric meters. Lorrain. (Macdonald.)

18335. Electrodes for arc lamps. Bremer.

18457. Guards for electric tramcars and other tramway vehicles. Tidswell.

Summer Tours.—We have received a copy of the Great Eastern Railway Company's booklet, which gives particulars of new Continental tours, going by way of the Royal Mail, Harwich, and Hook of Holland route. The booklet is very nicely got up, the illustrations being printed in colours. The reading matter describes the various ways in which passengers can reach any particular point in Holland, and also deals with a portion of Germany. The booklet is well worth procuring by those intending to take a trip to the Continent this summer.

NOTES.

"Album of Electricians."—Our Italian contemporary *Elettricità*, of 11, Via Cusani, Milan, will shortly publish their "Album of Electricians," a quarto volume, in French, containing the portraits of over 200 of the most eminent electricians of the world. The price will be 5fr., or 4s.

Electric Cooking.—We understand that an enterprising builder in New York has recently built a block of flats, in which the only provision he has made for cooking is by electric stoves. A remarkable saving of space is the result, as well as convenience. We are not told whether he has made any special terms with any of the electric lighting companies for the supply of cheap electricity for that purpose.

High-Voltage Railway Working.—The Ganz system for working electric railways by means of multiphase current has been successfully experimented with in Budapest. The system is now to be tried experimentally on the Valtelina stretch of the Italian State Railways. The length of this section of the line is about 65 miles, but we are not sure how much of it is to be equipped for the experiment.

Crystal Palace Engineering School.—We have received an invitation for Aug. 9 to inspect the various departments of the Crystal Palace School of Technical Engineering. On that day the list of certificates awarded by the examiners for the summer term will be ready, and the presentations will be made by Mr. A. T. Walmisley, the chief engineer to the Dover Harbour Board. The chair will be taken by Mr. Walmisley at noon prompt.

Electric Church Bells.—In the parish of Runwell, Essex, an apparatus has been lately erected by the rector for ringing the church bells by electricity. The origin of the invention is rather curious. The rector, finding a difficulty in obtaining bell-ringers, rung the bells for three months himself. In order to save the labour involved in performing this task, he invented the "automatic ringer," and erected the apparatus in the church tower. By connecting the machine with the electric current already in use for lighting the church and rectory, he succeeded in ringing the bells with perfect order and precision. The invention is in all respects an absolute success.

Standard Voltage.—Eight London electric lighting companies have sent a deputation, headed by Lord Suffield, to the Right Hon. C. T. Ritchie who wish to amend the Board of Trade regulation so that they could change from 100 to 200 volts by agreement with the consumer, or otherwise, by arbitration. The regulation at present says that no change shall be made in the pressure of the supply to any premises except with the consent of the consumer. The deputation consisted of the representatives of the following electric companies: the Westminster, the Metropolitan, the Chelsea, the City of London, the County of London and Brush Provincial, the Notting Hill, the Brompton and Kensington, and Kensington and Knightsbridge. The President of the Board of Trade admitted that it was a strong order for a few consumers to stand in the way of the application of the new system, but these people were within their rights, and if the Board assented to what the companies asked they would be over-riding the position which the former possessed. He would take the matter into consideration, but he urged the companies to use more conciliatory methods with their customers.

Electrical Laboratory Work.—In a paper read before the recent meeting of the Society for the Promotion of Electrical Engineering Education, of U.S.A., Prof. Aldrich maintained that training in handling electrical machinery is quite as essential as training in electrical measurements. If, he said, with all his familiarity with galvanometer work, the young electrical engineer is left to the mercy of the wireman or the operating engineer, his laboratory training has been incomplete. A knowledge of the behaviour of electrical machinery and confidence in handling electrical circuits is becoming more necessary with each widening use of electricity. The utilisation of alternating currents and the operation of alternating-current machinery constitute to-day a most interesting and important field, one with which the electrical student cannot become too familiar. It is the result of experience that students who have been given a course of electrical laboratory training involving study, inspection, illustration, and operation, have a better understanding of testing work than if they had been put at once into the latter without attention to the former. We are indebted to the *Electrical World* for the above abstract of Prof. Aldrich's paper.

The Franklin Institute "Journal."—We have received the July number of the *Journal* of the above institute, which contains an exceptionally large number of papers and reports on electrical subjects. Amongst these is a contribution by Prof. R A. Fessenden on electromagnetic mechanism, with special reference to telegraphic work. Mr. J. F. Stevens also read a paper before the institute recently on electrical measuring instruments, which paper is reproduced in the number of the *Journal* before us. The report of a special committee on an instrument known as the gramaphone grand announces that a certificate of merit of the institute has been awarded to its inventor, Mr. T. H. Macdonald. In this instrument, the chief advance on the ordinary phonograph is in the speed of the recording cylinder. The inventor claims that, by increasing the speed, the recording stylus has to cut much more gradual slopes, and hence is better able to reproduce the vibrations impressed on it. There is also an improvement made in the angle at which this stylus bears against the recording cylinder. This stylus makes an acute angle to the tangent at the point of contact. A further description of the instrument and of sound records generally is given in the *Journal* by Mr. P. Mauro.

New Cable.—The Canadian Government has at last decided to lay a cable from St. John's, Newfoundland, to Belle Isle. The work of establishing the telegraph line and laying the cable is, says the *Financial News*, arranged for at a cost of £14,000, though the Marconi system of wireless telegraphy was advocated. According to official reports the route recommended for the cable is from Pointe-aux-Esquimaux, the proposed terminus of the land line, out of the Strait to Belle Isle. Our contemporary remarks that a cable to Belle Isle is not all that is needed. Parallel lines of telegraphs along the north and south coasts of the Straits are also essential—indeed, on many grounds, are more so than the cable itself—and the Newfoundland Government has intimated its willingness to permit Canadian officials to set up the wires in the Colonial territory. The Colonial telegraphs do not now extend beyond Bonne Bay, which is 140 miles from the Straits. North of Bonne Bay the shore is practically unsettled, and it is only Canadian shipping which passes by or goes on the rocks. To Canada, therefore, the benefit would accrue of such a land line along the coast, which may be an actual fact in the near future. This land line would do quite as much to prevent shipwrecks and fatalities as the cable to Belle Isle.

St. Marylebone Lighting.—As mentioned in a recent issue, the St. Marylebone Vestry has entered into an

Digitized by Google

agreement with the Metropolitan Electric Light Company to buy that portion of the company's undertaking situated in the parish. One of the financial papers compliments the Vestry on the bargain it has made in buying this undertaking for half a million sterling. The transfer is to take place on Oct. 1, 1901, and the half million is to be paid over in 5½ per cent. vestry or borough council bonds. It would seem to us that this is equivalent to paying quite £750,000 for the undertaking. It is said by the Vestry's leaders that the income of the undertaking now shows 7 per cent. on the capital outlay. We do not know what capital outlay is here referred to, but we do know the local authority will have to spend a very large sum on an efficient generating station, and on alteration to mains, when they acquire the St. Marylebone portion of the Metropolitan Company's works. This extra expenditure, together with the purchase price, will make the capital charges heavy, and we are not sure that the district would not have been more cheaply supplied by the proposed Marylebone Lighting Company, whose Bill was recently thrown out. It will be remembered that at the expiration of the provisional order the local authority would have been able to purchase at the then value of the plant and mains only. We do not believe at the present time, if the plant and mains were taken over on these terms, they would fetch even half of the purchase price.

Proposed New Tramways.—The Highways Committee of the London County Council are at present considering what further extensions are desirable in connection with the tramways in the north and south of the Metropolis. They have arrived at a total of 28 lines, a list of which will be found in another column. They have consulted the solicitor, who says that the Council have power to promote such legislation, and have asked the Council to suspend Standing Orders so that their proposals may be considered. The length of these lines is over 28 miles—16 on the north and 12 on the south of the Thames. The estimated cost for the northern lines is about £469,700, in addition to £544,360 for street widening, while for the south it is £374,500, in addition to £449,400 for street widening, making a total of £1,837,960. It is proposed that those new lines connected with the Council's northern tramways (leased until 1910) shall, with the exception of that line in Archway-road, be constructed for horse traction, unless in the meantime effect shall have been given to the provisions in the company's lease relating to the conversion of the system from horse to electrical traction. The estimates provide for rails of sufficient weight to permit of their being used for electrical traction when that system shall have been adopted. The Archway-road line will probably be joined with the light railways which the Middlesex County Council propose to construct from that point to Finchley and beyond. A cartoon plan is in preparation showing the various proposals for the Council's consideration.

Extended Steam Trials.—It is usual nowadays to specify at least a six-hour run at full load on all steam dynamos before they are allowed to leave the manufacturer's works, and certain consulting engineers extend this run to as much as 12 hours. We notice that the consulting engineer to the Fulham Vestry has introduced a new departure in this respect, in that he has insisted on the makers of the exciter engines having one at work for a full fortnight before he would receive it. The trial, however, was not in any way comparable with the usual steam trial, and seems only to be intended to show the general performance of the engine. For instance, it was run at 80lb. steam pressure instead of at 140lb., and hence at only half load. Steam trials were not made, nor were the governors tested in the way specified, as, of course, full load could not be obtained. It seems, therefore, to us that the cost of supervising a fortnight's trial in the maker's works is out of all proportion to the information gained. When it is considered that all engines supplied to electric light stations are run on trial after erection in the central station until they have proved themselves up to specification, our objection to the extended trial in the engineer's works will be obvious. In cases where a new type of engine has to be used which is not known by the consulting engineer, it is always better for this gentleman to inspect an engine which has been doing regular work elsewhere before deciding to place the order. This inspection should give much more information than can be obtained from an expensive and inconclusive test such as referred to above.

Our Fighting Brethren.—We have recently given a few particulars of an engagement in South Africa at which a number of the Electrical Engineer Volunteers were unfortunately captured. This week a letter has arrived in London from Major Crompton which we have been privileged to see. From it a large number of details can be ascertained of the engagement, and of the defence which enabled the rest of the party to keep the Boers at bay until help arrived. The electrical engineers have been put to do ordinary civil engineering work at times when their services as lighting engineers are not required. At Vredefort they were employed on some crib reconstruction work, and it was while on this that an unexpected attack from the Boers took place and a detachment of the Electrical Engineers was captured. We understand that on of their number was sent back to the construction train to demand its immediate surrender. The message he took back from Major Crompton and the engineer in charge of the van invited the Boers to do their worst, with a hint as to their ultimate resting-place. It then became necessary to seize a ridge of rocks which was held by the Boers, and which would afford protection to the English engineers, who found the train quite untenable. The Boers retired before the bayonets could be got to work, but continued to molest the party all day. The temperature, which was several degrees below freezing point, made the situation far from a pleasant one. We are glad to be able to congratulate the parties on holding their own. After the excitement of such work as this, electrical contracting in England will hardly be appreciated by members of our Electrical Engineer Volunteers. We are sure from the tone of Major Crompton's letter that the skirmish up to the ridge and the defence of the same was thoroughly enjoyed by those who took part.

Electrostatic Lines of Force.—Mr. F. J. Rogers describes in the *Physical Review* an electrostatic needle to be used for the exploration of electrostatic lines of force. When teaching students electricity, it is always advisable to show them experiments which give a physical representation of the phenomenon which has to be mastered. For instance, with lines of magnetic force, the students can easily produce for themselves with paraffined paper and iron filings the contour of the lines of force round any system of magnets. In order to do the same thing with electrostatic lines of force, Mr. F. J. Rogers tried to suspend an elongated dielectric by means of a fibre in the field to be studied. He did not find this satisfactory, but prefers an electrostatic needle which consists of an aluminium wire equipped with a gilt pith ball at either end. The needle is mounted on an horizontal axis. By the aid of this needle it is easy to show the following characteristics of electrostatic fields: (1) that lines of force are normal to the surface of a

Digitized by Google

charged conductor (an elongated cylinder, for example); (3) that lines of force are not normal to the surface of a hard rubber rod, one end of which has been charged by friction; (3) that in the case of two oppositely-charged conductors placed near each other the lines of force issue from one conductor, curve over, and end on the other; (4) that in the case of two similarly-charged conductors the lines of force from each leave it normally and pass out into space, none of them passing from one conductor to the other. A much more useful form of electrostatic needle is constructed as follows: In place of the aluminium wire a small rod of hard rubber is used. It is mounted on a shaft and provided with pith balls, as in the first form. The pith balls are oppositely charged by contact with the poles of an electrical machine. While so charged, the electrostatic needle behaves in an electrostatic field just as a magnetic needle does in a magnetic field.

Unexplained Phenomena.—There have been for years certain actions of light on metallic surfaces which have not been explained on theoretical grounds. Amongst these are the actions of light noted by Moser from 60 years ago. We gather from the columns of *Nature* that Major-General J. Waterhouse, I.S.C., has during the last year been investigating the phenomena first recorded by Moser. From these investigations he confirms Moser's results as to the production of a change on the surface of metallic silver by exposure to light that can be demonstrated by the condensation of a vapour such as mercury upon it. But he has gone further, and demonstrated the change by the deposition of silver from solution, after the manner of the development of an exposed wet collodion photographic plate. By some half-hour's exposure in bright sunshine "printed out" images were obtained—that is, images visible without any subsequent application of a developer. General Waterhouse shows that these results are not due to pressure against the mask or stencil-plate used, nor to the emanation of vapours from it, nor to heat. Usually blue light gives a much stronger effect than red, but in one experiment, when the exposure was for three hours to bright sunshine, the effect was reversed, and the patches under red, orange, and yellow glasses were developable, while those under the blue and violet glasses were not. But when the silver plate was heated to redness, quenched in dilute sulphuric acid, washed and dried, and the cut-out design was also warmed before use, the effect produced by light was so small that it seems doubtful whether there was any effect at all. On the other hand, if the silver plate was exposed to the fumes of certain substances, especially nitric acid, it was rendered very much more sensitive. General Waterhouse, in his communication to the Royal Society, states that he hopes to continue the investigation this summer, and invites others to extend the observations that he has described.

Coal-Weighing.—The question of weighing the coal in the central station is of great importance, and can be looked at from two points of view. In the dealings between the central station and the coal merchant a check weighing is required when the coal is delivered, in order that the central-station authorities may get all the coal they pay for. We do not mean by this that contractors would go out of their way to defraud the consumers, as we know that such is not the case as a rule, but there is a distinct inducement for the contractors' servants to supply themselves with coal out of the quantity which should go to large contractors, who are not likely to miss small deficiencies. In order to weigh the coal which is coming into the station, an automatic recording machine can conveniently be used, so that both the weighing and the entering of the coal on the sheet is independent of manual labour or inaccuracies. When the coal has passed through this machine and is delivered, usually by means of a conveyor into the coal bunks, a new need for weighing occurs. It is exceedingly important that the engineer should know not only how much coal is used each week to keep his station running, but also how much coal is used each shift, so that comparisons can be made between the efficiency of the different members of the boiler-room staff and also of the calorific value of the coal. We notice in an agenda of one of the local authorities of London that their engineer proposes to instal only one weighing machine, with the first object mentioned above—*i.e.*, the checking of the coal as it comes into the works. We consider that the checking of the coal on to the boiler-room floor is, if anything, more important, and that an automatic recording weigher or coal measurer should be placed on each shoot from the bunks to the hoppers of the mechanical stokers. The quantity of coal used in the furnaces of any one boiler is then ascertainable, and gives after a year or so's experience a fair indication of the correct period of time at which to clean the same.

An Adjustable Capacity.—It is sometimes convenient, when experimenting on electrical phenomena, to have a condenser the capacity of which can be varied gradually over a wide range. This has usually been done to a limited extent by taking out connections from a number of the tinfoil sheets, and also dividing the condenser up into sections. The variation in this case cannot be made conveniently without interruptions to the experiment, which is sometimes most inconvenient. In the July number of the *Physical Review*, Mr. Lyman J. Briggs describes a new form of condenser which can be adjusted for capacity without the above objection. It consists of a number of sheets of brass which are curved with a radius of from 6in. to 8in.; in fact, the curvature which is always found in thin brass sheet from being rolled up is quite sufficient for the purpose. The insulation used between the sheets is mica. The brass sheets are so placed with the curvature first in one direction and then in another, that the air space between them can be varied very much by the pressure which is applied on the two surfaces of the pile. The brass sheets are held in the correct positions relative to each other by four rods, which pass through holes at the four corners of the condenser. The brass plates make connection with these rods. There are only two holes through each brass plate, which are of such a length that while they thread on to one pair of rods they leave a good clearance between the end of each plate and the other two rods. The range in capacity of these condensers can be gathered from the following figures: A small condenser, consisting of 13 plates on each side, the plates being about 2in. by 3½in., had a capacity in air of 0·055 of a microfarad when compressed, while its capacity was only 0·013 of the microfarad when the screw used to compress the plates was slacked back. This ratio, giving a variation of over 400 per cent., has been exceeded by other types made on the same general lines. The author also gives interesting curves which show the relation between the over-all thickness of the condenser and its capacity. It seems from this that the connection between the two is by no means a straight line, as might be expected.

Employers' Liability.—The *Western Electrician* comments on a curious lawsuit, in the States, in which a man brought action against an electric light company for damages for injury arising from being struck in the eye by a piece of carbon thrown by an employé of the company while the latter was engaged in the performance of his work. The case was recently reviewed by the Supreme Judicial Court of Massachusetts. The Court overruled the exceptions to a judgment for the plaintiff. The jury had been

Digitized by Google

instructed that if the carbon was thrown by the employé for the purpose of carrying out and performing his duty in his employment, the company was liable, and, on the other hand, if the carbon was thrown by the employé to carry out some whim of his own, in accordance with some impulse of his own, and not for the purpose of carrying out or accomplishing the purpose for which he was then and there employed, the company would not be liable. This, it is held by the Court of last resort, correctly stated the law on the subject. That the carbon was thrown by the employé in the performance of the work he was hired to perform there was ample evidence, the Court thinks, in that it was shown that he was hired to remove the remains of the four carbons left in the lamp in question during the preceding night; that he testified that he ordinarily dropped the discarded pieces near the base of the lamp-post, or, if there was any reason why he could not drop them there, tossed them out into the street, intending to be careful not to drop them on a passer-by or to strike any horse in the street; that on this occasion the cart which he used was left standing at the foot of the pole on which he was at work, and that the man was struck as he was driving by, just outside of the cart mentioned. Nor does the Court consider that the situation was changed by the fact that the employé testified that he threw the piece of carbon at the man's team because he wanted to attract his attention, so as to speak to him, and did not throw it for any purpose connected with the business he was engaged in, not for any business of the company. It says that it would be strange if the jury were not at liberty to disbelieve the testimony of one employed by the company as to his mental processes. It also says that it was proper for the jury to take into consideration the fact that not only was the witness at the time of the trial in the employment of the company, but also that he had been taken back into its employment only two weeks before the trial. Besides, it says that the jury may have also believed that, from the terms in which his testimony was couched, it was evident that the witness had a particular knowledge of what the law required to exonerate the company from liability.

Electric Ore Transporters.—The *Electrical World* of New York publishes an interesting article on the application of motors in the Ohio Works of the National Steel Company at Youngstown. Amongst the electrical features of this yard are two enormous travelling bridges, which can be moved alongside of the works over a large space devoted to the storing of ore. On these travelling bridges run transporters, which take the ore from the trains and drop it on to the storage ground. The freezing up of the great lakes in winter renders this storage most necessary, as throughout the winter the works are dependent on the reserve ore accumulated throughout the summer. There are two of these mammoth bridges now in operation, and a third is to be constructed; all to operate over the same yard, which will easily hold 1,500,000 tons of ore. Each ore bridge is operated by two 130-h.p. General Electric motors geared together and to the various friction drives, which throw in or out the drums for moving the bridge cars or for hoisting the scoop bucket, or giving its carriage a cross travel, or the bridge itself a longitudinal travel up or down the stock-yard. These two motors are compound-wound, with but a light shunt coil—*i.e.*, they are practically series motors with comparatively weak shunt coils, the shunt coils having one-half the ampere-turns of the series coils, these shunt coils being intended to prevent the motors from running away when all the clutches are off. Under this condition the motors run up to a speed of 920 revolutions per minute. The motors are controlled by a G. E. L-14 controller, no reversing arrangement being needed, the L-type being used instead of the K-type. With compound-wound motors this short-circuit would pull a heavy current through the series coil to balance the magnetising effect of the shunt coil, retarding the motion of the motors severely on the transposition points, causing sparking, flashing, and other troubles The electrical motors used to drive these bridges and transporters are supplied at 250 volts. The ore comes from the ports on Lake Erie in the usual ore cars; each of these is separately pulled by a dolly car to a dump, in which the body of the car is firmly gripped, and the whole car, trucks and all, is then turned over, delivering its contents into what are termed "bridge" cars, four of which are mounted on a transfer car. These transfer cars, carrying four bridge cars each, are then hauled by a steam locomotive down under the end of the ore bridge, which takes the bridge cars, one at a time, from the transfer car and runs them out on the bridge and dumps them over the stock-yard. Each ore bridge is designed to carry 100 of these bridge cars, holding 17½ tons each, per day of 10 hours. Powerful searchlights are fitted so that the ore bridges can be worked night and day when necessary. Our contemporary gives the full details of the equipment and methods of control.

Municipal Trading.—Some interesting contributions have been made to the evidence on municipal trading during the past week. Amongst the witnesses called before the Committee on Municipal Trading was Mr. George Livesey, of the South Metropolitan Gas Company. With respect to the municipalisation of gas, Mr. Livesey advocated that if this were done, the supply should be given at cost price. With respect to the breaking up of the streets, and the consequent public inconvenience, Mr. Livesey showed that corporations were, as a rule, more lax than companies in the management of their men, and hence that the streets were likely to be longer open than if the work was being done by a local authority. With respect to the monopoly question, Mr. Livesey's opinion is that there is no more tyrannical monopoly than a corporation department which fears no man except trade unionist voters. This too great subserviency to the trades unions has been repeatedly shown n the history of m unicipal trading as far as electrical lighting is concerned. The other objections to municipal trading which Mr. Livesey clearly puts before the committee are the inability of a municipal committee to recognise and a disinclination to adequately reward merit in the higher ranks of their officers, a lack of enterprise in taking up and developing new system, and a grasping at profits to be used for the reduction of rates. These views by a successful organiser of a large company ought to carry great weight both with the committee and with the House of Commons when considering the committee's report. Unfortunately, to echo the gist of one of Mr. Livesey's expressions, the committee members, and also the members of Parliament, fear no man, but they have to meet their voters shortly, and amongst these voters there are 10,000 trade unionists for every successful organiser as represented by Mr. Livesey. Lord Avebury's views on this subjects are given in the *Contemporary Review*, showing many objections to which not a few of the proposals of widening the scope of municipal enterprise are open. He reminds us that the old school of Radicals were strongly opposed to any form of trading by governments and municipalities, which principle the new Radicals have deserted. Among the varied businesses Lord Avebury suggests that municipalities should undertake, he mentions the manufacture of electrical fittings and of the residual products of gas. He concludes with three suggestions: (1) that no extension of municipal

Digitized by Google

trading for purposes not yet sanctioned should be permitted, except after full notice and special parliamentary enquiry; (2) that as regards water, lighting, tramways, and telephones, fresh undertakings by municipalities should only be sanctioned if it can be shown that there are special reasons why they should be carried on by the municipality rather than by private enterprise; (3) that any ratepayers objecting should have a right to be heard, and give their reasons for opposing the Bill. These suggestions will not be appreciated by the megalomaniacs and collectivists; but it is high time that the public should be made to hear both sides of the question, and we welcome Lord Avebury's contribution to their enlightenment.

The Theory of the Coherer.—Messrs. K. E. Guthe and A. Trowbridge contribute a valuable article on the above subject to the July number of the *Physical Review*. After giving a brief *résumé* of work done by other experimenters and also of past theories on the subject, the authors proceed to describe their own original investigations and to analyse them by means of curves. Their conclusions on the subject, in which they attribute the high original resistance of the coherer to the film on the surface of the metallic particles, are as follows: "Dorn has shown that very little or no coherer action takes place between surfaces of the noble metals when they have been heated in a vacuum so as to expel as far as possible the surface film. He also found a decided decrease of resistance for other metals. Aschkinass, on the other hand, tried to remove the surface film from the filing particles in a tube by exhausting and heating, but did not observe any change in the behaviour of the coherer. He admits himself, however, that this can hardly be considered a decisive test. The fact mentioned above, that metallic surfaces after thorough cleaning do not show a high contact resistance, is also in favour of our supposition, and we believe that Auerbach's results can easily be explained by the rubbing away of the films by mechanical action. The films must form a sort of protecting layer on the metal surface, as the following experiment shows: Two coherers, consisting of one contact each, were put in parallel and the circuit closed through them. The resistance of each was measured before and after lowering, and it was found that coherer action took place in one only. After standing a day this one was always oxidised, while the other showed a bright surface where the balls had been in contact. The coherer action had apparently destroyed the protecting film of the one in which it took place. Aschkinass mentions his interesting results with coherers consisting of PbO_2 or CuS particles as a proof against Lodge's theory. They behave in the opposite way from the ordinary coherer. We would suggest, in view of the similarity with polarisation, that the compounds are in this case broken up into two components, one of which conducts well and the other poorly. No actual metallic contact need then occur, and the S or O mould would play a decided *rôle* in the increase of the resistance. It seems that particles of any conducting substance may form a coherer—among others, carbon. This suggests an interesting question in connection with the electric arc. Ayrton and Perry found that the difference of potential between the two carbons of an arc lamp was independent of the current strength, provided the distance between them was kept constant—*i.e.*, the apparent resistance of the arc was inversely as the current. Does this correspond to the horizontal line of our curves, and does cohesion play any part in the starting of the arc? We offer the foregoing considerations merely as a tentative explanation of this little understood phenomenon, being well aware that some of our assumptions are somewhat crude, but hoping, nevertheless, that they may lead to a fuller understanding of the subject, since they seem to furnish a satisfactory hypothesis."

St. Pancras Lighting.—We had in a recent issue to seriously complain of the way in which the *Journal of Gas Lighting, Water Supply, etc.*, commented upon the electric lighting undertaking by the St. Pancras Vestry. We find it exceedingly difficult to believe even in the good faith of our contemporary, and if we grant it good faith, we have at the same time to credit it with gross stupidity and an utter want of reasoning power. We should not have again referred to the matter but for the fact that in the issue of July 24 further remarks are made. In this, a further criticism of the St. Pancras undertaking, the cost per unit for generation is stated to be 2·66d, whereas the cost of coal per unit was 0·92d. Our contemporary adds: "This fact ought to be enough to explain to silly persons in technical colleges and on local authorities why dearer coal does not hit the electric lighting business so hard as it does gas manufacture." If our contemporary wishes to be sarcastic, it should guard itself against throwing stones without laying itself open to a serious counter-charge. We quite grant that in St. Pancras the cost of coal is only about two-fifths of the total cost of generation, but this ratio is not so exceedingly different from what is found from gas undertakings. We have taken the trouble to look up the accounts of the South Metropolitan Gas Company for the past half-year. In these we see that the whole cost of generation, including coal, oil, labour, and repairs, was £512,000. Of this total coal cost £343,800, which would seem to prove our contemporary's view of the case. Looking, however, on the other side of the balance-sheet, it will be seen that the residual products obtained from the carbonising of the coal brought in about £247,000. The labour for working up these residuals is included in the cost of generation. It is obviously unfair not to consider these residuals, and our view of the case is that the difference between the cost of the coal and the income from the residuals gives the item corresponding to the cost of fuel with an electric lighting undertaking. This cost in the case of the South Metropolitan Gas Company is, roughly, equal to £97,000. In the same way, deducting the income from the residuals from the total cost of generation, we obtain an approximate sum of £265,000 as the total cost of producing the gas. It will then be seen that the ratio of this figure, which corresponds exactly to the cost of generation in an electric lighting station to the net cost of fuel, is practically the same as that which applies in the figures from the St. Pancras electricity works. Our contemporary may answer that the cost of gas residuals will not go up with the increased cost of coal. These costs are, however, increasing, and even if the increase is not as rapid as that in the case of coal, it is likely to be also slower in coming down afterwards. It is, of course, too much to expect our gas contemporaries to take an outsider's view of the problem, and the matter is one which can well be left in the hands of the gas consumers. Our contemporary justifies the gas companies in the large increases they are making in the price of gas, and it will be amusing to read its justification of the same directors a year or so hence when they advocate decreased prices and decreased dividends in order to prevent gas businesses falling off. Reverting to the St. Pancras figures and the criticisms thereon by our contemporary, we would advise it to get the office boy to repeat to its editorial staff the above sentence at half-hourly intervals. "A municipal undertaking which serves ratepayers at cost price is a failure." It will be observed that Mr. Livesey does not hold these views.

SOUTHPORT ELECTRIC TRAMWAYS.

A brief notice of the official opening of the Southport electric tramways appeared in our issue of July 20. We now propose to give some further details of the scheme. It is about 27 years ago since the first tramways were started in Southport, the line of the Southport Tramways Company from Birkdale to Churchtown being opened about that time. Subsequently another company, the Birkdale and Southport Tramways Company, was formed to construct a line to Kew Gardens, and this was opened about 19 years since. New districts have since sprung up, and the tramways inaugurated last week are the practical outcome of a commendable policy on the part of the Southport Corporation to supply the same with a better service of trams than the older districts. Blowick, the district served by the new electric tramways, is of modern growth, having been a detached hamlet 19 years ago. To give an idea of the Corporation's previous connection with the tramways of the town, it may be mentioned that in 1896 they purchased the lines of the Southport Tramways Company within the borough, together with the buildings, and the cars in connection with the same, for £17,000, at the same time granting the company a lease for 21 years at a rental of £2,700 per year. In January of the current year the Corporation bought the lines of the Birkdale and Southport Tramways Company within the borough, with their cars, sheds, stables, and other property, for £12,000. No lease was, however, granted the company in this case. As reported in our issue of July 20, a Board of Trade enquiry was held last week into the application of the Corporation for sanction to borrow £40,000 required for the reconstruction and electrical equipment of these newly-acquired lines. It is intended to lose no time in getting on with the work when once the permission is forthcoming.

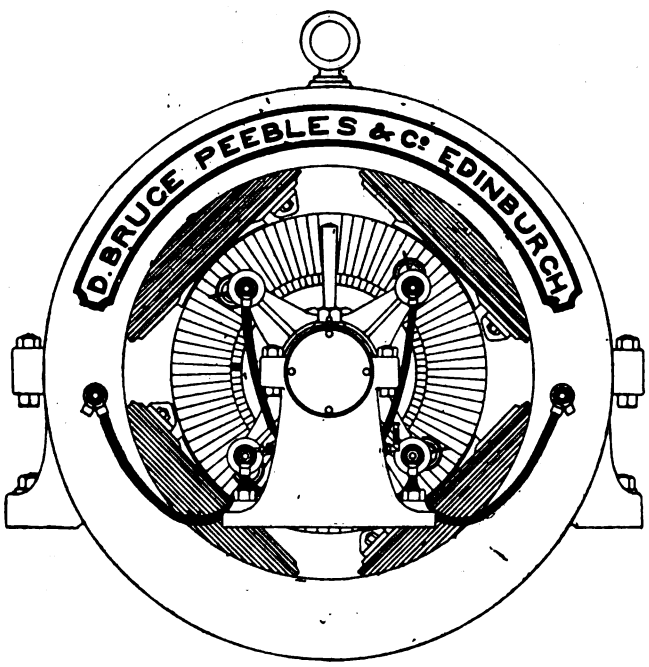

FIG. 1.—Traction Type Generator, Southport Tramways.

The new lines serving Blowick, with which we are now concerned, were first mooted in 1897. At that time Councillor Hulme was chairman of the Tramways Committee, and that gentleman, together with Councillor Travis (the present chairman of the committee) were deputed to report upon suitable roads for tramways and the best means of working the same. Subsequent to the appointment of Councillor Travis as chairman of the Tramways Committee, the report of the sub committee recommending to the Council the construction of the lines opened last week was duly carried. It was not, however, until 1899, after a great waste of valuable time, that the provisional order consenting to these lines was finally confirmed by Parliament. No time was subsequently lost in proceeding with the work. The order was confirmed in October, 1899, and contracts were signed in December of the same year, the actual work being started in January of the current year. Hence, the new lines, having a length equivalent to six miles of single track, have taken about six months to construct and fully equip. There are yet one or two small link lines to construct in connection with these tramways, besides which the Bill before Parliament this year provides for the construction of another three miles or so of track. In addition, there are already about nine miles of horse lines within the borough, including the lines to be converted for electric traction, so that eventually Southport will be in possession of about 18 miles of tramways, which gives one mile to every 2,900 inhabitants.

The power for working the new lines is obtained from the electricity works, which supply the town with current for lighting purposes. These works are situated in a central position relative to the various termini, but the generating plant installed for lighting purposes being of the alternating-current type, it has been necessary to put put down separate plant for the tramways. This special traction plant consists at present of two generators of the type shown in Figs. 1 and 2. They are of Messrs. D. Bruce Peebles and Co.'s standard No. 19A size. Each generator is capable of developing 380 amperes at 500 to 550 volts terminal potential when running at 350 revolutions per minute. As will be seen from the accompanying illustrations, the machines are of the multipolar slot-wound drum-armature type, fitted up on spiders of rigid design and ventilated throughout, and the field magnets are compound wound. The poles are of best annealed cast steel, fitted with the makers' patent "P. P. P." pole-tips for ensuring sparkless reversal at all loads. Special attention has been paid to the mechanical and electrical design of the machines to enable them to run with a minimum of attention during the widest variations of load. The efficiency of each combined set at full load (200 kw. at 350 revolutions) is over 89 per cent. The engines, to which the generators are directly coupled, are of Messrs. Belliss and Morcom's E C /12 size, capable of giving 375 b.h.p. with a pressure of 130lb. per square inch at the engine stop-valve, condensing at a speed of 350 revolutions per minute. The steam consumption of each set per kilowatt-hour, with 130lb. steam pressure 100deg. superheat, is 28·b. Steam is provided from the adjoining boiler-house through the range, which feeds the rest of the plant in the station. A special feature of the set is the exceedingly compact arrangement of the combination, the size of engine and dynamo being exceedingly well proportioned. As one of the 200-kw. sets was standing by the side of a horizontal compound engine, direct-coupled to a flywheel alternator running at a speed of 90 revolutions per minute, with an output of 125 kw., it was of interest to note that the 200 kw.

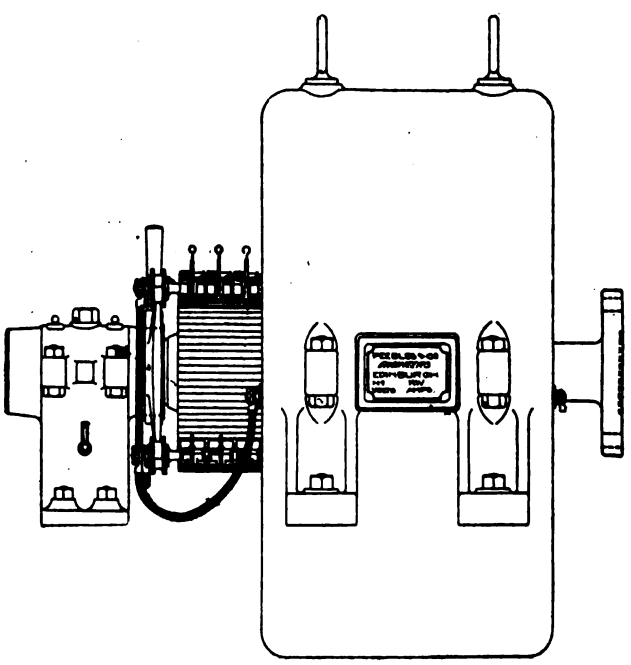

FIG. 2.—Traction Type Generator, Southport Tramways.

Digitized by Google

took up rather less than one-third floor space of the slow-speed plant with half the output. Three sets will ultimately be installed.

The switchboard, a view and diagram of the connections of which are shown in Figs. 3 and 4 respectively, was supplied by Messrs. Dorman and Smith, Salford, Manchester. It consists of 11 panels, three of them being generator panels, four feeder panels, two negative panels, one works panel, and a Board of Trade panel. On each generator panel is an ammeter and a voltmeter, together with equalising positive and negative switches. Each feeder panel is provided with an ammeter, automatic circuit breaker, main switch, lightning arrester, choking coil, and a recording wattmeter, which registers the number of units used on its circuit. In addition to the meters on the feeder panels there is a wattmeter on one of the negative panels which registers the whole current generated by the dynamos. Counting from left to right, panels 1, 2, and 3 are for the generators, 4 and 5 the earth return panels, 6 the works panel, 7 the Board of Trade panel, and 8 to 11 the feeder panels. There was insufficient room to get the board in a straight line, so an angular form was adopted, as shown, the effect being pleasing. The circuit breakers are of the latest Dorman and Smith pattern, and the main switches on the feeders are two-way, so that the feeders may be boosted up when required.

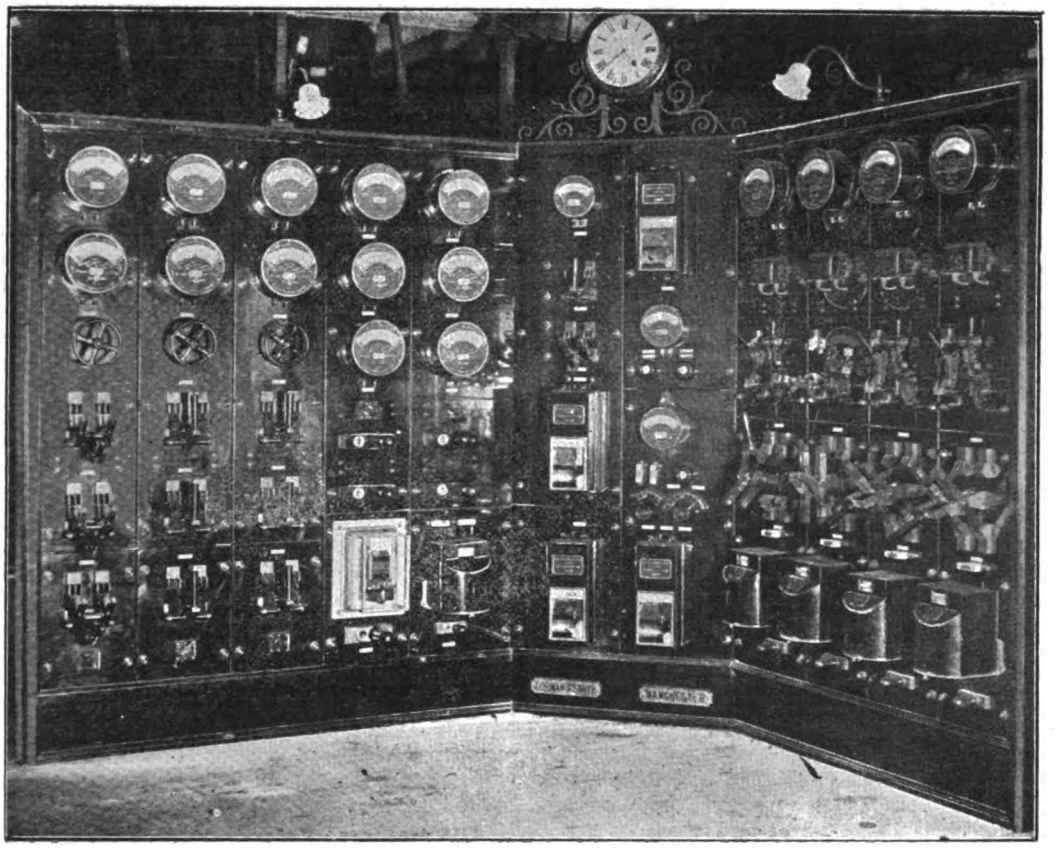

FIG. 3.—Traction Switchboard, Southport Tramways.

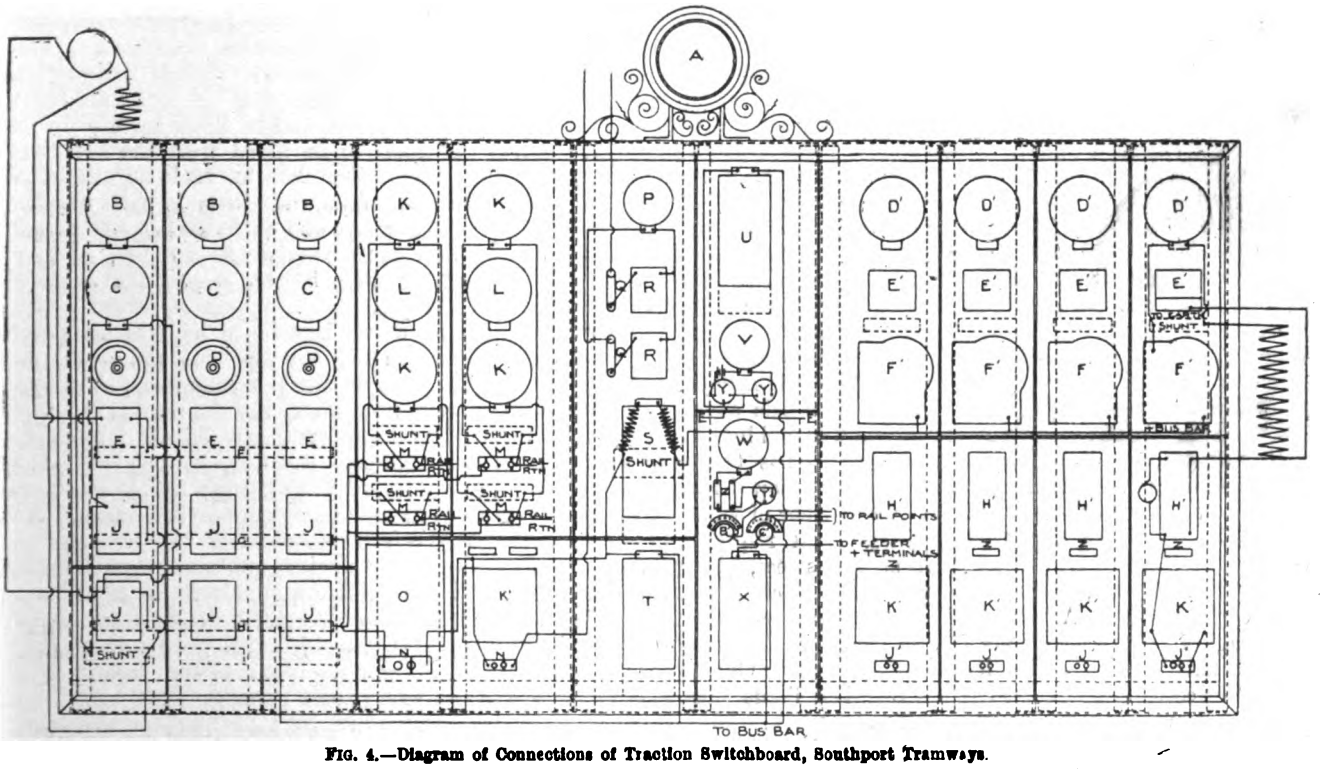

FIG. 4.—Diagram of Connections of Traction Switchboard, Southport Tramways.

Now we come to the outside work, and a few notes may be given concerning the permanent way. This portion of

Digitized by Google

the work, like the other sections, has been executed in a most thorough manner, and great praise is due to the Corporation staff, with the borough surveyor (Mr. R. P. Hirst) at its head, for the excellent manner in which the foundations for the track, which is probably equal in every way to any in the country, has been laid. All the concreting, paving, and excavating has been done by the Corporation's own men. The rails and accessories were, however, furnished by Messrs. Dick, Kerr, and Co., Limited, and some 800 tons of steel girder rails of their No. 75 section have been employed. These rails weigh 87lb. to the yard, are made up in 40ft. lengths, and nearly 1,600 pairs of this firm's well-known "Dicker" patent joint were used in the construction of the line. The gauge is the standard 4ft. 8½in.

Overhead Construction.—The contract for the overhead construction was placed with Messrs. Macartney, McElroy, and Co., Limited, of Westminster, on Dec. 11, 1899. As the contract was accepted on a strict premium and penalty basis, the contractors commenced operations in the early part of January, some time before the Corporation had commenced to lay the permanent way. The side bracket type of construction is employed throughout, the poles being 31ft. in height, and weighing approximately 1,200lb. each. The latter were designed specially by the company's engineers, and met with the approval of the Corporation. The trolley wire is 00 B. & S. gauge, and is double over the single track. The insulators are of the Macartney type, and designed by him several years ago for American use. With the exception of the Sussex-road section, the hangers are attached direct to the brackets; on the Sussex-road they are attached to a flexible arrangement, which is probably a superior method. The line is divided into half-mile sections, and fed from standard section pillars. The complete six miles of overhead equipment was practically completed within three months of signing the contract, which reflects great ability on the part of the contractors to execute work in quick time, since the material was designed, delivered, and erected in practically 90 working days. There have been, of course, a few changes due to the line of the permanent way, and especially its curves, not being exactly where they were anticipated by the overhead contractors, nor of the same radii. These changes, however, did not prevent the successful operation of the trams well within the stipulated time for completion.

During the inspection of the lines last week we noticed what appeared an unusually large number of anchor wires, but have since found that these were put up in compliance with the wish of the Corporation to have their trolley wire hauled up tight for the opening ceremony, which took place in the hottest weather. These anchor wires will serve to prevent breakage of the line when cooler weather and consequent contraction of the wire succeeds.

Cable Work.—A short description of the cable work may now be given. The whole of the feeder and rail return cables, together with the Board of Trade pilot cables, have been manufactured and laid by Callender's Cable and Construction Company, Limited. The feeders consist of ·4 square inch vulcanised-bitumen cables, laid in earthenware conduits and run in solid with pure Trinidad bitumen, the whole main being protected with a hard tile cover. The feeder leaves the generating station, and is laid by way of Peel-street, Sussex-road, and Ash-street to the feeder pillar near the rail-head in that street. It is looped into and out of three section pillars *en route*, either of which pillars can be used for feeding purposes if required. A subsidiary feeder is continued from Ash-street, along Scarisbrick New-road, which will eventually be carried as far as Chapel-street. A lead-sheathed and armoured cable, consisting of three cores each $^{7}/_{23}$, is laid direct in the ground alongside the entire length of feeders. One of these three-cores is to be used as the Board of Trade wire, and the other two for telephonic communication. They are also introduced into every section pillar, where suitable terminals are provided. The rail returns are laid solid, similar in all respects to the feeders, but consist of two cables each ·75 square inch. They follow the same route as the feeders till the corner of Tithebarn-road and Sussex-road, whence they are continued by themselves to the rails at the junction of St. Luke's-road and Sussex-road. A single-core $^{7}/_{22}$ lead-sheathed and armoured pilot cable is laid alongside the two rail returns the whole length of their route. The return cables are bonded on to the rails with flexible copper bonds, which are tee'd off the vulcanised-bitumen cable. The earthenware conduits for the feeders and the whole of the tile coverings were supplied to Messrs. Callender by the Stonite Patent Conduit Company, of Liverpool, the troughs for the rail returns being made by Messrs. Doulton and Co. The Stonite conduits are provided with a self-interlocking socket joint, which prevents any vertical and horizontal displacement of any conduit with reference to its fellow or adjacent conduit. In the event of ground subsiding beneath these self-locking joints, no strain is thrown on the cable contained therein. The whole of this cable work has been carried out under the supervision of Mr. F. A Pocklington, who has been laying cables for Messrs. Callender for 12 years in the North-Western district.

Rolling-Stock.—The rolling-stock for the present consists of nine double-decked cars, but there are also six single-decked cars on order. Messrs. Dick, Kerr, and Co., Limited, were the contractors for both these types of car. The cars now running were manufactured for them at the Electric Railway and Tramway Carriage Works at Preston, and are of the reversed stairway type, which, while affording complete protection to the passengers from the danger of falling when ascending and descending the stairways, also allows an increased seating capacity of something like 12 per cent. The cars are well designed, of handsome appearance, and thoroughly well constructed throughout. They are mounted on Brill 21 E. trucks, and are lighted electrically, having eight lamps in the interior, and also headlights and platform lamps. The electrical equipments were designed by Prof. Short, and are of the same type as those supplied by the contractors to Liverpool, Bolton, Dover, Sunderland, and other corporations. Two standard type motors, each having a capacity of 25 h.p., are fitted to each car, the controllers being of the solenoid blow-out pattern. Each car carries 22 passengers inside and 34 outside. The six single-deck cars on order are combination open and enclosed cars, seating 16 passengers inside and 16 outside. The electrical equipments of these cars are entirely of British manufacture (like the cars themselves), having been constructed at the works of the English Manufacturing Company Limited, at Preston, which were opened last month, and a description of which has already appeared in these pages, as our readers will doubtless remember. These new works are situate opposite the Electric Railway and Tramway Carriage Works, where the car bodies are made and consequently these car bodies have merely to be shipped across the road to be fitted with the necessary equipments. Final tests can then be made on the actual spot of manufacture, and small disparities in parts rectified without involving the delays and expenses inevitable when the car factory and equipment works are not, as here, practically on the same site. In this respect the works in question are quite unique.

Car Depôt.—A few words remain to be said about the car depôt, which is situated not far from the generating station buildings. Though not yet completed, the depôt was in a sufficiently advanced stage at the time of our visit to judge of its ultimate appearance. This will be exceptionally fine and a credit to the Corporation's able staff, who are here again concerned, the designs for the buildings having been got out in the borough surveyor's offices. The style may be termed a free treatment of the Renaissance. The front elevation shows a centre gable with a smaller one on either side, and is built of Accrington brick, the ornamentations being of dressed stone. The side walls are also of brick, but the back is of wood, the object being to enable extension to be more readily made. The roof is of iron in three bays, and is covered with patent glazing. The interior of the building measures 122ft. by 150ft., and of this space some two-thirds is available for the accommodation of cars. The remaining third is fitted for painting and repairing work and offices. The interior is well finished, being lined with brick, with a dado of salt glazing. The cost of the building is estimated at about £6,000, exclusive of foundations. The cars will enter through three doors, and each

Digitized by Google

rail inside has a cleaning pit of about 50ft. in length. Accommodation will be afforded for 32 cars.

The borough electrical engineer, Mr. Charles D. Taite, has been responsible for the electrical equipment of the new lines throughout, no assistance having been called in from outside. Mr. Taite has also large extensions to the lighting section of the electricity works on hand. The capacity of the plant already installed, including the traction generators, amounts to about 3,000 h.p., and the new extensions provide accommodation for a further 6,000 h.p., making 9,000 h.p. in all. A very fine and commodious new engine-room, opening into the older room, has already been erected. Electric lighting is making rapid headway in Southport, as the above figures would suggest. Several important additions to the lighting plant have been made since the station started supply, the most recent of these being a 600-kw. Ferranti copper-type alternator, which was installed less than a year since. When the extensions now in progress are complete, Southport will have a very fine station indeed. In conclusion, we have to express our thanks to the several contractors concerned for most of the information given above.

THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

EIGHTH ANNUAL MEETING AT KIEL.

[BY OUR OWN CORRESPONDENT.]

(Continued from page 87.)

The electrical plant in the Government dockyard at Kiel is much more scattered, consisting virtually of a number of independent installations of varying capacity. The first of these installations was put down in the early eighties, since when numerous additions have been made, but according to no systematic plan. Hence a number of independent plants have been put down, each designed to serve the requirements of a limited area of distribution in its immediate proximity. All the generators are of the continuous-current type, their distribution between the several departments of the establishment being as follows:

Shipbuilding yard proper	100 h.p.	—2 × 120 volts
Engine-building shops	500 ,,	—2 × 120 ,,
Carpenters' shop	30 ,,	65 ,,
Smithy	16 ,,	65 ,,
Foundry	40 ,,	65 ,,
Torpedo factory	20 ,,	110 ,,
Torpedo-mounting shop	15 ,,	65 ,,
Torpedo-repairing shop	30 ,,	110 ,,
Seven series-wound machines for general lighting purposes, each of 10 h.p. (on three sites)	70 ,,	550 ,,
Total	821 h.p.	

Of the several machines enumerated above, the latter seven each supply current to a separate circuit of from eight to ten arc lamps, arranged in series and serving for the general lighting of the yard. All of the 110 and 65 volt generators serve small individual areas of consumption.

On the other hand, the 100-h.p. and 500-h.p. machines constitute a combined direct-current plant, which feeds into an extensive three-wire distributing network of mains. The machines are situated about 1,310ft. apart, but may be paralleled together from either station. The 100-h.p. set consists of two separate compound-wound dynamos coupled direct to a compound steam-engine, while the 500-h.p. set consists of two compound wound generating machines, coupled direct to a marine type triple-expansion engine taken out of an old torpedo boat.

Amongst other purposes, electricity is employed in the dockyard for lighting the wharves, workshops, offices, and ships under construction and repair, transmitting power to motors driving countershafting, cranes, lifts, pumps, large and small machine tools, and portable drills employed during the construction and repair of ships, electro-plating, charging accumulators, and tests. Throughout the dockyard there are about 2,550 16-c.p. incandescent lamps at present installed; 360 arc lamps, consuming eight amperes each; 82 motors, aggregating about 500 h.p.; one continuous-current transformer, two stationary batteries of accumulators, and one accumulator boat. As in the Germania (Krupp) Werft, already described, the use of electricity is also to be largely extended in the Government dockyard, and especially in connection with the large new docks in course of construction. The two main pumps, it may be mentioned, representing about 875 h.p., are to be driven by electric motors, besides the apparatus for moving and pumping out the pontoons. The new power-house, which has already been erected, is to be equipped with a multiphase plant to generate current at a pressure of 1,000 volts for transmission to the various centres of consumption. No reduction of pressure, other than that represented by the loss in the leads, is to be made to the large motors, which will be wound for the full initial pressure of 1,000 volts. For the small motors and any others that may be situated in a damp position, the current will be transformed down to 110 volts, while the lighting circuits will also be supplied at the lower voltage. Plant having an aggregate capacity of 1,000 h.p. is to constitute the first instalment, but it is intended to gradually concentrate the whole of the generating plant serving the requirements of the dockyard on the one site. So far as can be at present foreseen, a total of about 3,000 h.p. will be required to meet the maximum demand. A combined multiphase direct-current system with motor transformers is to be adopted, since direct currents cannot be dispensed with for certain purposes. It is estimated that the rearrangement of plant entailed by the extensions will be completed by 1905.

There are other works installations, etc., in Kiel too numerous to mention in detail, but illustrating incidentally the extensive and varied application of electricity to industrial purposes in Germany. At the works of the Baltische Electricitäts Aktien-Gesellschaft, for example, electricity provides the exclusive power employed, some of the machines being driven separately by its means, while others are grouped. Of the electrically-worked tramways in Kiel little need be said; they are company-owned, and were opened for traffic in 1896. There are at present three lines in operation, having a total length of 12¾ miles single track. The heaviest gradient is 1 in 15. The motorcars are of a small single-deck type, and 41 in number. Each is equipped with two motors. There are no features in regard to the power-house which call for particular mention beyond that its equipment comprises three vertical compound engines, capable of each developing a maximum effective output of 200 h.p. To these are coupled in pairs six traction-type generators capable of having an aggregate output of 410 kw. at 500 volts terminal potential. The lines are equipped on the overhead trolley system. A five minutes' service of cars is in operation over the whole system, the receiver-box method of payment, without conductors, being employed, with a uniform fare of 10 pfennige—the equivalent of about 1½d. Tickets are also issued in bulk at reduced prices. In 1899 1,040,000 car miles were run, and about 4,000,000 paying passengers carried. There are five stations at which passengers may change from one line to another without extra payment. Further lines are are in course of construction, which are destined to provide a means of communication between Kiel and the township lying on the opposite side of the harbour. This extension will have a length of 6 miles, and a separate generating plant will be put down to work it, consisting of two dynamos of an aggregate capacity of 440 kw., with a terminal potential of 550, coupled direct to as many compound engines capable of each developing a maximum effective output of 330 h.p. There will also be installed a buffer battery of 270 elements and 198 ampere-hours capacity. As in the case of the already existing power station, steam will be supplied to the engines by water-tube boilers. These will be two in number, each having a heating surface of 2,280 square feet.

So much for the actual and prospective electrical attractions of Kiel. I may now return to the proceedings of the Verband, in which connection it must not be forgotten to mention that Herr Hartmann, of the well-known firm of Hartmann and Braun, Frankfort-on-Maine, was elected president in succession to Herr von Siemens, whose term of office had just expired. It transpired during the further business of the meeting that an under-

Digitized by Google

standing was in sight between the Government and the Verband relative to the periodical inspection of electrical installations, and that an association having for its aim the promotion of this important question in Berlin was in course of formation. Several new commissions, besides those already mentioned, were appointed, amongst other things, to consider in what direction, if any, an improvement could be effected in the existing patent laws, and to test and specify the insulation of wires and cables.

I have already referred to several papers read at the meeting, but there were various others of an interesting nature contributed, brief reference to which may be made. Dr. Hans Goldschmidt, of Essen, dealt in a highly-appreciated paper with the question of rail-welding by the process of obtaining high temperatures with the aid of aluminium. The discovery made by the author in this direction will be fresh in the minds of the reader. It attracted considerable attention at the time, and has since been turned to practical account with considerable success. Dr. Goldschmidt, in his introductory remarks, briefly described the process. While hitherto temperatures of 3,000deg. Celsius have been attainable only with the aid of the electric current and the bulky apparatus thereby involved, Dr. Goldschmidt has discovered a mixture of aluminium and oxygen termed "Korund," which developes this temperature upon simple ignition, thereby enabling thick steel plates and massive iron bars to be bored through in a few minutes. The process also serves to reduce metals to a fluid state which are otherwise difficult to melt, such as chromium, manganese, titanium, etc., all of which obtain extensive employment in the steel and copper industries. But, in addition to this phase of utility, Dr. Goldschmidt has adapted his discovery for welding purposes, the practical outcome of which is to be seen in Essen and Braunschweig, where long stretches of tramlines have already been welded together by the new process. Berlin, Hanover, and other towns have also decided to adopt the system. Dr. Goldschmidt made some practical demonstrations with the process before the meeting. He first of all showed its application to tube welding, for which purpose it is now employed in a large number of factories, one great advantage being that the work may be executed on the spot, besides being cheaper than the ordinary process. In executing the experiment, an assistant placed some of the Korund mixture in a crucible and thereupon ignited it, subsequently adding metal with a spoon. An interesting point in connection with the process is that the calories generated may be exactly predetermined. During the course of the demonstration the assistant had his eyes protected by smoked glasses from the intensely brilliant light developed by the melting process. After a very short time the glowing mass was ready for pouring into the mould, which held the ends of the tubes to be welded together in a horizontal position. The operation was accomplished by hand, for, in spite of the tremendous generation of heat, the crucible remained cold outwardly. Melting of the iron pipes is prevented by a protecting film formed by the Korund upon the surface of the same. Thin iron plates also remain unaffected in this way for the same reason. Two vertically-arranged pipes were next dealt with, and finally the method of welding rails by the new process was shown. Air is not admitted to the joint during the welding process, care being taken to exclude all oxygen. By this means the weld is rendered of excellent quality. It would certainly appear from what was shown that the process has a future before it. The advantages pertaining to a good system of welding rails are obvious. In the first place, the unevenness of the track at rail joints is avoided, whereby more even wear is ensured, and, secondly, trouble through vagabond currents is practically overcome.

THE PARIS EXHIBITION.

[BY OUR OWN CORRESPONDENT.]

(*Continued from page 59.*)

Another English exhibit which was not in working order at the time of my visit was the dynamo of the well-known firm of Mather and Platt, Limited, of Manchester. This machine is coupled to an engine made by Messrs. Galloway. The general arrangement of the combined set can be seen from Fig. 1. The dynamo is one of Mather and Platt's standard multipolar machines, designed for use on lighting or power circuits. It is of substantial design, and all details with regard to accessibility and compactness have been carefully considered. The machine is shunt-wound, and has an output of 220 to 250 volts and 1,400 amperes at 105 revolutions per minute. It is, however, capable of carrying a temporary overload up to 1,600 amperes, and is arranged to run in parallel with other generators in the Exhibition. It is of the 12-pole type, the yoke ring

Digitized by Google

and magnet cores are of cast steel, and arrangements are made so that the lower half of the ring can be lowered into the foundations, enabling any magnet winding to be taken off or to be easily inspected if necessary. The armature is central hung, being mounted upon the crank-shaft between the two bearings. It is not keyed to the shaft, but bolted direct to the heavy flywheel with which the engine is provided; this method of attachment ensures all flywheel effect being transmitted direct to the armature, no keys are subjected to an unnecessary strain, and a very stiff job is ensured. The armature is of the slotted type, the bars being laid in insulating tubes, and entirely embedded in the iron of the core, which is the usual practice in generators of this type, and efficiently protects the windings from damage. Special attention has been paid to the question of efficient ventilation both of the armature and the commutator, and the machine can consequently carry on the full load for long periods with but a small rise in temperature. The commutator is of large diameter and width, and of a design and construction up to the highest standard of modern practice. The current is collected by carbon brushes mounted in special holders, which admit of the contact pressure being adjusted as may be required, and each holder is fitted with "hold off" attachment. The efficiency of the generator is approximately 94 per cent., which with an engine efficiency of 91 per cent. gives a combined efficiency of 85·5 per cent. The engine, which is of the compound inverted type, is by Galloways, Limited, and is capable of developing up to 680 i.h.p. with high economy when provided with steam at 140lb., and going at 105 revolutions per minute. The high-pressure cylinder is 18in. diameter and the low-pressure 34in., both being arranged for a stroke of 3ft.; the cylinders are erected on standards of an enclosed type, the flywheel and dynamo being between. The distribution of steam to both high and low pressure cylinders is effected by Corliss valves having separate chests for steam and exhaust, both sets of valves deriving their motion from eccentric fitted on crankshafts driven from the end of the main crank pins. The whole of the valve gear is arranged on the outer sides of standards, and thus, owing to its accessibility, admits of ready adjustment at any time from the outside of the engine, and further, in conjunction with the enclosed design of the standards, avoids the risk of any oil, steam, or water being splashed upon the dynamo. The governor, which is of the high-speed centre-weight type, is positively driven from the valve shaft, and it automatically controls the expansion of steam in the high-pressure cylinder. Provision is also made for the adjustment of speed by hand while the engine is running. A neat and substantial platform is erected for access to the whole of the cylinder parts, valves, etc., and this is designed so as to give light to and convenience for lifting the dynamo parts. A system of forced lubrication is adopted, and the steam is superheated between high and low pressure cylinders. As is now generally the case in central-station installations, the condenser, which is of the ejector type, is fitted with an independently-driven water-pump. The engine throughout is of massive and substantial construction, and gives the French engineers a good idea of engineering work as done by our best firms.

The Exhibit of Messrs. Kolben and Co., of Prague.—To give the above firm its full name I should have called it the Elektricitäts Actien-Gesellschaft, vormals Kolben und Co. The personal interest that I feel for this firm is due to a friendship with its originator, Mr. Emile Kolben, and to an appreciation of the good work in electrical design which Mr. Kolben did both in America and Germany for prominent firms of electrical engineers before he commenced business on his own account in Austria. The works of the firm are particularly interesting from the fact that they are laid out for the construction of alternators of large size. In order that this may be conveniently done, Mr. Kolben has not laid down large tools to handle the large castings, which are inevitable with these multipolar machines and alternators. Instead of them, he provides a number of portable tools, which can be conveniently moved round the work. The result is that a great saving is effected both in first cost of equipping the works and, what is more important, in the speed with which such work can be put through the shops. An illustration of these tools is to be seen in Fig. 2, in which they are operating on the star wheel of one of the large alternators in the course of machining. Fig. 3 is a view in the same workshop to show how the cores of this Paris machine were built up and wound with wire. I understand that the first large electrical generating unit which was able to supply power to the exhibition was this three-phase steam alternator of Messrs. Kolben and Co. It was started at May 2, and both engine and dynamo were so well tested beforehand in the factory, and so well fitted in place, that at the very day of starting it was able to furnish current for the lighting of "Vieux Paris." The plant in question is situated in the Belgian section of the gallery devoted to the electric service of the Exhibition. It is placed at the foot of the large staircase coming down from the "Palais de l'Electricité" into the "Galerie des Machines." It consists of horizontal tandem compound steam-engine making 94 revolutions per minute, of the firm Carels frères, of Ghent, driving the flywheel-type three-phase alternator. This alternator is designed to give 1,100 effective

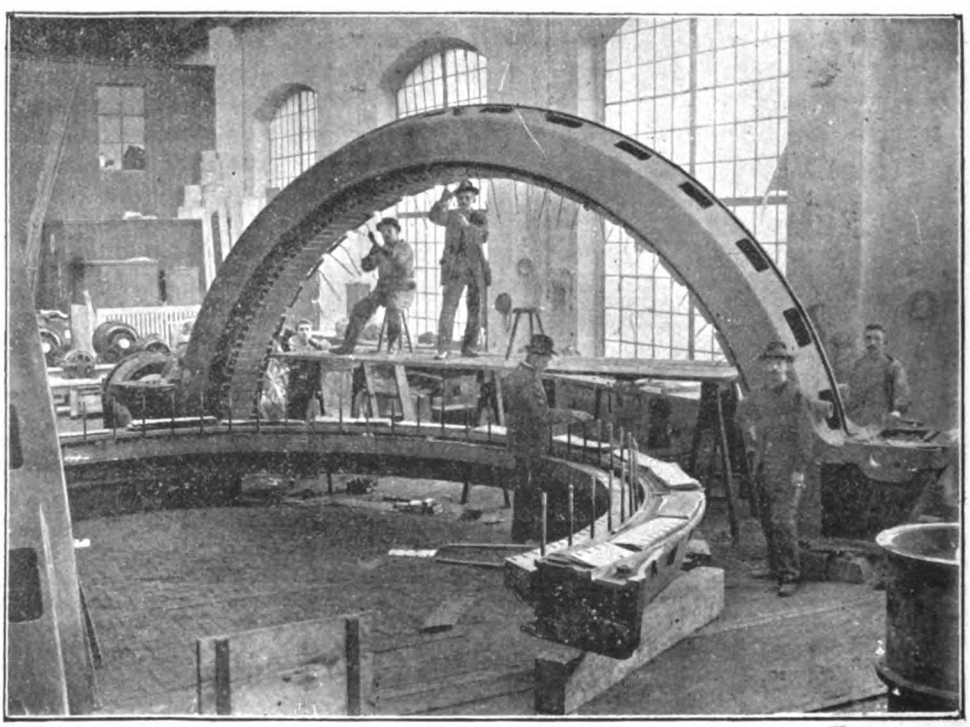

FIG. 3.—Building up and Winding the Armature Core of the Kolben Alternator.

Digitized by Google

horse-power for driving induction motors, furnishing 825 kw. at a compound pressure of 3,000 volts. The magnet wheel has 64 poles, thus generating at 94 revolutions per minute a periodicity of $64/2 \times 94/60 = 50$ cycles per second. The magnet wheel is made in two halves, and consists of a heavy cast-iron flywheel carried by 10 double arms, in the rim of which are fitted the magnet poles of cast steel. The rim has a weight sufficient to reduce the irregularity of the angular velocity to 1/200, having an inertia of $G D^2 = 600{,}000$ square metre-kilos, where G is the weight in kilos and D the average diameter in metres of the flying masses. The 64 magnet steel cores have an oval cross-section, and have cylindrical projections which fit exactly in corresponding holes in the flywheel rim, thus

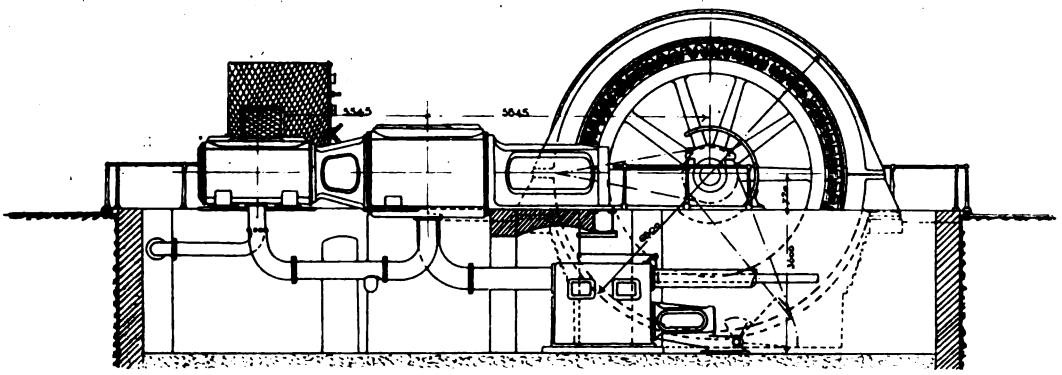

FIG. 4.—Side Elevation of the Kolben Alternator and Engine.

reducing the magnetic reluctance between steel and cast iron in correspondence with the different magnetic properties of steel and cast iron. The poles of the cores are made of iron laminations, which are cast into the steel cores. The core winding is made of copper band of 5mm. by 25mm., wound on edge. The adjacent layers are insulated from each other by means of parchment paper punchings. The magnet windings thus formed are hydraulically pressed together. The rim velocity of the wheel is 5,400ft. per minute, the external diameter of the wheel being 18ft. 3in. The stator which carries the high-pressure winding has a laminated iron core with deep slots, which are insulated by micanite troughs. The high-pressure winding consists of 96 coils, which 96 coils are laid in the slots and solidly fastened therein. The whole is carried by a strong cast-iron frame,

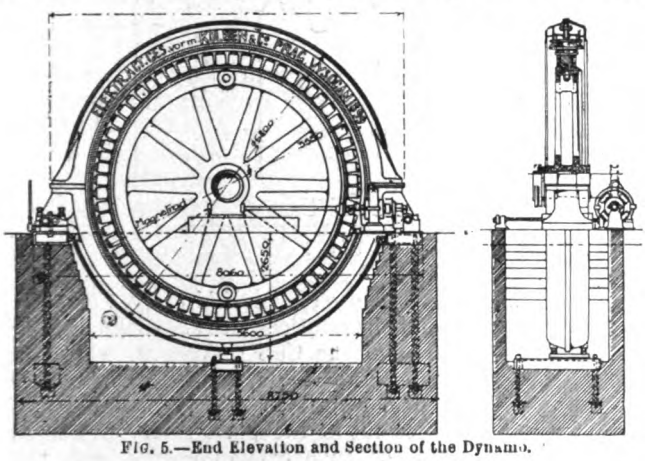

FIG. 5.—End Elevation and Section of the Dynamo.

which can be shifted axially, so that single armature coils as well as magnet coils can be easily replaced. The stator frame is also adjustable in the vertical direction by means of heavy adjusting bolts resting upon the cast-iron sole-plates. The magnetic proportions of the alternator, as well as the windings, are so calculated that at varying loads only very small pressure variations are noticeable. The dynamo is therefore designed with a high air-gap induction, strong iron saturations, small armature leakage and reactance, having a good pressure characteristic at no load, and a favourable short-circuit curve. The full-load current is reached with the short-circuited armature windings at an excitation corresponding to one-third of the normal voltage. The dynamo works at full and even at 25 per cent. overload very quietly without humming. The total weight of the dynamo, excluding exciter, is 62 tons. A general idea of the alternator and engine can be obtained from Figs. 4 and 5.

The exciter for the alternator is a six-pole continuous-current dynamo, whose armature is keyed directly on to the main engine shaft. It makes, therefore, only 94 revolutions per minute, and generates a current of 100 volts and 80 to 100 amperes. The whole energy required for the excitation is, therefore, about 1 per cent. only of the useful output. From the terminals of the alternator three high-pressure main cables are led to the distribution switch-board, which carries all controlling safety and measuring apparatus. The high-pressure switches of the board are so designed that their manipulation is perfectly without danger; they are handled by the machinist standing upon an elevated platform. The three-phase current generated by the Kolben three-phase alternator is used for feeding the high-pressure distribution network of the Exhibition. In the village "Old Paris" there are installed seven Kolben three-phase transformers, which transform the high pressure of 3,000 volts down to 110 volts, which is being used for lighting by arc and incandescent lamps. It may be remarked that the alternator exhibited by the Kolben Company carries the number "1,000," it being the one-thousandth dynamo manufactured by the firm. Five alternators of exactly the same size and output as the one exhibited are working at the three-phase central station of Prague, where they are used for generating current for the public and private lighting and power, and for the electric tramway service.

(To be continued.)

STANDARDS OF E.M.F.

BY JOHN HENDERSON, D.SC., F.R.S.E., A.I.E.E.

The practical unit of E.M.F., the volt, is legally defined as "that electrical pressure which if steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere," the ohm and the ampere being carefully defined quite independently of any measurement of electrical pressure. For practical purposes, however, the above definition does not supply a very ready means of reproducing the standard of E.M.F., assuming, as it does, the possession of a standard ohm and the means of measuring current in terms of the legal definition—viz., by means of a silver voltameter. The accurate manipulation of this latter apparatus involves much practice and a considerable expenditure of time, so that comparatively few measurements could be made in a day, and rapid measurements would be out of the question.

Recognising this fact, a supplementary definition of the volt is given, in which it is stated to be a certain fraction of the E.M.F. (at a definite temperature) of a primary battery which has been constructed in a specified manner. If, then, the E.M.F. unit is to be expressed in terms of the potential difference of a primary battery, it is obvious that we should possess the fullest knowledge of the behaviour of that cell under varying conditions, and also that the cell should fulfil all the requirements of a standard of measurement.

Before we examine the behaviour of various cells that have been suggested as possible standards, and in particular of that form chosen in the definition of the volt, it will be as well

Digitized by Google

to specify the conditions to be fulfilled by any satisfactory standard; these are as follows: (1) the standard cell must be easily made and reproduced; (2) the E.M.F. of such a cell must remain constant under constant physical conditions; (3) the nature of the alteration of the E.M.F. of such a cell with altered physical conditions must be accurately known; (4) the E.M.F. must return to its original value when the original conditions are reproduced; (5) all impurities likely to occur in the materials of which the cell is composed should produce a negligible effect on the E.M.F.

In order to determine whether or not a cell fulfils these requirements, the following measurements must be made: (*a*) the measurement of the E.M.F. of the cell under known conditions; (*b*) the measurement of E.M.F. with various added impurities likely to occur in "commercial" samples of the materials of which the cell is composed; (*c*) the measurement of the variation of E.M.F. with temperature; (*d*) the behaviour of the cell when supplying a current, with special reference to the rate of recovery of the E.M.F. from the effects of polarisation.

In what follows it is proposed to consider the construction and behaviour of several of the more important cells that have been suggested from time to time for use as standards, and to see in how far they fulfil the above conditions and requirements.

The Standard Daniell Cell.—In all primary batteries the chief cause of variation of E.M.F. is due to polarisation, and the majority of cells that have been invented represent more or less satisfactory attempts to reduce or entirely remove this trouble. There are three principal methods of doing this: (1) the mechanical method, in which the polarising hydrogen is brushed or otherwise mechanically removed from the surface of the negative plate; (2) the chemical method, in which the hydrogen is removed by the aid of some oxidising substance—this method is employed in the majority of cells such as the Bunsen, Leclanché, Bichromate, etc.; and (3) the electro-chemical method as represented in the Daniell cell, in which the hydrogen of a sulphuric acid molecule is made to replace the copper in a copper sulphate molecule, and deposit the copper on the negative copper plate.

As far as regards its use as a standard of E.M.F., we need only consider one form of this cell—viz., that devised by Dr. Fleming, who has carefully investigated the best conditions under which the Daniell cell can be used, and the E.M.F. of the cell under varying conditions. The cell is set up in a glass U-tube, to the upper ends of the limbs of which are attached small glass reservoirs communicating with the U-tube through glass taps. The tube is filled with copper sulphate and zinc sulphate solutions, so that there is a sharp interface between the two near the level of the small escape tap fused into the U-tube near the bottom of one of the limbs, and by opening which and running out a little of the liquid the sharpness of the interface may be restored should it become blurred by gradual diffusion. The reservoirs contain stores of zinc sulphate and copper sulphate solutions respectively, which can be drawn upon as the level of the liquid in the U-tube falls. Into the side of the U-tube containing the copper sulphate solution is placed a rod of pure copper, whilst into the zinc sulphate solution is placed a rod of pure amalgamated zinc. The whole apparatus is mounted on a wooden stand (see Fig. 1), small glass side tubes being provided to hold the copper and zinc rods when the cell is not in use.

As regards the value of the E.M.F. of the cell, Dr. Fleming has shown that it depends to a large extent on the strength of the solutions and on the condition of the copper and zinc rods. The copper rod should be made from a thin copper wire 4in. long, on which copper is electrolytically deposited until it attains a thickness of ¼in., and whenever the cell is to be used after having stood idle for some time a fresh layer of copper should first be deposited on the rod. The zinc rod is of the same dimensions, and consists of double-distilled zinc carefully amalgamated with pure mercury. The solutions employed may be of two strengths: (*a*) equi-dense solutions of specific gravity, 1·2 at 15deg. C., or (*b*) $ZnSO_4$ solution of specific gravity 1·4, and $CuSO_4$ solution of specific gravity 1·1, both at 15deg. C. Of these, solutions (*a*) are made by dissolving 28·25 parts by weight of pure $CuSO_4$ in 71·75 parts of distilled water, and 32 parts by weight of $ZnSO_4$ in 68 parts of distilled water; whilst solutions (*b*) consist of 55·5 parts by weight of $ZnSO_4$ in 44·5 parts distilled water and 16·5 parts by weight $CuSO_4$ in 83·5 parts distilled water. Under the above conditions the E.M.F.'s of the cell are: with solutions (*a*) 1·102 volts; with solutions (*b*) 1·072 volts.

The effect of temperature on the E.M.F. may be neglected, since it only falls by ·00015 volt per degree centigrade rise of temperature. One of the most serious defects of this cell is that it is not portable, and thus can only be employed as a laboratory standard. The E.M.F. is found to rise by about ·003 volt after standing for some time, also the purity of the rods greatly affects the E.M.F. If the copper rod is sandpapered instead of being copper-plated, the E.M.F. is increased by 0·6 per cent., whilst oxidation of the copper rod raises the E.M.F. by variable amounts. Oxidation of the zinc rod, on the other hand, lowers the E.M.F., and the smallest deposit of copper on the zinc rod, such as is very liable to occur should any of the $CuSO_4$ solution find its way to the zinc, at once lowers the E.M.F. by 2 or 3 per cent. The strengths of the solutions also affect the E.M.F. An increase in density of the $CuSO_4$ raises it, whilst an increase in density of the $ZnSO_4$ lowers it. Another drawback to this particular form of cell is the liability of the $CuSO_4$ to crystallise out in the glass reservoir, and so choke up the tap in the tube communicating with the U-tube.

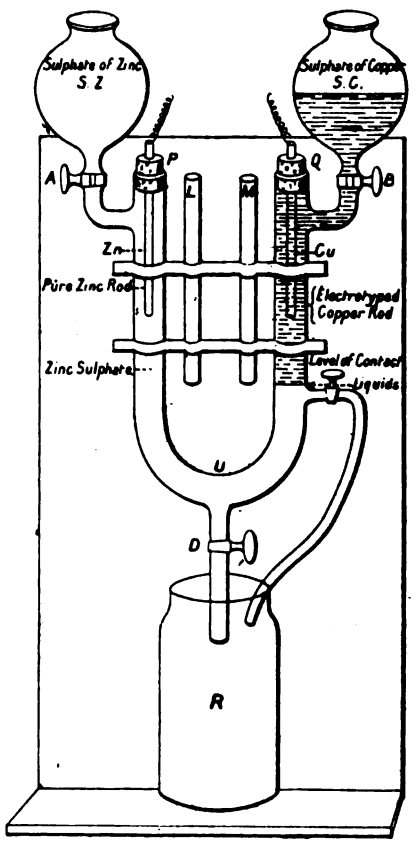

Fig. 1.

In cases where great accuracy is not required, an ordinary porous pot Daniell cell may be simply and rapidly made up with $CuSO_4$ solution saturated at 15deg. C. and acidified with sulphuric acid, the amalgamated zinc rod dipping into dilute sulphuric acid instead of zinc sulphate solution. The following table gives the results of measurements made by the author on such a cell, 15 minutes after having been made up.

Electrolyte round copper plate.	Electrolyte round zinc rod.	E.M.F. Volts.
100 c.c. $CuSO_4$ + 0·5 c.c. H_2SO_4	100 c.c. H_2O + 0·5 c.c. H_2SO_4	1·142

Digitized by Google

The H_2SO_4 was ordinary strong sulphuric acid, and the H_2O tap water. If the above voltages are plotted out against the volume of H_2SO_4, it will be seen that the best conditions obtain between 10 cubic centimetres and 20 cubic centimetres of H_2SO_4 to 100 cubic centimetres H_2O, as the E.M.F. changes least rapidly then with a given change in the amount of the acid added. The Daniell cell, on account of the trouble in preparing it, and from its not being portable, is not much used now as a standard of E.M.F.

The Clark Cell.—The most important of all the primary cells in use at the present time for standard purposes is undoubtedly one or other modification of the cell originally proposed by Mr. Latimer Clark. This is partly due to the large amount of accurate information possessed regarding its behaviour, and partly to the fact of its having been chosen by the Board of Trade as their standard cell. The particular form of this cell, mentioned in their specification, is known usually as the Board of Trade or B.O.T. Clark cell, and differs somewhat from the original form. As, however, there are a great many modifications of this cell, and more especially as some of the most accurate information we have on Clark cells was obtained from some of these other forms, it will be necessary to describe some of the more important modifications, and to discuss their relative merits and deficiencies.

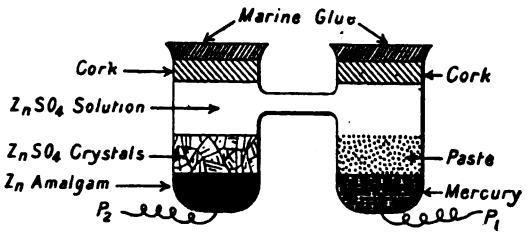

FIG. 2.

The Rayleigh H-Type of Clark Cell.—This modification was adopted by Lord Rayleigh after long and careful investigation. It consists of an H-shaped glass vessel (see Fig. 2). In one limb is placed some mercury which has been purified by distilling *in vacuo*, and to which contact is made by means of the platinum wire, P_1, fused through the glass. On the top of the mercury is placed a layer of paste composed of mercury, mercurous sulphate (Hg_2SO_4), and zinc sulphate ($ZnSO_4$). In the other limb is placed zinc amalgam (1 Zn to 9 Hg), a platinum wire, P_2, fused through the glass making contact with it. A few crystals of $ZnSO_4$ are placed on the top of the amalgam, and the remainder of the glass vessel is filled up with a solution of zinc sulphate saturated at 30deg. C. The open ends of the vessel are closed with corks and marine glue. Slight modifications on the Rayleigh pattern of cell have been made by Kahle and Cooper, the form due to the latter being specially adapted for immersion in a water-bath.

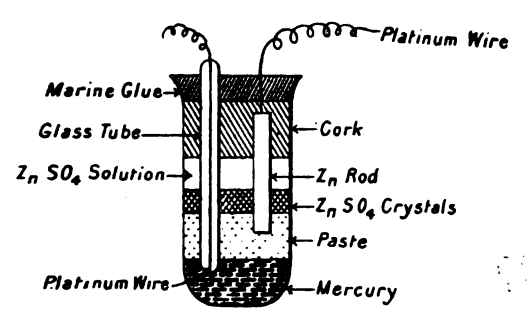

FIG. 3.

The Board of Trade Clark Cell—The shape and construction of the Board of Trade form of Clark cell is designed with a view to making the cell more portable than the Rayleigh form. The cell is made up in a glass tube (see Fig. 3). Pure redistilled mercury is placed at the bottom of the tube, contact being made to it by means of a platinum wire, the upper part of which is insulated from the rest of the cell by a glass tube. The paste above the mercury is similar in composition to that in the Rayleigh cell, the zinc sulphate solution also being saturated at 30deg. C. The negative electrode, however, consists of pure unamalgamated zinc, which passes through the solution and enters a little way into the paste. The cell is sealed up with a cork and marine glue. A few additional hints on fitting up these cells have been given by Mr. Glazebrook, who advises the addition of a little zinc carbonate to the $ZnSO_4$ solution to neutralise any free acid, and also the addition of $ZnSO_4$ solution to the mercurous sulphate paste, this latter being made up of Hg_2SO_4, "purchased as pure," and washed with distilled water, some pure mercury being added to the paste to "preserve the basicity of the salt, which is of the utmost importance." Also, in a cell made up in accordance with Glazebrook's suggestions, the zinc rod does not penetrate into the paste, although apparently there is nothing to prevent the paste coming in contact with the zinc should the cell be shaken. Clark cells of the Board of Trade pattern are stated to have an E.M.F. which will not vary more than 0·001 volt from 1·434 volts at 15deg. C.

The Carhart-Clark Cell.—This form was introduced by Prof. Carhart to overcome some of the objectionable features

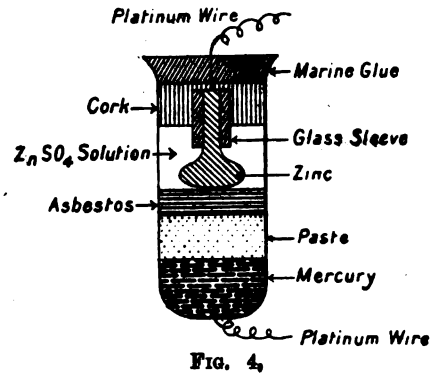

FIG. 4.

met with in the Board of Trade Clark cell. The arrangement of materials is shown in Fig. 4. The pure mercury at the bottom of the glass tube has contact made to it by the platinum wire fused through the glass. On the top of the mercury is a layer of paste, as in the Board of Trade cell, but separating the paste from the zinc rod is a layer of asbestos, which prevents the paste coming into contact with the zinc. The zinc rod is flattened out at the lower end to increase its active surface, whilst the upper part of the rod is protected by a glass sleeve. Contact is made to the zinc by a platinum wire in the usual manner. The zinc sulphate solution in the cell is saturated at 0deg. C. instead of at 30deg. C., as in the Board of Trade cell, and in consequence of this the E.M.F. is about 0·4 per cent. higher, being 1·438 volts at 15deg. C.

Callendar's Crystal Clark Cell.—This is a modification of the Board of Trade cell introduced by Prof. Callendar, in which the zinc sulphate solution is replaced by moist crystals of $ZnSO_4$ packed closely round the zinc rod. The glass containing tube is smaller in bore and considerably longer than in the Board of Trade form, thus admitting of the complete immersion of the active parts of the cell in a water-bath, and the more rapid attainment by the cell of the temperature of the water-bath than is possible in cells having a larger thermal capacity. There are various other modifications of Clark cells of more or less importance, the modifications mostly being in the structural arrangements of the cells. Of these we can only mention one—Muirhead's form of Clark cell, in which an amalgamated platinum spiral (formed by plunging red-hot platinum into mercury) replaces the mercury in the ordinary form, the advantage claimed being greater portability.

Defects of Clark Cells.—One of the chief criticisms levelled against Clark cells in general, and the Board of Trade form in particular, during recent years refers to the inconstancy of the E.M.F. This may be experienced in two ways: (*a*) cells made up by different people with chemicals emanating from different sources are found to differ in their E.M.F.'s; and (*b*) cells made up by the same individual, which agree amongst themselves when new, are found to differ, in some cases very considerably, after

Digitized by Google

having been in use for some time. That the first want of agreement should exist is not very surprising, and points to the presence of impurities in the materials of which the cells are composed, the words "chemically pure" being capable of very wide interpretation. This cause of difference, nevertheless, is a very serious one, since not only is it impossible for all who wish to construct standard cells to obtain their chemicals from the same source, but there is no real assurance that the same standard of purity will be maintained for any lengthened period by the same manufacturer; thus, for instance, various manufacturers will supply, say, Hg_2SO_4, which they describe as being "chemically pure," and which may be so in so far that no other metal than mercury is present, yet the various samples will differ enormously in acidity; one sample may give no acid reaction, whilst another is strongly acid. This difference in acidity of the materials may in many cases account for the peculiar behaviour of the cells which are made up from them. The causes of the irregularities of E.M.F. in the second case are, if anything, still more serious on account of the difficulty of localising and removing them. In particular, it has been found that specimens of the Board of Trade cell cannot be relied upon to agree amongt themselves more closely than one part in 1,000 when freshly made up, and that after standing some time, even this agreement was not maintained, Cooper having found that cells which a week after construction had a mean error of 1 in 7,000, after 3½ years differed by 1 in 700, which is considerably more than the limit permitted in the Board of Trade specification. One of the causes of inconstancy in the Board of Trade cell which has been pointed out by Carhart is that the mercury is apt to come into contact with the zinc rod, which is not amalgamated, and thus alter the E.M.F. Local action may also occur where the zinc enters the paste, resulting in the amalgamation of the zinc. Another defect is that in consequence of the zinc sulphate solution being saturated at 30deg. C., ordinary fluctuations of temperature produce crystallisations and re-solutions of the $ZnSO_4$, thus setting up differences in density in the liquid at different levels, and in this way affecting the E.M.F. and favouring local action at the zinc rod. To overcome this latter difficulty Carhart introduced the Carhart-Clark cell, in which an asbestos plug separates the mercury salt from the zinc rod, whilst the $ZnSO_4$ solution is saturated at 0deg. C., so that at all ordinary temperatures there should be no $ZnSO_4$ crystals present in the cell, and consequently fluctuations in temperature will not cause differences in density in the solution. An objection to this modification has, however, been pointed out recently by Messrs. Spiers, Twyman, and Waters, who have shown that if an error of a few one-tenths of a degree be made in the temperature of saturation of the zinc sulphate solution, there will be a corresponding error of several parts in 10,000 in the value of the E.M.F. of the cell, and also that every time a current is taken from the cell a small quantity of zinc is dissolved, thus gradually increasing the strength of the $ZnSO_4$ solution. Another cause of variation in the Clark cell has been investigated by W. Jaeger. The normal $ZnSO_4$ crystal has the composition $ZnSO_4 + 7H_2O$; it, however, loses a molecule of water at 39deg.C., and becomes $ZnSO_4 + 6H_2O$. These two forms of $ZnSO_4$ possess different solubilities, and two cells made up each with a different form would have different E.M.F.'s. He also showed that if $ZnSO_4 + 6H_2O$ solution is allowed to cool slowly, it will not return to its original form, unless in contact with a crystal of the original form $ZnSO_4 + 7H_2O$. At 150deg. C. the difference in the E.M.F.'s of two such cells would amount to as much as 7 parts in 10,000, that cell made up from the $ZnSO_4 + 6H_2O$ crystals giving the lower E.M.F.

Temperature Coefficient.—In all forms of Clark cell the E.M.F. varies considerably with temperature, consequently not only is an accurate knowledge of the temperature coefficient necessary, but also an accurate knowledge of the temperature of the cell. The temperature in the ordinary forms of standard cell as supplied by instrument makers, is registered by a thermometer placed alongside the cell in the brass containing case. These thermometers are of two forms: a straight thermometer tube which projects up through the top case of the cell, and is, therefore, very liable to fracture; and the bent form, in which the tube is bent through 90deg. and lies along the top of the case cap. The great objection to this latter form is the tendency the mercury column has to break at the bend in the tube, and the great difficulty in getting it to join again. The position of the bulb inside the case is also open to criticism, since, on account of the difference in thermal capacity of cell and thermometer bulb, the former will not follow fluctuations of temperature anything like so rapidly as the latter, and there will always be uncertainty as to whether the thermometer really indicates the temperature of the cell or not, unless the cell has been kept at a constant temperature for at least half an hour before it is used. In the Rayleigh H-type of cell the temperature coefficient has been carefully measured by Lord Rayleigh for a number of different cells, and from the mean of the results the following correction for temperature has been obtained:

$$E_{t^\circ} = 1{\cdot}4345\ \{1 - {\cdot}00077\ (t^\circ - 15^\circ)\}.$$

Thus an error in reading the temperature amounting to 1deg. C. would correspond to an error ·08 per cent. in the E.M.F. In the Carhart-Clark cell the temperature coefficient is about one half of the above, the correction given by Prof. Carhart being

$$E_{t^\circ} = 1{\cdot}438\ \{1 - {\cdot}000387\ (t^\circ - 15)\},$$

the cause of the difference being the saturation of the zinc sulphate at 0deg. C. instead of 30deg. C. In the Board of Trade cell Ayrton states that, after having been set up for some time, the mercurous sulphate settles down, leaving a clear solution above, and should the zinc rod dip only into this clear solution and not into the paste, the temperature coefficient will be about half its normal value. Small alterations in the temperature of saturation of the $ZnSO_4$ solution also affect the temperature coefficient considerably. The Callendar crystal cell has a temperature coefficient practically the same as that of the Board of Trade cell.

(To be continued.)

GLOUCESTER ELECTRICITY WORKS.

On Thursday last week we attended, by invitation, the opening ceremony of the electricity works. The success of this opening was only marred by the great heat which was experienced on that day. The opening ceremony was held in the engine-room; the distinguished guests of the Electricity Committee and of Mr. Hammond took their position on the switch gallery. A number of speeches were then delivered, which we listened to until we heard Mr. Hammond descanting on the advantages from an architectural point of view of the temporary end of the engine-room. The temperature inside the engine-room inspired us with the desire to inspect the site for the extensions, and we finally found a cool corner on the top of the main flue. We learn from a local journal that the opening ceremony proceeded despite our absence. Thus after the Rev. Canon James had opened the proceedings with prayer, the chairman of the Electricity Supply Committee extended a hearty welcome to all those present. He proceeded to detail the history of the electric light undertaking, and called upon Mr. Hammond to give a description of the works. In this description Mr. Hammond explained his own capabilities of spending money, in which he was assisted by the inhabitants of Gloucester. The demand was so great that before the works were completed 15,000 lights had been applied for, and they had had to go before the Local Government Board for additional borrowing powers before all their first loan had been utilised. We gather that it is doubtful whether the extension of plant will not be actually running before the Local Government Board have "duly considered and granted" the application for additional capital. Mr. Clutterbuck then called on the Mayor to switch on the light, and, this having been done, the Mayor declared the works open. He expressed the hope that the electric lighting undertaking would be a great boon and blessing, being conferred on the whole of the

Digitized by Google

citizens. He trusted that the citizens would ever look upon the electric light as a mark of the progress and prosperity of the city of which they were all so proud. The opening proceedings concluded by a vote of thanks and tea, after which the visitors from London went into the crypt of the Gloucester Cathedral to get cool.

In the evening a banquet was held in the Guildhall, the host being Mr. Councillor Clutterbuck, the chairman of the Electricity Supply Committee; Mr. Robert Hammond, the consulting engineer; Mr. Harry A. Dancy, the architect; and the various contractors who supplied the plant, etc. A full toast list followed an excellent dinner, the Mayor, proposing success to the electricity undertaking, presented a gold watch to Mr. Clutterbuck as a token of the Council's appreciation of the valuable services rendered by that gentleman in his capacity as chairman of the Electrical Supply Committee. The Mayor also made the joke of the evening by suggesting that while Mr. Hammond had spent their money most economically, he did not think he had provided quite so many arc lamps as the guests would see on their way home that night. The electric lighting of the Guildhall, in which the banquet was held, was exceedingly brilliant, but the arrangement of the lights was not all that could be desired.

THE TELAUTOGRAPH.

We have this week seen, by invitation, at the offices of the British Telautograph Company the working of the above-mentioned instrument. We are, however, debarred at present by its inventor, Mr. Foster Ritchie, from publishing a technical description of the instrument, owing to the fact that patents for details have not yet been completed in certain countries abroad. The two illustrations we give herewith indicate in some way what results can be obtained by means of the instrument. Thus Fig. 1 is a record as written at the transmitting end, and Fig. 2 is the record received at the further end. Although we are not allowed to describe in detail the way in which the machine works, the following information will give a general idea of its principle. If an earth return is employed, two line wires are required between the sending and receiving station. The current in each of these line wires is varied by means of a rheostat, which is in series with the line wire and sending battery. The resistance of the rheostat is connected at frequent intervals to the small sections of a commutator in the form of a quadrant, and connection is made between this quadrant and the line wire by means of a fine brush. In connection with the pencil which is used to write the message to be transmitted are two connecting levers, which alter by a suitable mechanism the position of the two brushes bearing on the two quadrants or commutators. The levers which link up the pen to the brush gear are so devised that for any one position of the pencil of the paper, only one combination of positions of the two brushes on the two commutators is possible. In the receiving station the gear for recording is practically a duplicate of that for sending, except that the circular motion of the brushes on the commutator is reproduced by means of a moving needle of an enlarged D'Arsonval galvanometer. The position of one of the brushes on its commutator, of course, determines the current in the line wire connected with the same. Again, the angular position of the needle of the receiving galvanometer is determined by the current of the line wire, so that the linkwork on the receiving station exactly reproduces the motion of the linkwork connected to the pencil. At the point on the linkwork at the receiving station which corresponds to the pencil a recording pen is placed, which traces the message on the paper. It is very interesting to watch the movements of the pen when the operator, not used to sending on the machine, is considering what he will write. The success of these instruments is due to the perfection in detail. Thus the large-type D'Arsonval galvanometers used to move the recording pen are wonderfully dead-beat, and have little inertia in their moving parts considering the comparatively large force which they are capable of exerting.

The advantages of the telautograph are many, but the instrument is not intended in any way to replace the telegraph. It is rather a machine by which written instructions can be given to an agent at a distance, and for important communications involving an expenditure of money is decidedly to be preferred to the telephone. For instance, it renders it quite possible to prove the authenticity of the message from the fact that actual handwriting is reproduced, or, if need be, a clerk could be detailed to do the writing, and a member of the firm could sign the message as correct. Again, from the sender's point of view, a written record is kept of the instructions given, by which any tampering with the message afterwards could be prevented; also, all movements of the receiver being controlled by the sender of the message, it is not necessary that anyone be present at the receiving end, and if secrecy is required, the machine may be in a lock-fast cabinet. A list of the uses to which the machine could be put would be exceedingly tedious to our readers, but we are assured by the company that the orders already booked for the machines include a very wide range of commercial life. The company has secured a license from the Postmaster-General to use the machines on private lines erected by the Post Office or to be erected by that authority, but up to the present it has not the right to use the telautograph in connection with the exchange system of the National Telephone Company. We cannot up to the present obtain information as to the terms on which the instruments can be obtained, but we believe that at a very early date this will be forthcoming at the offices of the company, 97, Gresham-street, E.C.

BEHIND THE SCENES.

It is a little rough upon English business men to have it continually drummed into their ears that they do not know how to conduct business properly, that they must go to school again and learn from America, Belgium, Germany, and France how to do it. The fact is the speakers and writers who so harp upon our commercial position are of two kinds—first, those possessed of ignorance and credulity; second, those who have particular fads to run or fish to fry. The credulous folk accept the latest statement, whatever that may be, without a particle of doubt or any attempt to analyse in order to obtain the true conditions prevailing generally over the whole industry, their conclusions depending possibly upon those prevailing in one case alone. When, again, you hear a man condemning this, that, and the other, it is well to ask why. If he is an interested party, then enquire of the other side, and accept the truth as somewhere between the two extremes. Let us take a simple concrete example, interesting to many firms, and causing a wide divergence in tendering for this particular work. Because the amounts of tenders vary largely, surely till the matter is fully examined no one is justified in saying the heads of the various firms do not understand their business. The example we refer to is the capital cost of mains. So far as the cost of manufacture of cables is concerned, no doubt the various manufacturers know the cost of any particular cable to the fraction of a penny per yard; but what the contractors do not know, and what fluctuates almost beyond ordinary comprehension, is the cost of opening up and making good the paths and streets in the laying. According to our advices, the local authorities who usually "make good" and send in the bill to the contractors do not all act upon one system. In some cases, indeed, they expect and do make a profit. Now, the common-sense view of the question is that the local authority ought not to make a profit. They have to protect the interests of the ratepayers, and as the exigencies of installing the electric light include the breaking up of streets, it becomes their duty to see that the streets are left in quite as good a condition when the work is finished as they were before the work was commenced. No one who has not had experience in cable-laying can realise the varying cost per yard under the varying conditions, and the cost in the case of coterminous authorities when the conditions seem to be similar is often very different. It is hardly too much to say that the most experienced contractors for mains are compelled in their tenders to put down a sum for this purpose that is arrived at by rule of thumb. Sometimes they come out on the wrong side after making all allowances. Such, then, is this particular phase of business, and we contend that examination will often show that in other cases orders lost or gained are lost and gained by chance, and that the gain does not necessarily imply a profitable transaction, nor does it imply ignorance or inexperience on the part of those who are engaged in that particular industry or particular phase of an industry. We had

Digitized by Google

intended to discuss this question from one or two other standpoints, but perhaps we have said enough.

CORRESPONDENCE

"One man's word is no man's word,
Justice needs that both be heard."

THE RIVER TRIP.

SIR,—I have recently received from the Institution of Electrical Engineers a circular announcing the proposed arrangements for the entertainment of the members of the American Institute of Electrical Engineers who will be visiting this country during August.

It is with the deepest regret and concern that I note that the first item on the programme is a trip up the Thames on *Sunday*, Aug. 12! The hope is expressed that a large number of members and ladies will take part in the proceedings, in order that a "true British welcome" may be given to the guests!

Nominally, at any rate, this is a Christian country, and those who profess Christianity are supposed to at least adhere to the fundamentals of their religion. To keep the Sabbath Day is not only one of the most sacred obligations of Christianity, but it is quite foreign to all the traditions of this country for a public or a scientific society to give an entertainment upon that day.

Under the circumstances, therefore, it will scarcely be possible to give our American guests a "*true* British welcome." Fidelity to principle will, no doubt, keep many away, while probably some conscientious qualms may overtake a section of those who go.

I sincerely trust, however, that steps will be taken at once to remedy the matter, as, besides the foregoing reasons, it would be a deplorable precedent for the rest of the scientific societies, and it would undoubtedly cast a stigma upon the whole profession, in addition to bringing dishonour upon the country and involving our American *confrères* in the wrong-doing.—Yours, etc.,

A CHRISTIAN BRITON.

[While not wishing to start a discussion on religious subjects in our columns, we feel bound to give space to the letter above. The writer is a member of the Institution, and as such has the right to be heard on matters connected with the Institution with which he personally disagrees. As a number of the members will doubtless hold similar views respecting the keeping of the Sabbath, it is a great question whether the Council of the Institution of Electrical Engineers should not at least have made the Sunday excursion up the Thames a private function. At it is, they are offering our American guests hospitality in a way which is displeasing to a certain number of would-be hosts, and perhaps even some of the invited guests will abstain from the function for that reason. It is a matter on which the private opinions of every man are entitled to respect, and hence one in which unanimity is hardly to be obtained in any institution.—ED. *E. E.*]

THE POWER BILLS.

The consideration of the County of Durham, the Lancashire, and the Shannon Water and Electric Power Bills was entered upon on Wednesday by the committee of the House of Lords presided over by the Duke of Argyll. The Bills have already passed through all the stages in the House of Commons.

Mr. Balfour Browne, Q.C., Mr. Worsley-Taylor, Q.C., and Mr. Moon represented the promoters of the County of Durham Bill, which was taken first; and Mr. Fitzgerald, Q.C., and Mr. Lloyd appeared for the District Councils of Felling and Hebburn, who were the only opponents.

Mr. BALFOUR BROWNE explained to the committee the exhaustive character of the enquiry which had been held by Sir James Kitson's committee into the provisions of the Bills, and referred to the fact that the most important clauses which were introduced for the protection of the public and the local authorities were framed by the Government draftsman and put upon the several promoters by the House of Commons committee. He therefore asked their lordships to pass the Bill exactly as it left the other House.

Mr. FITZGERALD urged that the districts of Felling and Hebburn should be struck out of the proposed area of supply.

The DUKE OF ARGYLL, in announcing the decision of the committee, said they were of opinion that the Bill might proceed, with the exception of the clauses including Felling and Hebburn in the area of supply. Those clauses should be altered so that only wayleaves through those districts should be allowed. The Lancashire Electric Power Bill was then considered.

Mr. Worsley Taylor, Q.C., Mr. Pollock, Q.C., and Mr. Shaw appeared for the promoters of the Lancashire Bill. The opponents were the Corporations of Manchester, Liverpool, Bootle, Salford, Southport, and Bolton.

The learned counsel having explained the object and scope of the Bill, referred to the clauses which had been put upon the promoters for the protection of the public and of the local authorities by Sir James Kitson's committee. He urged that these clauses afforded every reasonable protection to the municipalities who were now petitioning against the Bill, and that they should not be allowed to refuse wayleaves to the company through their districts if and when it was desired to reach places beyond.

The consideration of the Bill was then adjourned till Thursday.

SOME NOTES ON ENQUIRIES FOR ENGINES.*

BY J. A. SEAGER, STUDENT.

The following are a few suggestions for guidance in enquiring for an engine, which will be found to obviate much unnecessary correspondence, and facilitate the delivery of a satisfactory steam unit. It is remarkable how many omissions can be made in a single enquiry, apparently due, not so much to carelessness, as to a misunderstanding of the requirements of the engine-builder. It would add greatly to the quality of the work done, besides cheapening the price and reducing the time of completion of work, if the requirements of the customer could be made to agree more closely with the standard practice of the engineers. The present notes are limited to main engines, such as those used for mill machinery, electric power plants, steamship propulsion, etc.

Horse-Power.—It seems almost unnecessary to say that the horse-power of the engine should be stated. The brake horse-power should preferably be specified. In arranging for belt or rope driving, as a percentage of power is lost in transmission, a 5 per cent. increase should be made to the calculated brake horse-power of the engine for short single drives, longer drives or multiple drives, of course, involving a greater percentage loss. It should be mentioned whether the driving is to be by rope pulley, belt pulley, or half-coupling for direct driving.

Steam Pressure.—I have seen a few enquiries for engines from which the boiler pressure has been omitted, although it is obvious that an engine cannot give the same power with low as with high pressure steam. If no boiler has as yet been installed, the engine-makers should be asked to state the most suitable boiler pressure. If the boiler is already laid down, its working pressure, less the loss of pressure along the steam-pipes (which may be from 5lb. in short, well-designed lengths, to as much as 15lb. in long or crooked arrangements), should be stated in the enquiry.

Speed.—The question of speed has an important influence, not only on the size of the engine, but often on the type also. For example, high-speed engines—*i.e.*, from, say, 350 to 600 revolutions per minute—are now usually built vertical, and often with their cranks, connecting rods, valve motion, etc., enclosed. With slower speeds, however, horizontal engines with large cylinders and unenclosed mechanisms are employed, or in situations where ground

* Paper read before the Institution of Electrical Engineers (Students' Section).

Digitized by Google

space is begrudged (as on shipboard and valuable ground), these open-type engines are built vertically. It is not always possible to give the engine-maker much latitude as to speed at which he may run his engine, but wherever possible he should be allowed to select his own, or, at the very least, be given some slight range to choose from, in order that he may put in a standard, and, therefore, cheap, size which will run economically.

Condensing.—Although an economy can be effected by the use of a condenser, an engine should not be changed over from an atmospheric exhaust to a condenser without one is sure that it is mechanically strong enough to stand the strains due to increased difference of pressure on the faces of the piston, and the greater mechanical force transmitted at the same speed. For this reason the engine-maker should always be informed whether a condenser is to be used or not. Two other reasons may be cited: The distributing valves would be set differently for the two conditions, and possibly a smaller engine could be put in if it were to run condensing. With large-sized engines it is often advisable to have a separate condensing plant for each engine, the pumps for which could either be worked by the main engine or by small auxiliary engines. It is preferable, however, to leave this point to the engine-maker's discretion.

Description of Site, etc.—It would be disappointing if, after the engine was delivered, it was found to be too large in one of its dimensions for the space provided for it. The client should therefore either send a dimensioned sketch of his foundations, if supplied, or of the site, and also the height to roof, travelling crane, or other obstruction; or he should ask the engine-maker to send an outline drawing giving the main dimensions of the engine when tendering. If the engine is to be erected inside a building, it would be well to make sure that there is a door or other convenient opening large enough to admit the engine when it arrives. A description of the site should always be sent. For example, it is of interest to the engine-maker to know whether his engine is to be placed on board ship or on a concrete foundation, for in the latter case only will foundation bolts and plates be required. If the engine is to be erected by the engine people above or below ground level, this must be mentioned, as special lifting or lowering tackle will have to be provided. Details should be given as to the nature of the approach to the site—whether by land or water. In the former case it should be stated whether there is a road suitable for heavy traffic leading to the site; in the latter, whether there is a craneage wharf handy, and in both cases whether there is a travelling crane or other suitable means for handling the engine on site.

Erection.—In the matter of erection, however, the client has the choice of three alternatives: (A) giving the engine-maker the order to erect the plant complete on foundations to be supplied by the client if they are requisite, and giving the above information in full detail; (B) asking the engine-maker to quote only for skilled labour in erecting, the client himself providing all rough labour, cartage, etc.; (C) the client undertaking to erect the engine on site himself, in which case he should ask for quotations f.o.r. or f.o.b. at the nearest railway station or dock. The first method is the most costly, but usually ensures good work. The last is perhaps cheap, and the result may be good or bad according to circumstances. It should be understood that only under exceptional circumstances and by special arrangement will engine-makers allow in their price for building foundations for the engines, or for any masonry, builder, or joiner's work required, or for any excavating, cutting away, or making good again. If such work is required, it must be definitely mentioned in the enquiry, and care should be taken to see that the engineer has bound himself to do the work.

Combined Plants.—For many purposes where small powers and high speeds are required, such as centrifugal pumps, fans, electric dynamos, etc., it is customary to supply a direct-coupled set mounted on a common bed-plate, thereby cheapening the cost of erection. In such cases the engine-maker will supply the base-plate with his engine, and will, if requested, receive the apparatus to be fitted at his works, couple the same to his engine, and deliver the complete set ready for erection on the foundations. As a matter of fact, he will often undertake to supply the combined plant complete, fitting his engine to suit the needs of the fan or dynamo to be supplied on receiving particulars of the work to be done by the plant. This method of ordering is recommended to non-expert purchasers, as it saves trouble for the client, and throws the onus of failure or defect entirely on the engine-builder.

Tools, Accessories, and Spares.—A clause should be included in the enquiry calling for all necessary tools, accessories, and spares. A firm of good reputation will put in a suitable set without further information, but as a check the following items (though not forming a complete list) should be looked for: a complete set of spanners on rack, to be kept on rack except when being used on the engine, and any special tools required; spare springs and rings for pistons, and, if needed, valves; set of main brasses and smaller brasses; eccentric strap and governor springs if required; barring gear, tachometer, steam pressure and (if running condensing) vacuum gauges, etc. Cans, tanks, and filters for oil are not usually supplied by engine-makers. It should be specially stated whether steam and exhaust stop valves are required with the engine, or whether they will be supplied with the pipework. Engine-makers cannot be expected to connect their engine to steam, exhaust, or drain pipes unless this was arranged before signing the order, and if connecting pipes or bends have to be placed between engine and main pipes, the position of the flanges on the latter with relation to the engine should be indicated when asking for a tender.

Nature of Load.—Different types of engines, equally high class in workmanship, are designed with varying intent. Some are meant to withstand severe shock, such as is experienced in rolling mills; others, such as are used in cotton mills and electric generating stations, are required to give very uniform speeds under varying loads; others, again, where fuel and water are expensive, are designed to give extremely low water consumption and high efficiency; still others, destined to be placed in populous localities or on slight foundations, necessitate a careful balancing of moving weights to reduce vibration. If any such special conditions exist they should be stated, so that the engineer may form an opinion as to whether heavy framework, Corliss valve gear, three-cranked shaft, etc., are applicable. It should be carefully stated whether the direction of rotation of the engine is to be reversible or not, unless the particulars given of the work to be done imply one or other of these conditions as essential. If the engine is always to turn in one direction, it should be clearly stated which direction would be preferable, as "the engine to run clockwise (or counter-clockwise), as seen from the end of the crankshaft next the coupling or pulley."

Steam Consumption and Efficiency.—Where steam consumption and efficiency are important, makers should be asked to state a guaranteed value for these in their tender at, say, full and half load. These values should be tested when the engine is built, either at the engine-maker's works or on site. In the former case the client is at liberty to see the tests carried out and verify the results himself, or he can have a signed certificate of tested results. In the former case it almost goes without saying the travelling expenses of the client are not included in the engine estimate, and it would be a breach of courtesy at least to claim from the engine-maker any sums spent in this way. If the tests are conducted on site, all fuel and water required for the test should be supplied by the client. It should be noted that the efficiency of an engine when new is generally some 5 per cent. less than when it has been running a short time, as the piston rings and bearings have not then come to a proper bearing surface.

Speed Regulation.—A point respecting speed regulation should be explained for the benefit of those who require very good governing. It is customary to test the action of the governor by suddenly throwing the full load off the engine, and expressing the increase in speed as a percentage of the original speed. This percentage will be guaranteed by the builder if required, and in good engines will not be above 3 per cent. But it is an instant or two before the governers will "get hold" of the engine after the load goes off, and the speed flies up possibly over 10 per cent. above normal. This excess of speed, though lasting only

Digitized by Google

a short time (at most 10 seconds with good governors), would be sufficient to burn out a high-efficiency electric lamp if the engine were driving a dynamo, or break the threads in a spinning machine if the engine were running a mill. For this reason, the percentage of instantaneous, as well as permanent speed variation, should be asked for, if there is good reason for so doing.

Time of Delivery. — An engine-builder cannot keep a stock of engines, except possibly in small sizes, so that a period must be allowed him to complete his order. Since time is money, the client should ask in his enquiry for a guaranteed time of completion of work, which will obviate any misunderstanding as to what constitutes a reasonable time of delivery, and will enable him to discriminate between a maker whose shops are already too full of work and one who can supply the necessary power, labour, and room to get the work through quickly. Such guarantees are, of course, given subject to delay due to strikes, lock-outs, accidents, or other causes not under the control of the engine-maker.

Although the above considerations by no means exhaust the points which have to be remembered in ordering an engine—it would be unfortunate for the consulting engineer if they did—yet if those mentioned were attended to, the confusion of ideas which is apparent in many enquiries would be lessened, and the chances of getting a satisfactory engine much increased.

ALTERNATING-CURRENT INDUCTION MOTORS.*

BY A. C. EBORALL, ASSOCIATE.

(*Continued from page 89.*)

Several firms, notably the Oerlikon Company, avoid the squirrel-cage construction altogether by winding the rotor with closed coils. In this case the rotor winding may either consist of a regular wave winding, taken all the way round either once or else several times and finally short-circuited, or better, of a number of coils, or groups of coils, separately short-circuited. Such wire-wound rotors are naturally more expensive than either of the forms described above, and are frequently difficult to wind, on account of the trouble experienced in handling the heavy conductors.

The employment of wound rotors and non-inductive starting resistances is, as already indicated, always preferable for motors of any size. Here the rotors are invariably wound with a three-phase star-connected drum winding, which may be carried out either with overlapping (rectangular) coils, or with two or four bars per hole or slot, arranged as a cylinder wave winding. The common junction to the three phases of such a winding is frequently the ironwork of the rotor. This is very convenient with motors of considerable size, where the conductors are usually massive. Star-connected bar windings of this character are always unsymmetrical, and "false connections" have to be made in each phase. A point to be remembered when designing wound rotors for high-tension motors is the fact that the rotor volts per phase—that is, the voltage between any two slip-rings at normal stator pressure when the brushes are lifted off and the motor is at rest—must be kept down to a safe value: this is because at starting, with all resistances in, the voltage across each resistances (and the corresponding two rings) may be sufficiently large to be a source of danger to the attendant, if the turns in the winding have not been kept down; moreover, there is some risk of arcing taking place. On the other hand, in no case must the number of rotor conductors in series be too few, especially if the motor is of large size, else the cost of the starting box becomes excessive, and, if this latter is mounted on a switchboard, the three heavy cables coming to the latter may become inconvenient to arrange for; moreover, the contacts on the box may give trouble. It may sometimes happen that it is desirable to regulate the speed of a polyphase motor (by means of the rotor resistance) at a point situated a considerable distance away from the motor. In such a case, and if the motor is for a low voltage, it may pay to arrange the rotor windings to transform up, as it were, in order to effect a saving on the cost of the three cables coming from the rings to the starting box, but this must not be pushed too far.

Although it is the standard practice with one or two firms to build the starting resistance within the rotor itself, instead of employing a separate starting box and slip rings, it would seem that the latter practice is the better. The advantage of doing away with the external arrangement consists, of course, in getting rid of the sliding contacts. On the other hand, it is easy for the short-circuiting device (whether operated by hand through the hollow shaft or automatically) to get out of order, inspection of the contacts is difficult, and, above all, the motor is brought up to speed abruptly because a sub-divided resistance is practically out of the question; consequently, the effect on the pressure regulation of starting a motor so fitted under heavy load is bound to be greater than if the motor had been fitted with an external graduated resistance, permitting of easy and gradual starting. However, several firms are now engaged in studying this detail, and considerable improvements may be expected shortly in the electrical and mechanical design of internal starting gear.

(C) *Notes on Performance and Design.*—An analysis of the guaranteed performance of a given line of open or semi-enclosed induction motors between 2 b.h.p. and 100 b.h.p. built by any of the best Continental or American makers, and whose construction is on the lines indicated above, may be set forth as follows:

1. No-load Current. Expressed as a percentage of the full-load current, the values for this will be as under:

	Poly-phasers. Per cent.	Single-phasers. Per cent.
For motors between 2-5 b.h.p. inclusive.....	30	40
,, ,, 7½-20 ,, ...	25	30
,, ,, 25-100 ,, ...	20	25

2. Overload Capacity. This is sensibly the same for all sizes with a given line of motors run at constant stator pressure, and will be as follows:

	Polyphasers.	Single-phasers.
For one hour*	50 per cent.	Varies considerably, but generally small.
Before falling out of step...	90 ,,	

3. Full-Load Drop of Speed (Slip). At constant pressure on the stator terminals this will be:

For induction motors between 2-5 b.h.p. inclusive, 7 per cent.
,, ,, ,, ,, 7½-15 ,, 5 ,,
,, ,, ,, ,, 20-40 ,, 4 ,,
,, ,, ,, ,, 50-100 ,, 3 ,,

4. Heating. The final temperature rise after a long continuous run at full load will not exceed 40deg. C. for semi-enclosed motors having outputs between 2 b.h.p and 25 b.h.p., and 300deg. C. for larger sizes.

5. Full-load Efficiency. For semi-enclosed motors with hot windings the values for five representative sizes will be as follows:

	2 b.h.p. Per cent.	5 b.h.p. Per cent.	10 b.h.p. Per cent.	25 b.h.p. Per cent.	50 b.h.p. Per cent.
Polyphase motors ...	75	79	85	87	90
Single-phase motors.	73	77	83	86	89

6. Full-load Power Factor. The values for this quantity for five such representative motors will be:

	2 b.h.p. Per cent.	5 b.h.p. Per cent.	10 b.h.p. Per cent.	25 b.h.p. Per cent.	50 b.h.p. Per cent.
Polyphase motors ...	78	80	85	87	88
Single-phase motors.	72	75	80	83	85

7. Weight per Brake Horse-power. The net weight per brake horse-power—that is, not including the weight of the rails, pulley, and starting resistance, if any—of the five representative motors designed and constructed on the above lines will not come out much below the following values:

	2 b.h.p.	5 b.h.p.	10 b.h.p.	25 b.h.p.	50 b.h.p.
Polyphase motors ...	80	58	56	40	40lb.
Single-phase motors.	115	88	66	62	62

NOTE.—The values given in Nos. 1 to 7 above are for 50-cycle motors at voltages of 110, 220, 440, or 500 volts, having the following number of stator poles per phase:

All motors between 2-7½ b.h.p. inclusive, four poles.
,, ,, ,, 10-30 ,, six ,,
,, ,, ,, 40-100 ,, eight ,,

The various values, however, for 40 and 60 cycle motors having the same number of poles are practically the same as those given above.

A standard line of induction motors constructed on the lines already indicated, and to which the above figures relating to performance apply, would have the following general technical data:

1. Peripheral Speeds. 4,000ft. to 7,000ft. per minute, according to the size of the motor.

2. Ampere-conductors per inch of stator (inner) periphery at full load.

B.H.P.	Ampere-conductors per inch.
2 to 7·5	250
10 to 30	330
40 to 100	430
100 to 150	570
Above 200	600

* Paper read before the Institution of Electrical Engineers,

* The temperature rise not exceeding 70deg. C. for semi-enclosed motors, and less for open-type motors.

Digitized by Google

3. Flux Densities per square inch. In the stator teeth :

B.H.P.	Maximum value of B.
2 to 7·5	65,000
10 to 30	70,000
40 to 100	80,000
Above 100	85,000

In the rotor teeth :

B.H.P.	Maximum value of B.
2 to 7·5	80,000
10 to 30	85,000
40 to 100	90,000
Above 100	100,000

In the air-gap the flux density should never exceed 30,000 lines per square inch. The flux density in the stator core is determined solely by the permissible loss, and does not otherwise affect the performance of the motor. The above figures give very good results for 50 ~ motors having partly closed slots for both rotor and stator. With motors for higher frequency, and for hole-wound stators and rotors, smaller values must be taken.

4. Current Densities per Square Inch. With low and medium pressure semi-enclosed motors the amperes per square inch in the stator windings at full load will be between 1,500 and 1,100, according to size, while in the rotor bars the current density will be about 15 per cent. higher. With high-pressure motors, somewhat smaller values must be taken in the stator on account of the relatively larger space taken up by insulation.

5. Length of Air-gap. This is always to be made as small as possible, and is determined wholly by mechanical considerations. Usual values for the length of air-gap—that is, the distance from iron to iron—are :

Rotor diameter.	Air-gap length.
Up to 4in. inclusive	1-100in.
Between 5in. and 8in. inclusive	1-75in.
,, 9in. and 12in. ,,	1-50in.
,, 15in. and 20in. ,,	1-32in.
,, 24in. and 32in. ,,	1-16in.
,, 40in. and 60in. ,,	1-8in.

Although the above figures relating to the design of induction motors have been taken wholly from practice, it is perhaps necessary to point out that it is not possible to apply hard-and-fast rules and constants when designing such motors—experience in designing and a large quantity of experimental data for the type in question are absolutely necessary if the best results are to be obtained.

Part II.—Starting Devices for Single-Phase Induction Motors and some Notes on Recent Developments.

It is not too much to say that more attention has been given to the question of starting devices for single-phase induction motors than to any other problem connected with single-phase working. The first difficulty was to get such motors to start at all ; then, after this was overcome, there came the question of reducing the heavy starting current ; finally, it was sought to so improve the starting device as to permit of the motor starting against load, still with a moderate current consumption. In the six years during which the subject has been before electrical engineers, successive improvements have taken place, and it is to the latest development in single-phase motors that the author wishes more particularly to refer in this part of his paper—namely, the new motor of Mr. Alex. Heyland. Before doing so, however, it may perhaps not be out of place to consider very briefly the underlying principles of all single-phase induction motors, although, of course, there is nothing new to be said on the subject in these days.

It has already been stated that a single-phase induction motor is nothing more than a polyphase motor running on one phase. Let, for instance, a two-pole two-phase motor be running from two-phase mains without load. Neglecting (as may quite well be done) the trifling power current required to make up the motor losses (under these circumstances practically only iron, ventilation, and friction), the current read on an ampere-meter in each phase is the "magnetising current" of that phase of the motor—that is, it is the wattless current required for driving the magnetic flux through the magnetic circuits of the motor ; further, the speed is synchronous. Now let one phase be switched out. The motor will go on running as a single-phaser at practically the same speed, but the ampere-meter in the remaining phase will read approximately twice the current that it did before—that is, the magnetising current in this phase has doubled. What has happened is briefly as follows : The magnetic flux originally provided by the switched-out phase is now replaced by a flux of approximately the same value and relative position furnished by a magnetising current in the rotor. Magnetising currents are called into being in the rotor, induced by the magnetic flux of the phase still connected to the mains, and in quadrature with this flux with regard to time, and these currents are carried round nearly 90deg. in space by the practically synchronous rotation before reaching their maximum. Thus the cross-flux produced by them has very nearly the same effect as that formerly produced by the switched-out phase. The magnetising current in the rotor has, of course, to be balanced by a corresponding stator current, so that the ampere-meter reads the magnetising amperes of phase 1, plus the magnetising amperes of the rotor transferred to the winding of phase 1. Hence the magnetising current in the latter approximately doubles.

With this perfect motor running at synchronous speed, it would be found that a voltmeter connected to the terminals of the switched-out phase would give a reading equal to the pressure on the mains from which phase 1 is running. This E.M.F. is that induced by the cross-magnetisation of the rotor magnetising currents, and is in quadrature with the impressed E.M.F. of phase 1, as already stated. In commercial motors the E.M.F. of phase 2, measured in this way, is not quite equal to that of phase 1. The magnitude of the difference between the two voltages is a measure of the quality of the design of the motor. It has been said above that the motor continued to run as a single-phaser at practically the same speed. In reality the speed is a trifle less, the difference being too small to detect on a counter, owing to the fact that the rotor currents cause a slight slip, so that even a single-phase motor without friction and ventilation losses (unlike the polyphase motor) cannot run at a synchronous speed at no load.

Of course, as the rotor is loaded, the rotor power currents called into being by the load are magnetically balanced by corresponding stator currents (when the rotor and stator coils are coaxial, or approximately so), and the slip increases—that is, the speed departs more and more from synchronism. Owing to this latter circumstance the induced rotor magnetising currents are carried round in space less than 90deg. ; the cross-magnetisation produced by them is accordingly shifted from the most effective position, until with continually-increasing load there comes a point at which the torque due to the cross-field and the rotor load currents attains a maximum value—if this value is exceeded the motor pulls up. When the rotor is stationary the cross-magnetisation is reduced to zero ; there remains now only the one flux of the phase connected to the mains (phase 1), and this flux cannot possibly produce a torque—that is, the motor cannot start—because its axis (that is, the axis of the exciting coils of phase 1) coincides with the axis of the current-carrying coils of the rotor.

In order, therefore, to enable a single-phase induction motor to start at all, an auxiliary starting field must be created that will do exactly the same thing as the rotor magnetising currents do at synchronous speed—that is, with regard to space, a magnetic flux must be established in quadrature with the principal flux inducing the rotor currents ; and with regard to time, this auxiliary flux must coincide with the rotor load current—that is to say, it must be approximately 180deg. behind the corresponding stator current. Every single-phase induction motor must, therefore, be provided with a device to produce a suitable cross-flux in the air-gap, and the amount of starting torque available will depend purely upon the value of this cross-flux, and upon the effectiveness of its time relations as stated above.

All single-phase induction motors are provided with starting coils wound in the useless winding space of the stator. They rarely occupy more than one-third of the total stator winding space, and frequently less ; moreover, these coils are invariably so arranged that the magnetic axis of each coil is in quadrature to the magnetic axis of the corresponding running coil—a disposition exactly fulfilling the "space" requirement stated above. A notable exception to this disposition is the arrangement that has been used for many years by the Swedish firm of Wenström for their small single-phase motors, which have the starting coils "staggered" from the position indicated here. The difference existing between the various starting devices lies mainly in the various methods of producing the requisite phase relation of the cross-magnetisation.

With the exception of the Heyland motor, all the devices employed for producing this requisite phase difference are external to the motor, and they have all been devised at one time or another by Mr. C. E. L. Brown, and have gradually been adopted by all other single-phase motor builders. These external starting devices take the special form of arranging that the self-induction of the current, including the starting coils, has a much higher value than that of the circuit containing the running coils, this being attained by suitable winding proportions in conjunction with choking coils or non-inductive resistances or condensers, or any two of these in one or other of the stator circuits. The choice of such apparatus is governed by the relative value of the turns in the starting and running coils, and by the particular connections used at starting.

The starting torque given by motors arranged in this way is inconsiderable, barely sufficient, in fact, to run the motor up to speed against the load of belt and loose pulley. Moreover, unless the motor is very carefully designed—particularly from the magnetic leakage point of view—the starting current at this small torque will be excessive. With the above-named exception, the very best single-phase induction motors of the present day working under the most favourable conditions

Digitized by Google

require a current at starting at least equal to the full-load current in order to run them up to speed without the load, while against the full load they will not start at all, whatever the value of the starting current.

The principal reasons for these comparatively indifferent results are, that the phase difference at starting produced by the above-mentioned means is small, and that the cross-flux produced by the starting coils does not attain a high value. As with independent alternating-current circuits a large phase difference will be produced by increasing the self-induction of the circuit, it might be thought that this could also be obtained in a motor by arranging the starting device and starting coils on these lines. But it must be remembered that the stator circuits of an induction motor are not really independent, on account of the action of the rotor currents. These behave

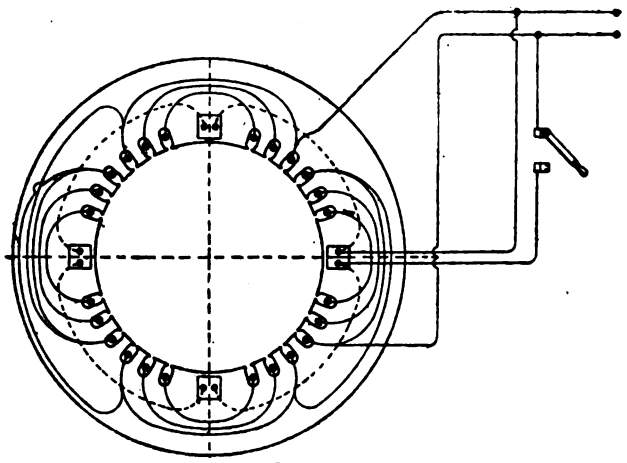

FIG. 7.

with regard to the stator currents just as the loaded secondary of a transformer behaves with regard to the primary—that is to say, the self-induction of the stator windings is more or less completely wiped out by the mutual induction of rotor and stator. It follows from this that better results will be obtained if the number of turns of the starting coils is kept low, and the increase of self-induction produced by an external choking coil, or equivalent device involving magnetic leakage. This point was recognised at an early stage by motor builders, and an external choking coil (to produce as much phase difference as possible) is a leading feature of several modern starting devices.

But this increase of self-induction, whether produced externally in this way, or by winding the starting coils with a large number of turns, effectually prevents the starting field of the motor—that is, the field in quadrature position to that of the stator running coils—from attaining that high value already shown to be absolutely necessary if a large starting torque is required. Where the self-induction is increased by increasing the turns of the starting coils, the strength of the cross-flux falls off inversely as the square root of the self-induction. If the choking coil is used, the strength of the cross-flux is diminished by an amount equivalent to the leakage flux of the coil, consequently it is evidently a clear fundamental point that to obtain a large starting torque the self-induction of the starting coils should be kept down as much as possible.

It has been hitherto generally held that the design of starting devices for single-phase induction motors should be such that the starting conditions should approximate as nearly as possible to the starting conditions of polyphase motors—that is, designers have aimed at the production of a rotary field at starting. Not only this, but every effort has been made to make this field as uniform as possible, by so proportioning the windings of starting and running coils as to produce two equal magnetic fluxes, and the production of a larger field by one or the other winding has been particularly avoided.

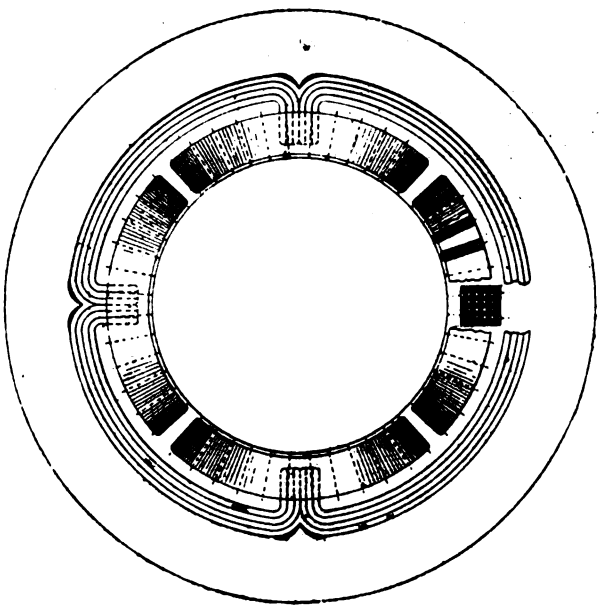

FIG. 8.

Mr. Heyland's motor, which is shown here to-night, and described below, is designed with regard to the starting device on exactly opposite lines to these. Briefly, there is no external phase-shifting device, the starting winding being put straight on the mains, and this winding has comparatively few turns, and is so arranged that under all circumstances its self-induction is less than that of the running coils—that is, the winding carrying the current of greater phase difference is made to have the smaller self-induction. As a result of the small self-induction of the starting coils, a cross magnetic flux of great strength is available, and this cross-flux is made to have the proper time relation by a special arrangement of the magnetic circuit of the stator. The production of a rotary field at starting is not aimed at, the whole idea of the starting device being to produce a powerful alternating magnetisation having the proper phase relation, in a direction (considering the two-pole case) at right angles to the axis of the running coils. The result is, that the Heyland single-phase motors will all start against full load quite easily, without an excessive current consumption, and it will be therefore readily admitted that an important advance has been made in single-phase motor work.

Apart from the design and arrangement of the starting device,

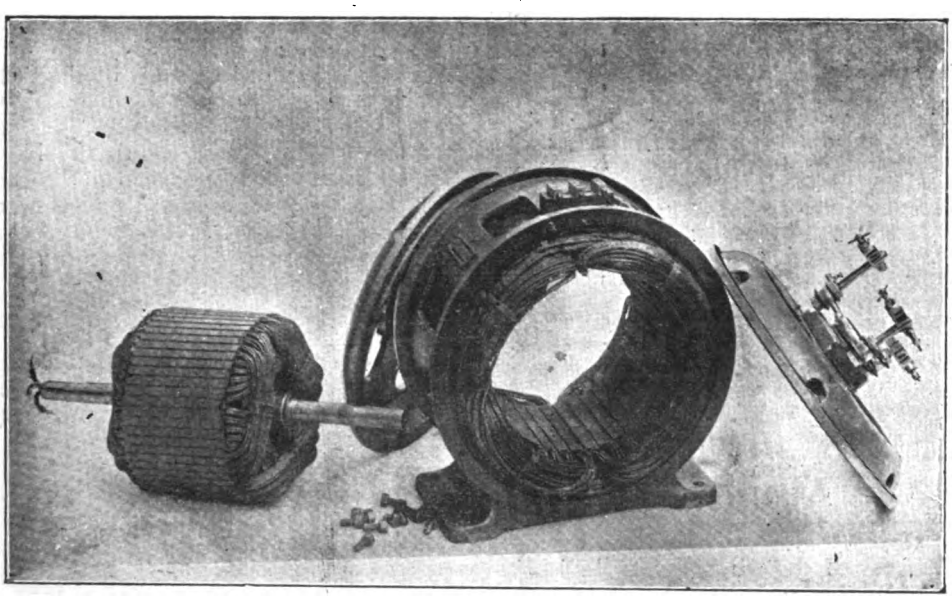

FIG. 9

Digitized by Google

the Heyland motors differ but little from other well-designed motors of the induction type. The stator running winding consists of a number of rectangular coils wound in half-closed slots in such a manner that magnetic leakage is as small as possible, while the rotor is wound with a regular three-phase star-connected winding, with its three free ends connected to slip-rings on the shaft, for the insertion of a starting resistance. A squirrel-cage rotor, or one of its modifications, could be easily used, but it has been found that the reduction of the starting current (for a given torque) brought about by the use of the resistance well repays its use, even for motors as small as 1 h.p.

Fig. 7 illustrates diagrammatically the stator windings of the Heyland single-phase motors, the figure illustrating a four-pole motor. The running coils are shown by the full lines and the starting coils by the dotted lines. These latter coils are wound in rectangular holes in order to obtain the necessary large phase difference of the current in them; the flux produced by these coils link very unfavourably with the rotor windings, which has the effect of reducing the mutual induction of the circuits in question, with the result that the current in the starting winding lags considerably, sometimes as much as 50deg.

Figs. 8 and 9 show clearly the arrangement of the stator running and starting coils as actually carried out for a four-pole motor, while the form of the rotor winding can be seen from the latter figure also. The motor is started as follows: all the rotor resistance being in circuit, the stator windings (both running and starting) are switched directly on the mains; the motor will immediately start up with great torque, and the rotor resistance and starting coils are to be cut out as it does so. The exact moment at which the latter are cut out affects only the starting current: if the motor is starting light, the single-pole switch can be opened when the arms of the rotor resistance are on the second contact; if it is starting against full load, the starting coils require to be left somewhat longer in circuit—that is, they are to be cut out, for instance, on the fourth or fifth contact of the starting resistance. The earlier Heyland motors were all furnished for use with a single-pole switch in the starting circuit. This has now been done away away with, however, by combining it with the starting resistance box (see Fig. 10), so that the operation of starting up is as simple as that with a shunt-wound direct-current motor.

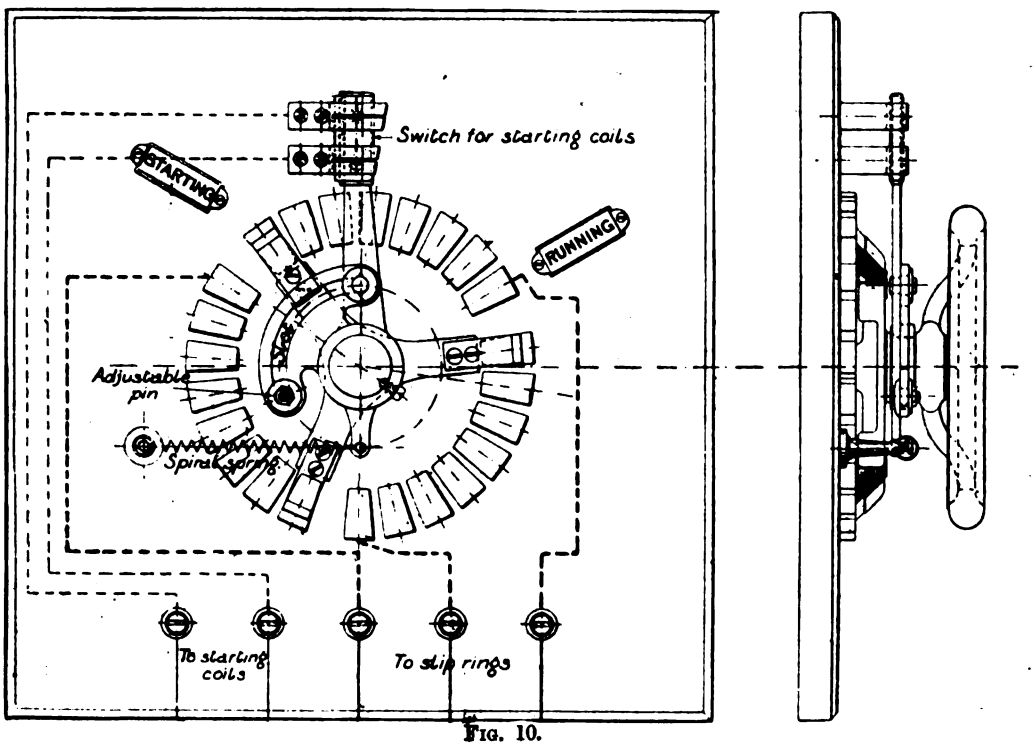

FIG. 10.

(To be continued.)

LIGHT RAILWAYS, FROM A COUNTY SURVEYOR'S POINT OF VIEW.*

BY H T. WAKELAM, A.M.I.C.E., COUNTY ENGINEER AND SURVEYOR OF MIDDLESEX.

In submitting the short paper invited by the secretary of the association, the author would state that amongst the many additional duties which have devolved upon county surveyors since the inception of county councils, on the passing of the Local Government Act, 1888, nothing has come under his notice of greater importance than the formulation of a light railway scheme under the Light Railways Act, 1896. In March, 1899, the author was asked by his Council "to consider in what way the County Council may, in the interest of the county at large, avail itself, as promoter, of the provisions of the Light Railways Act, and to prepare a scheme for that purpose accordingly." On giving the matter full consideration, the Parliamentary Committee of the Council was satisfied with the feasibility of such an idea, and of its proving a great success, both from a workable and financial point of view.

It will be remembered that the Tramways Act of 1870 confers no power by which county authorities may promote Tramway Bills in Parliament, and therefore the Light Railways Act of 1896 is the only legislative measure under which such authorities may seek power to construct lines, or, in other words, tramways. Such power being obtained under an order from the Light Railway Commissioners after a public enquiry has been held by them; the order having to be formally confirmed by the Board of Trade before it comes into operation. By the Public Health Act, 1848, all England, town and country alike, was for the first time brought under defined sanitary supervision, fairly comprehensive and complete. By the Public Health Act, 1875, advances were made in several directions, when urban and rural sanitary authorities received permanent recognition. The functions of each were gradually developed until 1888, when county councils were constituted by the Local Government Act.

There are now existing, as the result of the Local Government Acts, 1888 and 1894, three principal units of local government—viz, (*a*) county councils; (*b*) district councils; (*c*) parish councils. The term "county council," as you are all well aware, applies to the governing body of a county, and to any borough having a greater population than 50,000. Up to the passing of the Local Government Act, 1888, 15 Acts dealing with highways had been passed, commencing with the general Act, 1835. The Public Health Act, 1875, vested the powers and duties of surveyors of highways and of vestries, given under the Highways Act of 1835, in the urban authority. The Highways Act, 1878, abolished turnpike roads, and for the first time the county authority (then the justices sitting in quarter sessions) was called upon to contribute towards the cost of the upkeep of main roads. Section 11 of the Local Government Act, 1888, prescribes that all main roads shall vest in and be repaired by the county authority, unless district councils claim to retain power to carry out repairs requisite to the main roads lying within their areas, under which circumstances the county council shall pay the

* Paper read before the Incorporated Association of Municipal and County Engineers.

Digitized by Google

reasonable cost incurred. County councils, therefore, may rightly claim to be the authorities most interested in the upkeep and welfare of the main roads. The council the author has the privilege to serve, in an official capacity, was the first, and seems to be the only county authority, other than county boroughs, and the County Council of London, that up to the present has prepared an entire scheme and has sought to obtain orders from the Board of Trade to construct light railways, and to become primarily the tramways authority of the county.

The population of Middlesex has increased by leaps and bounds during recent years, and such a vast increase may be put down to: (1) the semi-metropolitan character of the county; (2) the lowness of rates; (3) the good administration of the various authorities; and (4) a gradual exodus of people caused by the acquirement of what were residential blocks in London for conversion into business premises. The great increase of population referred to has been the cause of speculative companies promoting the numerous applications for orders submitted to the Board of Trade, to empower the said companies to construct so-called light railways along the main roads. The introduction of electricity as a cheap motive power has no doubt also been a great factor in the promotion of the increased number of applications.

The County Council of Middlesex has always consistently opposed company-controlled undertakings, as being in direct opposition to the interest of the county at large. It is felt that the main roads are costly to maintain, and that the large profits that accrue from tramway undertakings should be enjoyed by the ratepayers, whose property the roads are, and that the lines of communication should not be given up to private companies. When it became known that the Board of Trade had determined to stand by their interpretation of the term "light railway," means presented themselves by which the county could be benefited; such an interpretation having already given a private company about six miles of tramways in the western portion of Middlesex at a much less cost than tramways could have been promoted. This also relieved the company of the restrictions placed upon tramways with regard to purchase by Section 43 of the Tramways Act, 1890. On the recommendation of its Parliamentary Committee the County Council of Middlesex decided by resolution to become the light railways authority, and adopted the author's scheme, which has a total length of about 103 miles, of which certain sections have already received the approval of the Light Railway Commissioners. The sections of the scheme already approved are entirely devoid of speculation, and will become a source of assured income from the date of their completion, owing to the terms of an agreement already settled with a company prepared to lease the lines. The Council have determined to construct the railways, but not to work them at present. Arrangements for leases to private companies will probably be made. It is considered advisable to do this instead of creating a special department to deal with the matter. Whatever its disadvantages, a lease, settled upon a profit-making basis, is less risky than forming a department entirely devoted to the supervision of a tramway system. Ratepayers may satisfy themselves that there is nothing speculative about an undertaking worked on such lines.

Middlesex may truly be termed semi-metropolitan in character, and it is of the utmost importance that as many travelling facilities as possible may be given to the enormous number of people who, more or less, live in the county of London, but sleep in the county of Middlesex. With this object in view the author's scheme included all the main arteries, so that direct communication may be had with, and running powers arranged over, any lines the County Council of London may construct. It was seen that grave difficulties would arise in creating a thoroughly workable and efficient system if the provision of light railways and tramways were left in the hands of private companies, and also if the local authorities promoted short lengths within the areas of their respective districts. These difficulties were also anticipated by such far-seeing men as the chairman of the Hornsey District Council and other representatives of local bodies, and projected railways within their districts were dropped in favour of the county scheme directly the extreme value of the latter was appreciated. Its inception and accomplishment are due to the foresight and energy of the very able and much-esteemed chairman of the County Council—Mr. R. M. Littler, C.B., Q.C. There is no doubt that, for advantages and convenient working, a uniform system under one authority is eminently the one to be desired. It appears to be the general opinion that county councils should take the place of private companies in light railway or tramway undertakings, and so relieve the ratepayers as much as possible of the cost they have to bear in maintaining their main roads. Light railways and tramways are, no doubt, a source of considerable profit, otherwise private companies would not so readily grant such concessions as those already offered by them in some parts of the county of Middlesex. There is no law by which companies can be compelled to cleanse and water the tracks laid down; and therefore, although the control of the track repair devolves upon the company interested, the cost of scavenging and watering devolves upon the Council, and it seems unfair to the ratepayers to allow speculators to take possession of what no doubt is, in most cases where the lines are laid, a source of considerable income to the promoters. It is seen that if companies can pay such large dividends and make such concessions as have been offered by them in various directions, the County Council of Middlesex may have very strong faith in its contemplated projects.

The effect of any county council becoming the light railway or tramway authority will be to enable that council not only to place at the disposal of the inhabitants within its area the best possible cars that can be purchased, and which can be kept free from the hideous advertisements and disfigurements which are invariably associated with company-controlled undertakings, but to provide cross-connections, which a company working solely for profit would not entertain. A county scheme can insure uniformity of rates and fares throughout the system. Cheap trams for workmen can be conveniently arranged and insisted upon. Cleanliness of the cars can be assured. A thorough system of supervision to ensure comfort in travelling can be instituted. The whole of the materials employed, the method of construction, and the positions of street standards can be prearranged with the district councils interested, without reference to the Board of Trade under arbitration clauses. Stopping places can be more conveniently arranged, after the due consideration necessary has been given to insure the requisite facilities for the ordinary road traffic—which is oftentimes altogether overlooked by private promoters. Regulations for rates of speed and punctuality can be framed and enforced, and fares for travelling on bank holidays, etc., can be definitely settled. The latter is a most important point—companies invariably charging exorbitant fares on these occasions. Double and single tracks can be laid, whichever appear most suited to the road widths, without large expenditures being cast upon the exchequer of the county by having to contribute to local widenings necessitated by companies carrying out short sections to the advantage only of the people resident in one or two districts, and not to the county as a whole. Private companies, as a rule, go for the "plums," which in a county scheme can be put in with the "paste," and still create a paying scheme and give greater advantages to the public than company-controlled undertakings are likely to give. Intercommunication, as already stated, can be provided, which with small schemes would be practically impossible; and last, but not least, equal benefits would accrue to the whole county, the profits, which undoubtedly would be reaped from such an undertaking, going towards the relief of the county rate.

There are many more minor considerations in favour of a county scheme that might have been treated, but as the secretary desired a short paper only, it has been the aim of the author to confine himself to the most important points, and to be as concise as possible in his remarks.

It is contrary to public policy to grant monopolies over main roads, and, therefore, if the latter are to be used for the purpose of light railways, the system laid down should, in the author's opinion, be as far as possible a complete one, and should be carried out by an authority representing

Digitized by Google

equally the interests of all districts within the area to be dealt with—in other words, the county council.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

291. I have a line shaft from which are driven various machines. This shaft is driven by two exactly similar motors, one at each end. An ampere-meter is in circuit with each. I note these two never read alike, but vary sometimes by 25 per cent., first one and then the other being the higher. How do you account for this?—M.

292. If a company supplying at 100 volts charge a dearer rate in the night time than in the daytime, would it be possible to charge two batteries of 55 cells each in parallel in the daytime and put them in series for part of the night time so as to make the meter rotate backwards, and so wipe out part or all of the record of the energy consumed at the dear rate in the earlier part of the night?—J. C. R.

ANSWERS.

Question No. 285.—In applying the pressure test to transformers, say with 6,000 volts between the primary winding and the secondary winding, core, and earth shield, and with 2,000 volts between the secondary winding and the core and earth shield, what reason is there for joining the primary winding to core and shield in the latter case?

Best Answer to No. 285 (*awarded* 10*s.*).—I gather from the question set by "C. W." that in the case before him there were two pressure tests made. In the first of these the secondary winding, the core, and the earth shield were all coupled together and 6,000 volts applied between them and the primary winding. In the second test the primary winding, the core, and the earth shield were coupled together and 2,000 volts applied between these and the secondary winding. The question in the mind of "C. W." seems to me to be as to why it is at all necessary to connect the primary winding on to the earth shield and core in the last test. Of course, in the previous test a voltage between the primary and secondary winding would have to be successfully borne of three times the value in the last test. At first sight it would seem, therefore, that it was quite unnecessary to couple the primary and core together, and I should not think that the conditions are likely to arise which would cause the transformer to break down on the second test. There is, however, in connection with all alternating-current apparatus a curious phenomenon known as "sparking across." This sparking across, or static discharge, occurs over distances corresponding to a voltage very much higher than anything which is applied. I have never seen a good explanation of this phenomenon, but should say that the coupling in the last test of the primary winding to the core is made with the object of ascertaining if under these conditions 2,000 volts will set up such a "sparking across" from the secondary winding to the primary and core. These static discharges do not, I believe, cause any appreciable waste of energy, but they are apt to heat up the path by which they travel, and in time to cause a complete breakdown in the insulation.—P. T.

Question No. 286.—Should high-tension mains for, say, 6,000 volts be laid in cast-iron troughs in preference to wood? And if so, why?

Best Answer to No. 286 (*awarded* 10*s.*).—This question evidently relates to a pitched-in system of mains. The voltage is extra high pressure, and the Board of Trade is very keen on using iron for this class of work. The answer depends principally upon the type of main to be used, bearing in mind that in anything like equal sections, creosoted wood is cheaper than cast iron, is almost as durable, but does not afford such protection from violence, and has not the quality of conducting leakage currents to the confines of earth. It is assumed that either lead-covered, concentric, or twin cables would be used, and that the lead covering would be metallically connected across the joints and to the outer or earth potential main at the generating station. In this case it would remain an open question to be settled by the comparative costs of, say, $\frac{3}{4}$in. creosoted timber and $\frac{1}{4}$in. cast iron in the particular district to be used. The durability and protectibility factors at that thickness are about equal, and the conductive effect not necessary. Where lead covering is not employed the conditions would not alter for concentric cables, but for a twin cable an iron trough would have to be used, in case an excavator's wedge came through and stirred up either cable. In this event the current would go to earth *viâ* the wedge and the trough, which would require to be bolted together at all joints, and connected to earth-plates at judicious intervals, to guard against rushing effects at bolted joints. Inductive effects are not considered, as with either twin or concentric cables they are imperceptible.—J. H. C. B.

PROPOSED NEW LONDON COUNTY COUNCIL TRAMWAYS.

We herewith give a list of the 28 new lines which, as mentioned in our notes, the Highways Committee of the London County Council are at present considering:

NORTH OF THE THAMES.

Archway Tavern (tramways terminus) to the county boundary in Archway-road.

Seven Sisters-road (existing lines), *viâ* Amhurst-park, to Upper Clapton-road (existing lines).

Mildmay-park (existing lines), westward, to Balls Pond-road (existing lines).

Harlesden (near the county boundary), *viâ* Scrubbs-lane, Wood-lane, Shepherd's Bush-road, Brook-green-road, and Fulham Palace-road, to Putney Bridge.

Uxbridge-road (near the railway station), *viâ* Richmond-road, Netherwood-road, and Westwick-gardens, to Shepherd's Bush-road.

Brook-green-road, at its intersection with Hammersmith-broadway, *viâ* that thoroughfare to Glenthorne-road (London United Tramways).

Victoria-embankment (Blackfriars end), *viâ* Victoria-embankment, Victoria-street, Buckingham Palace-road, Commercial-road, Bridge-road, and Chelsea-embankment, to the northern end of Battersea Bridge.

Battersea Bridge, *viâ* World's End-passage, Chelsea-embankment, New King's-road, King's-road, and Putney Bridge-approach, to and over Putney Bridge.

Hampstead-road (tramways terminus), across Euston-road and along Tottenham Court-road, to a point near Oxford-street.

Theobald's-road (tramways terminus), *viâ* Vernon-place, Bloomsbury-square, Hart-street, across Oxford-street, and along Shaftesbury-avenue, to Cambridge-circus.

Farringdon-road (present line), along that thoroughfare, to the City boundary.

Victoria-embankment, over Westminster Bridge, to Westminster Bridge-road (London County Council's tramways terminus).

Chelsea Bridge (north end), *viâ* Grosvenor-road, to a point near Lambeth Bridge.

SOUTH OF THE THAMES.

York-road, Wandsworth (South London Company's lines), *viâ* the new street in course of formation between York-road and Red Lion-street, along Red Lion-street, across High-street, along South-street, Garratt-lane, and Defoe-road, to High-street, Tooting (London County Council's lines).

St. John's-hill (South London Company's lines), *viâ* Strath-terrace, Bolingbroke-grove, and Bellevue-road, to the Surrey Tavern, at the junction of that road and Trinity-road.

Battersea Park-road (South London Company's lines) along Albert-road to the foot of Albert Bridge.

Camberwell-green (London County Council's lines), *viâ* Denmark-hill, Champion-park, Grove-vale, Lordship-lane, and London-road, to Devonshire-road, Forest Hill.

Goose-green, *viâ* East Dulwich-road and Peckham Rye, to the junction of Hall-road and Stuart-road, Peckham.

Digitized by Google

Southwark-street (South London Company's lines) at Hop Exchange Corner, *vid* Southwark-street, Stamford-street, York-road, and across Westminster Bridge-road, thence (single line) to Lambeth Palace-road (same company's lines), and returning *vid* Stangate over a proposed connection (No. 22), between London County Council's lines and the company's lines near Westminster Bridge-road.

Waterloo-road (London County Council's tramway terminus), along that road, to a point opposite York Hotel.

JUNCTION LINES.

Westminster Bridge-road (London County Council's lines), *vid* St. George's-road, to Lambeth-road (South London Company's lines).

Westminster Bridge-road (London County Council's tramways terminus) to terminus at Stangate (South London Company's lines).

Newington-causeway (London County Council's lines), *via* Dantzic-street, to Southwark Bridge-road (South London Company's lines).

Newington-causeway (London County Council's lines) to Borough-road (South London Company's lines), at junction with Southwark Bridge-road.

Newington-butts (London County Council's lines) to St. George's-road (South London Company's lines).

St. George's Church (London County Council's lines), *via* Marshalsea-road, to Southwark Bridge-road (South London Company's lines).

Great Dover-street (London County Council's lines) to Bermondsey New-road (London, Deptford, and Greenwich Company's lines).

Old Kent-road (London County Council's lines) to St. James's-road (London, Deptford, and Greenwich Company's (lines).

LEGAL INTELLIGENCE.

THE LONDON COUNTY COUNCIL v. THE NATIONAL TELEPHONE COMPANY.

In the Queen's Bench Divisional Court on Tuesday, before Mr. Justice Kennedy and Mr. Justice Darling, the case of the Attorney-General at the relation of the London County Council, and the London County Council against the National Telephone Company, came on for hearing. The London County Council claimed (1) a declaration that the company was not entitled to lay any pipes, wires, cables, or apparatus for the purposes of telephones under any of the streets in the county of London unless by license of the Postmaster-General under the Telegraph Acts, and with the consents required by those Acts; (2) an injunction to restrain the company, its officers, servants, and agents from opening or breaking up any street or public road within the meaning of the Telegraph Acts within the administrative county of London, or any part of such street or road for the purpose of extending the company's present system of underground pipes, etc., without the authority of the Postmaster-General and the consent of the London County Council; and (3) the company to pay the taxed costs. It will be recollected that the Attorney-General, at the instance of the County Council, filed an information against the National Telephone Company for opening and breaking up streets without the consent of the County Council and the Postmaster-General, and the County Council claimed the right to act as it had done. Pleadings were prepared for the purpose of trying the question.

The Attorney-General intimated that an agreement had been arrived at whereby the company acceded to the Council's claim, and therefore put an end to a long controversy.

RE THE CRYSTAL PALACE ELECTRIC SUPPLY COMPANY, LIMITED.

On Saturday last in the Chancery Division, Mr. Justice Kekewich had before him the petition of the Crystal Palace District Electric Supply Company, Limited, for the reduction of its capital.

Mr. Warrington, Q.C., said the petition first came before his Lordship on July 7, when he made an order that it should stand over for further evidence as to depreciation of assets. Mr. Chaplin had filed an affidavit on the general question whether the reduction would operate fairly towards the shareholders. The petition, as he understood it, was this: there was a fully paid-up share capital of £28,586, which it was proposed to reduce to £2,858, a loss of 18s. per share. There was a loss on working of £14,885, and there was a loss by depreciation of assets which amounted to £11,000 at least. In addition, there was a sum of £1,600, which appeared in the accounts of last year under the head of preliminary expenses and loss on working. That had been struck out in the loss account, and the accounts had been put in showing that this sum also was a loss on working.

Mr. Renshaw, Q.C., opposed the petition, on the ground that if the order were made it might prejudice the shareholders.

His Lordship, however, was satisfied that the loss had been honestly incurred, and sanctioned the reduction.

COMPANIES' MEETINGS AND REPORTS.

BRITISH THOMSON-HOUSTON.

The fifth ordinary general meeting of this Company was held on Monday at 83, Cannon-street, Mr. E. A. Lazarus presiding.

The Chairman said that they were very full of orders, and among those that they had in hand were orders from Birkenhead, Blackburn, Bristol city tramways, Croydon, Dublin city tramways, Glasgow, Huddersfield, Hull, Leeds, London United, Newcastle, Queenstown lighting, Sheffield, Tynemouth, Isle of Thanet, and several other places. At their works at Rugby satisfactory progress was being made, and he hoped that next time he had the pleasure of meeting them he would be able to tell them that they were in active work. As they were beginning to pay for part of the work, they had decided to make a call of £2. 10s. per share on Sept. 1, making £6 called up in all, and they would probably make the further call in two calls of £2 at intervals of two months, being the legal delay.

The report was adopted, and the resolution, "that dividends be now declared out of the net profits of the undertaking for the 12 months ending March 31, 1900, on the £240,000 ordinary shares, fully paid, a dividend of 10 per cent. for the year, on the £160,000 ordinary shares, of which £16,000 paid up from Aug. 15, 1899, a dividend at the rate of 10 per cent. for the year," was carried.

DIRECT UNITED STATES CABLE.

The forty-sixth ordinary general meeting of this Company was held at Winchester House on Tuesday last.

Mr. E. M. Underdown, Q.C., presided, and, in moving the adoption of the directors' report for the six months ended June 30 last, said the business done had been of a satisfactory kind. The half-year's revenue amounted to £52,204, as compared with £51,951 for the corresponding period of 1899. The working and other expenses for the same period, including income tax, amounted to £20 506, leaving a balance of £31,697 as the net profit, and making, with £6,347 brought forward, a total of £38,045. Three quarterly interim dividends of 3s. per share, amounting to £27,319, had been declared and paid during the financial year, and a final dividend of 3s. per share was now proposed, with a bonus of 2s. per share, making, with the three interim dividends, 3½ per cent. for the year, and showing a total distribution of £42,497.

Sir James Pender, Bart., M.P., seconded the adoption of the report, which was unanimously adopted.

METROPOLITAN RAILWAY.

The report of the directors of this Company states that the total receipts for the half year ended June 30 have been £444,565, and the expenses £201,087, leaving a profit of £243,477. The receipts show an increase of £18,625, and the expenses of £12,215, as compared with the corresponding half year of 1899. The directors accordingly recommend a dividend upon the ordinary stock for the half-year at the rate of £3. 15s. per cent. per annum, and to carry forward a balance of £30,767 to the next half year's accounts. The arrangements for an experimental working by electricity between Earl's Court and High-street (Kensington) Stations have been completed, and an electrical train has been working daily since May 21 last. In view of the importance to the Metropolitan and District Railway Companies of adopting electricity as a motive power, a committee consisting of three members from each of the Boards of the companies has been appointed to consider the question of applying electric traction to the working of the Inner Circle, and it has been agreed between the companies to invite eminent electrical traction firms to submit plans and specifications, with detailed estimates and tenders, for the necessary installation.

RAND CENTRAL ELECTRIC WORKS.

The report for the year ended Dec. 31 last states that, as a consequence of the war, communication with Johannesburg has for some time been exceedingly difficult, and at times altogether impossible. Owing to this circumstance the directors have not been in a position to render accounts and call the meeting at an earlier date. Business and mining work were brought to a standstill early in October of last year. It must be considered a favourable feature that the Company was at least able to pay its expenses during the last quarter of the year under review. Had the war not interfered with the Company's operations, a more favourable statement of working would no doubt have been submitted. The total revenue received amounted to £50,674 as compared with £43 208 in 1898, and the working costs to £49,834, as compared with £48,951 in 1898. The receipts for power supplied amount to £49,640, against £42,723 received in 1898. The installed power rose from 1,846 h.p to 2,219½ h.p. Under the equipment contract Messrs. Siemens and Halske guaranteed that the profits of the Company should be sufficiently large to provide dividends of 6 per cent., 8 per cent., and 10 per cent. per annum respectively for the years 1897, 1898, and 1899. The necessary amounts to provide the guaranteed dividends for 1897 and 1898 were duly paid, and the one now under consideration is due; but in regard to the profits for 1899, Messrs. Siemens and Halske claim a partial release on account of the hostilities in South Africa constituting a case of *force majeure*. The Board propose a basis of adjustment in respect of the profits of 1899, under which the sum of £21,872 will be receivable from Messrs. Siemens and Halske. Since under the

Digitized by Google

agreement with the contractors the sums received from them must be divided among the shareholders, the directors propose that a dividend of 7½ per cent. be declared for the year 1899, payable when and so soon as the necessary payment by Messrs. Siemens and Halske is made.

GLOBE TELEGRAPH AND TRUST.

The report of the directors of this Company for the year ended June 18 states that the net revenue amounts, with £1,091 brought forward, to £199,511. From this there has been distributed £132,322 in interim dividends, leaving an available balance of £67,190. The directors recommend a final dividend of 3s. per share on the preference shares, and of 4s. 6d. per share on the ordinary shares, making, with previous distributions, a total dividend for the year of 6 per cent. upon the preference and 5½ per cent. net upon the ordinary shares, leaving £933 to be carried forward. During the year the Eastern Extension, Australasia, and China Telegraph Company, Limited, and the Commercial Cable Company have both issued new share capital, which was offered to the shareholders of those companies *pro rata* to their holdings, the former at £13 per share and the latter at par. The full number of shares thus offered has, in each case, been taken up by this Company, the cost being met by the sale of other securities. The 4 per cent. debenture stock of the Western and Brazilian Telegraph Company, Limited, held by this Company has been exchanged for 4 per cent. perpetual debenture stock of the Western Telegraph Company, Limited.

LIVERPOOL OVERHEAD RAILWAY.

The accounts of this Company for the past half-year show an available balance of £14,202, and the directors have resolved to recommend payment of a dividend at the rate of 5 per cent. per annum on the preference shares, and 3 per cent. per annum on the ordinary shares, against 2½ per cent. per annum on the ordinary shares for the corresponding period last year. The balance carried forward is £4,452, as against £4,320 last year.

ALUMINIUM.

The report for nine months ended March 31 shows a profit of £19,684. The directors recommend a dividend at the rate of 15 per cent. per annum for the nine months, leaving £11,697 to be carried forward. The directors have considered proposals made for the amalgamation of this Company with the Castner-Kellner Alkali Company, and they have entered into a provisional agreement for the sale to the Castner-Kellner Alkali Company of all the property of this Company other than the shares of the Castner-Kellner Company held by this Company.

CITY AND SOUTH LONDON RAILWAY.

Report of the directors (with abstract of accounts) for the half-year ending June 30, 1900, to be submitted to the half-yearly ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on July 31, at 12 noon:

The receipts from all sources for the past half-year have amounted to £35,144. 18s. 2d., and the cost of working has been £20,860 12s. 8d., leaving a profit of £14,284. 5s. 6d. Inclusive of the balance brought forward from Dec. 31 last, the net revenue account shows an aggregate total of £18,366. 12s. 2d. After making provision for the debenture stock interest, a balance remains available for dividend of £13,215. 4s. 7d. Out of this sum your directors recommend that the full dividend of 5 per cent. per annum be paid on the preference stocks, 1891, and four months on those of 1896 (the other two months being charged to capital as authorised), and that a dividend at the rate of 1½ per cent. per annum be paid upon the consolidated ordinary stock, leaving a balance of £788. 2s. 11d. to be carried forward to the next account. The following table shows the number of passengers, exclusive of season-ticket holders, carried since the opening of the railway in each half-year:

Half-year ended	Number of passengers (exclusive of season-ticket holders).	Receipts (including season tickets).
Dec. 31, 1890 (11 days)	165 000	1 568 3 9
June 30, 1891	2,412,343	19,403 6 9
Dec. 31, 1891	2,749,056	19,978 16 6
June 30, 1892	2,813,162	20 931 4 2
Dec. 31, 1892	3,117,602	22 002 17 5
June 30, 1893	3,146 656	22,458 6 9
Dec. 31, 1893	3,093,351	22,067 14 10
June 30, 1894	3 383 154	23 564 10 6
Dec. 31, 1894	3 275,649	23 540 12 4
June 30, 1895	3 113,199	23,711 5 8
Dec. 31, 1895	3,172.438	23,780 3 7
June 30, 1896	3,192,672	24,021 13 0
Dec. 31, 1896	3,368,480	25,456 6 9
June 30, 1897	3,437,810	26,403 3 6
Dec. 31, 1897	3,337,861	25,472 12 10
June 30, 1898	3,478,977	26,356 16 4
Dec. 31, 1898	3,462,814	26 319 14 10
June 30, 1899	3,540,098	26,749 3 0
Dec. 31, 1899	3 442 942	26,197 14 10
June 30, 1900	4,169,717	33,608 2 3
Total since the opening of the line	61,872,980	£463,412 9 7

Your directors regret the diminution in the dividend, which is largely attributable to the increase in the debenture and preference charges before the recently opened extensions have had time to develop their traffic. There has also been a considerable increase in the cost of coal, wages, and materials. Your directors have the pleasure to report that the extensions to Moorgate-street and Clapham Common were opened for traffic on Feb. 26 and June 4 respectively. The receipts have already been considerably augmented, and are steadily improving. The extension to Islington is being rapidly proceeded with, and it is hoped will be ready for opening about March next. Both tunnels are nearly completed, and the stations are progressing. The Central London Railway not having yet been opened for public traffic, the joint subway constructed for the exchange of traffic between the two companies at the Bank Station has not been brought into use. The joint subway with the Brighton Company at London Bridge is in course of construction. The important additions and alterations at the generating depôt, alluded to in previous reports, are practically completed, and the further plant required for the Islington extension is in hand. In preparation for the opening of this portion of the line 10 additional locomotives have been ordered. The Bill promoted by this Company in the present session has received the Royal assent. The consent of the proprietors was obtained to an arrangement between this Company and the Baker-street and Waterloo Railway Company, who are obtaining powers to extend their line to the Elephant and Castle Station, where it is proposed to have a subway communication between the two systems, which will, it is hoped, result in a large exchange of traffic. The interests of your Company are fully protected. At the extraordinary meeting resolutions will be submitted varying the present agreement with the City and Brixton Company with the view of facilitating the raising of the capital of that company. The station buildings at Moorgate-street being nearly completed, the offices of the Company will be removed there immediately. The upper floors of the building have been let at remunerative rentals. It is proposed to redecorate and otherwise improve the present offices at 46, King William street, with a view to letting them until they are taken over by the City and Brixton Company. It is with much regret that your directors have to report the death of their colleague, Mr. Sampson Hanbury. He had been a director of the Company from its formation, and took a very earnest and active interest in its affairs.

CROMPTON AND CO.

Directors: J. Trotter, Esq. (chairman); R. E. B. Crompton, Esq. (managing director); B. Gibson, Esq.; C. F. Tufnell, Esq. F. R. Reeves, general manager.

Twelfth report of the directors (with abstract of accounts) to be presented at the annual general meeting of the shareholders at the City Terminus Hotel, Cannon-street, E.C., on July 30, at 3 p.m.:

After providing for debenture interest, payment of interim

Digitized by Google

dividend, and other items set out in the revenue account, there remains, with the sum brought forward from last year, a balance of £24,636. 14s. 10d. The directors propose to set aside the sum of £2 500 as a provision for doubtful debts, to place £12,000 to the reserve fund, to pay a dividend at the rate of 9 per cent. per annum for the half-year, free of income tax, making, with the interim dividend paid in January last, 7½ per cent. for the year, and to carry the balance, £3,729. 18s. 11d., forward. With the above addition of £12,000 the reserve fund will now stand at £25,046. 9s. 9d. The directors propose to set aside from this account a sum of £5,000 as a special contingency fund, to provide for any possible shrinkage in the value of investments, to write off £5,000 from the goodwill account, £5,000 from the patents account, and £3,000, balance of the cost of establishing the electric cooking department, carrying the balance, £7,046. 9s. 9d., forward. The whole of the 21,902 shares offered for subscription in July last year, were taken up, and the premiums have been carried to the reserve fund. The Board have purchased an additional 10½ acres of freehold land adjoining the site of the new works. They have considerably extended the main shop at these works, which is now being equipped with the necessary machinery, and have also erected a detached pattern store. The business of the Company continues to progress in a most satisfactory manner, and the order book is very full. The Chelmsford Electric Lighting Company have hitherto been occupying a portion of the old works at Chelmsford for a generating station; a formal conveyance of the freehold, together with the plant and machinery therein, has now been made to the Company, thereby nominally increasing the investment in that undertaking, the full amount of which is set out in the accounts. The administration of that company has been thoroughly reorganised during the past year, and it is believed that the results for the current year will show very considerable improvements. This undertaking, which is owned by Crompton and Co., Limited, is earning a moderate but steadily increasing revenue, and the directors are of opinion that this improvement will continue. In accordance with the articles of association, Mr. John Trotter retires from the Board of directors by rotation, but offers himself for re-election. The auditors, Messrs. J. H. Duncan and Co., also offer themselves for re-election.

EDISON AND SWAN UNITED ELECTRIC LIGHT.

Directors: J. S. Forbes, Esq. (chairman); the Earl of Lichfield; Major S. F. Page; J. W. Swan, Esq., F.R.S.; E. Villiers, Esq.; W. P. J. Fawcus, Esq.

Seventeenth annual report of the directors (with abstract of accounts) for the year ending March 31, 1900, to be presented to the shareholders at the ordinary general meeting to be held at the Cannon-street Hotel, E.C., on July 31 at 12 noon:

The profit and loss account shows a credit balance of £43,388. 1s. 5d. Providing for the interest upon the debenture stock, there remains a balance of £29,208. 11s. 11d. available for distribution. An interim dividend at the rate of 6 per cent. per annum having already been paid in respect of the half-year ending December, 1899, a further payment at the rate of 6 per cent per annum for the second half is recommended, making the dividend for the book year 6 per cent. per annum, the balance of £6,199. 18s. 5d. being carried forward. The issue of the £100,000 5 per cent. second debenture stock was duly made and fully subscribed. A quotation has been granted by the Stock Exchange. James Staats Forbes, Esq., and the Right Hon. the Earl of Lichfield retire by rotation from the Board, and offer themselves for re-election. Messrs. Welton, Jones, and Co., the auditors, offer themselves for re-election.

EASTERN TELEGRAPH.

The fifty-sixth half-yearly ordinary general meeting of this Company was held last week at Winchester House, E.C., the Marquis of Tweeddale presiding.

The directors recommended the declaration of a final dividend on the ordinary stock for the year ended March 31, 1900, of 1½ per cent., and a bonus of 2 per cent., making, with three previous payments on account, a total distribution of 7 per cent. for the year. Interest on mortgage debenture stock absorbed £27,590, and dividends on preference stock, £30,946.

The Chairman, in moving the adoption of the report, said the gross revenue for the half-year was £543,684, showing a general increase from all important traffic centres, especially from South Africa, but India again showed a decrease. The tariff between the Colonies of South and Western Australia and Tasmania and Europe had been reduced from 4s. 9d. to 4s. per word on May 1 last, with proportionate reductions for Government and Press telegrams. The agreement with the Australian Colonies also provided for future reductions under certain conditions to a minimum of 2s. 6d. per word. There would also be substantial reductions in the tariff between the contracting Colonies and South Africa when the new cables between Durban and Perth were opened. Negotiations were also going on with a view to a reduction in the tariff between Europe and India.

Sir J. Wolfe Barry seconded the report, which was adopted.

ANGLO-AMERICAN TELEGRAPH.

The report of this Company states that the total receipts from Jan. 1 to June 30, including the balance of £1,355 brought forward, amounted to £186 526. The traffic receipts show an increase of £982 as compared with the half-year ended June 30, 1899. The total expenses for the half-year amount to £60,784. The directors have, before declaring the net profits, set apart £12,000 to the renewal fund, leaving a balance of £113,742. One quarterly interim dividend of 15s. per cent. on the ordinary stock, and of £1. 10s. per cent. on the preferred stock, was paid on May 1, 1900, absorbing £52,500, and a second quarterly dividend of 15s. per cent. on the ordinary stock and £1. 10s. per cent. on the preferred stock, amounting to £52,500, will be paid on Aug. 1, 1900. A balance of £8,742 will be carried forward.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Blackburn.—The Corporation invite tenders for the supply and delivery of one traction switchboard. Tenders by Aug. 6. Details in our advertisement columns.

Bradford.—The Corporation invite tenders for the works required in extension of the electricity works, Valley-road, Bradford. Tenders by Aug. 2.

Belfast.—The Electricity Committee invite tenders for the supply and erection of an auxiliary feed-water heater with pipe connections. Tenders by Aug. 15.

Stockport.—The Tramways Committee invite tenders for 20 double-deck tramcars, complete with electric equipment for overhead traction. Tenders by Aug. 31.

Darlington.—The Corporation invite tenders for the supply and delivery of arc lamp posts and brackets. Tenders by 28th inst. Details in our advertisement columns.

Bradford.—The Guardians invite tenders for the installation of electric lighting at their union workhouse. Tenders by Aug. 13. Details in our advertisement columns.

Halifax.—Tenders are invited for mechanical stokers suitable for Babcock boilers. Particulars to be obtained from Borough Electrical Engineer, Foundry-street, Halifax.

Rugby.—The Urban District Council invite tenders for taking a lease of their powers under the Rugby Electric Light Order, 1898. Tenders by Aug. 1. Details in our advertisement columns.

Salford.—The Corporation invite tenders for the supply, delivery, and erection of lighting cables, tramway feeders, and street lighting. Tenders by Aug. 13. Details in our advertisement columns.

Barnes.—The Urban District Council invite tenders for the supply and erection of pipework, condensers, etc., and overhead travelling crane. Tenders by Aug. 14. Details in our advertisement columns.

Extension of Time.—The time for sending in offers for the whole or part of an electric generating machine for the Port Said lighthouses and the tools for the lighthouses' workshop at Alexandria, Egypt, has been extended to Aug. 1.

Hapton.—Tenders are invited for the lighting of Hapton township with electricity from Sept. 1, 1900, to April 30, 1901. Endorsed tenders to be sent to Mr. Ed. O'Shaughnessy, clerk to Hapton Parish Council, 16, Hammond-terrace, Padiham, by 31st inst. Full particulars on application.

Torquay.—The Corporation invite tenders for two water-tube boilers, with superheaters, two inductor alternators and Willans engines, pipework, surface condensers, etc., extension to high-tension switchboard, wattmeters, etc., and transformers. Tenders by Aug. 6. Full details in our advertisement columns.

Madrid.—The Spanish Government invite tenders, not later than Aug. 18, for the concession of a system of electric tramway lines in Barcelona. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between 11 a.m. and 5 p.m.

Russia.—Tenders are invited by the Russian Government not later than the 28th prox. for the telephone service of Warsaw, St. Petersburg, Moscow, Odessa, and Riga. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 5 p.m.

Grays.—The Urban District Council invite tenders for the supply, delivery, and erection of the following work in connection with the electric lighting of the district: (Section A) two Lancashire boilers and pipework; (B) two 100 kw. steam dynamos, with boosters and balancer; (C) fuel economiser; (D) switchboard; (E) battery; (F) travelling crane; (G) mains and street lamp fittings. Tenders by Aug. 9.

London, W.—The Central Electric Supply Company invite tenders for the supply, delivery, and erection of (Specification 2A) dry-back marine boilers, 11ft. 6in. diameter and 14ft. long, gangways, feed and drain pipes, etc., complete, as required for each of three blocks of boilers. Each or all of the blocks can be tendered for, each block containing six boilers. Tenders are also to be submitted for mechanical stokers, with the shafting and gearing for driving them. Alternative tenders are invited for (Specification 2B) water-tube boilers as an alternative to the dry-back marine boilers, including the mountings, feed and drain pipes, etc. Copies of the specifications, with forms of tender, drawings, and general conditions, can be obtained from the General Manager, 19, Carnaby-street, Golden-square, W., on payment of £3. 3s., to be returned on receipt of a bona fide tender. Specifications and drawings can be seen at the office of Prof. Kennedy, 17, Victoria-street, S.W. Tenders, on the prescribed form, endorsed on the outside "Electric Plant—Tender to No. — Specification," must be sent to Mr. F. J. Walker, general manager, before 10 a.m. on Aug. 20.

London, E.C.—Tenders are invited by the Pacific Cable Committee on behalf of her Majesty's Government and the Governments of Canada, New South Wales, Victoria, New Zealand, and Queensland for the manufacture and laying in the Pacific Ocean of 8,272 nautical miles of telegraph cables between Vancouver and Fanning Island, Fanning Island and Fiji, Fiji and Norfolk Island, Norfolk Island and New Zealand, Norfolk Island and Queensland. It is proposed to divide the whole undertaking under three distinct contracts, for any one or more of which contractors may tender. Each of these contracts will include a clause under which the contractor guarantees the good electrical condition and working order of the cables for 30 consecutive days after the completion of the laying. A fourth contract is also proposed for surveying and sounding the whole route before the cables are laid. Forms of contract, specification, and tender may be obtained of Messrs. Clark, Forde, and Taylor, 4, Great Winchester-street, E.C., at whose offices charts showing the proposed route of the cable and the positions where soundings are to be taken may be inspected. The last day for the reception of tenders is Aug. 14. They must be enclosed in sealed covers, marked "Tender for Pacific Cable," must be addressed to Messrs. Clark, Forde, and Taylor, 4, Great Winchester-street, E.C., and must be delivered by 12 noon on that day.

RESULTS OF TENDERS.

Bridgwater.—The Town Council have received the following tenders for their electrical undertaking, of which those marked with an asterisk have been accepted, subject to the approval of the Local Government Board:

Beckenham.—The Council have been recommended to accept the following tenders: For the institute—lead-covered cables, R. Dawson, £240. 13s. 5d.; for the baths—conduit system, Tamplin and Makovski, £27. 4s.

BUSINESS NOTES.

TRACTION.

Lancaster.—The Tramways Committee have reported in favour of the overhead trolley system of tramways.

North Staffordshire Tramways Co.—A general meeting of this Company is to be held at Donington House, W.C., on Aug. 2.

Paisley.—The Town Council have decided to recommit their Tramways Bill, which was recently thrown out by a committee of the House of Commons.

London County Council Trams.—The Chelsea Vestry intends, we understand, to oppose the proposed tramway from Blackfriars to Putney. The line would pass along the Chelsea Embankment.

Kirkcaldy.—Prof. Kennedy has lately made several visits to Kirkcaldy with regard to the arrangements in connection with the tramways, the line of the route receiving his special attention. From the preliminaries already receiving attention, it is evident that no time is to be lost in inaugurating the system.

Kingston.—The Light Railway Commissioners sat on the 23rd inst. at Kingston, and, after hearing the opposition offered by the local authorities and the Surrey County Council, intimated that they could not see their way to grant the order applied for by the British Electric Traction Company to construct electric tramways in the district.

Bournemouth.—After considering the report on the electric tramways, presented by Messrs. Lacey, Clirehugh, and Sillar, the Corporation have decided to adopt the system suggested and to apply for a provisional order for this purpose. The estimated cost of the system is £166,500, and the scheme of electric lighting in connection with the tramways is estimated at £11,640.

Morecambe.—A scheme is being promoted by Mr. John Gardner, of Morecambe, for the provision of an electric tramway from Lancaster to the West End of Morecambe. At present the West End is not particularly easy of access by either train or tram from Lancaster. The electrically-propelled trams will, it is estimated, accomplish the journey to Lancaster in a quarter of an hour.

Devonport.—The Borough Council have decided to compulsorily acquire the lines of the Plymouth, Stonehouse, and Devonport Company. They propose to lease the tramways to the company for 21 years, the company to take the current for driving the trams from the Corporation. The Corporation can use the trolley posts also for electric lighting. Practically the whole of the tramways are to be relaid.

Bristol Tramways and Carriage Co.—The directors have declared an interim dividend to June 30 last at the rate of 7½ per cent. per annum, payable on Aug. 4 prox., against 7 per cent. for the corresponding period. The total receipts of the Company for the half-year have been £74 991, against £72,396, an increase of £2,595 over the corresponding period, whilst the number of passengers carried was 12,061,613, against 11,408,683, or an increase of 652 930.

Glasgow.—Sir Lewis M'Iver, in stating that the committee dealing with the Glasgow District Tramways Bill found the preamble not proved, informed those present that the committee desired to put on record that, in their view, the original scheme was a good one, and calculated to be of much service to the district, but it had been so mutilated and loaded with conditions, by conflicting interests, and the excessive demands of several local bodies, that it appeared to the committee to be wholly unworkable.

Calcutta.—We are informed that the Klein Engineering Company, of Manchester, have recently received through Messrs. Dick, Kerr, and Co., the contractors for the Calcutta electric tramways, an order for a Klein's condensing plant with patent fan draught cooling tower. The plant is designed to condense the exhaust steam from engines of about 2,000 h.p., and consists of a surface condenser with Edward's air-pumps and motor-driven circulating pumps. The cooling tower is of the latest type, specially designed for giving the highest efficiency in hot climates.

Dundee.—At a meeting of the Tramway Committee of the Town Council last week reports were submitted from General Yorke and Mr. Trotter, Board of Trade inspectors, on the electrical car service, and these were considered favourable. In his report General Yorke suggested that for the purpose of preventing accidents the life-guards and the cars should be improved, while Mr. Trotter stated that the electrical system was entirely satisfactory. An instruction was given to the tramway manager to communicate with the builders of the cars with the object of having the guards improved.

Central London Railway.—This line is to be opened for public traffic on Monday next, the trains commencing running from Shepherd's Bush at 5.15 a.m. and from the Bank at 5.20 a.m., stopping at all stations except Bond-street, the opening of which is temporarily deferred. The fares up to 7.30 a.m. will be 2d. return any distance, and from 7.30 a.m. to 12 p.m. 2d. single any distance. The tenth ordinary general meeting of the company will be held at the Holborn Restaurant on Aug. 8, at 12 noon, to receive the report of the directors and statement of accounts for the half-year ending June 30, 1900.

Bolton.—A meeting of the Tramways Committee of the Corporation was held last week, when the reports for the working of the tramways were considered. The committee ultimately approved of the "town circle" system proposed in the report of the traffic manager, Mr. H. England, subject to the approval of the General Purposes Committee, a special meeting of which is to be summoned. Mr. England's report shows in what way the tram service could be made better by means of different starting places and connections. By means of the scheme he proposes, the fares would be considerably reduced on most of the lines.

Govan.—A memorandum has been forwarded to the Burgh Commissioners asking that in the proposed system of electric traction the overhead trolley wire should be placed at a clear height of 23ft. from the ground, instead of the 21ft. 6in. new proposed. This is to enable tall loads to pass along the streets. It is, however, expected that the side pole arrangement will be adopted in Govan. This will allow one side of the street to be entirely free. At the junction of the side streets and the main thoroughfare the wires will probably be so constructed that they may be taken down, an arrangement that will also be in use at the entrance to the docks.

Durham.—At the quarterly meeting of the County Council the County Surveyor reported that the electric traction company had applied for powers to lay a light railway from a point 83 yards north-west of the junction of Crossgate and the North-road, Durham, to Meadowfield. The railway would be a single line of 4ft. 8½in. gauge. The surveyor's recommendation that the promoters should widen, at their own cost, the Stone Bridge and Langley Bridge, and that the roadway at several parts outside the city should be widened, was adopted. The railway, it was stated, could be worked by steam or electricity, and might be used for the conveyance of passengers, goods, minerals, parcels, or animals.

Bath.—At a meeting of the Urban Sanitary Authority last week the following resolution was adopted: "That, in accordance with the agreement with Sir James Sivewright and Leopold Hirsch, adopted by the Council at a meeting held on May 15 last, the Council do hereby approve of the application now being made to the Light Railway Commissioners by the Council, jointly with these parties, authorising the construction of light railways under the provisions of the Light Railways Act of 1896, upon the routes mentioned in such agreement, and conditions contained in such agreement, and that the seal of the Council be affixed to all documents necessary to carry this resolution into effect." The tramways referred to are to be electrical.

Newcastle.—At a meeting of the New Tramways General Purposes Committee held on Tuesday last to consider what fares should be charged on the new tramway system of the city, the committee divided the whole of the route into sections of two-thirds of a mile, for which a charge of ½d. was fixed. It was proposed to recommend the Council to sanction the erection of galvanised iron car-sheds on ground adjoining the site of the new car-sheds in Shields-road. The estimated cost of these proposed sheds, which will provide standage for 40 cars, is £4,000. It was also proposed to have stopping stations at all the less congested parts of the route. The cars, as on other electrical systems, will be only stopped at these fixed points for the taking up and the alighting of passengers.

Wrexham.—At a special meeting of the General Purposes Committee of the Town Council the chairman read a notice from Messrs. Evan Morris and Co., on behalf of the Drake and Gorham Electric Traction Power Company, stating that it was their intention to apply for an extension of time for 12 months from Aug. 1 next for the commencement of the electric tramways in the borough, and for an extension of a further 12 months for the completion of the work, and asking if the Council had any objection. The Council decided that the time asked for be allowed, but informed the company that they had a very strong objection to the action of the applicants, and any further application of a similar kind would be most strongly opposed, as the Council had gone to considerable expense with regard to the provision of machinery to supply them with electricity, which would be lying idle for some months in consequence.

Liverpool.—On Tuesday afternoon last in Liverpool, one of the overhead wires on the Liverpool tramways, at the junction of Dale-street and the Old Haymarket snapped, and a serious interruption of the tram service took place. A breakdown gang from the Corporation works was soon on the scene, and the wires were raised from the ground and connected temporarily. Mr. Pugh, the traffic manager, was quickly in attendance, and he speedily got rid of the congestion of traffic. Another incident of a somewhat alarming character also occurred on Tuesday in Renshaw-street. As one of the cars was proceeding down the street, the trolley became detached from the wire and came in

Digitized by Google

contact with the cross stay attached to the street pole. The tubing of the trolley arm was torn away, with the result that it could not be used and the car had to await the arrival of the succeeding tram to assist it to a less crowded thoroughfare, whence it was removed by the electrical staff of the Corporation.

LIGHTING AND GENERAL.

Maryport.—The Urban District Council have succeeded in obtaining an electric lighting order.

Dover.—The Town Council have decided to again light the Granville Gardens with electricity instead of gas.

Lancaster.—The Town Council have decided to increase the cost of current per unit in consequence of the increased cost of coal.

Bournemouth.—The Town Council have decided to provide an extra circuit in the town for four arc lamps, at an estimated cost of £150.

Llandudno.—The Local Government Board have sanctioned a loan by the Urban District Council of £12,222 for electric lighting purposes.

Bath.—The proposed decrease in the price for electrical energy has been suspended by the Corporation until the cost of coal is not so great.

Chester.—The Electric Lighting Committee have decided to fix an electric radiator in a suitable room in the town hall by way of experiment and for exhibition.

Rochdale.—The electricity works of the Rochdale Corporation are, we gather, almost ready to start work, and are expected to give supply about the beginning of September.

Penistone.—The Board of Guardians are to receive a deputation on Aug. 9 from the Urban District Council in order to discuss the question of electric lighting in the Penistone district.

Uxbridge.—The Rural District Council have given their consent to the granting of a provisional order to the Northwood Electric Light and Power Company to supply electricity in the district of Ruislip.

Tewkesbury.—The Town Council have received notice from the North British Electricity Supply Company of their intention to apply for a provisional order to supply electric light in Tewkesbury.

City of London Electric Lighting Co.—We are informed that Mr. J. B. Braithwaite, jun., of 27, Austinfriars, E.C., and Mr. H. S. Leon, J.P., of Bletchley, have been elected to seats on the Board of this Company.

Wellington.—The Urban District Council have received a letter from the English Industrial Company, Limited, notifying their intention to apply for a provisional order to supply electricity within the Council's area.

Luton.—Messrs. Garrett and Co., of Dunstable, have informed the Rural District Council of their intention to apply for a provisional order for the supply of electrical energy in Houghton Regis and Upper West street.

Compagnie Generale de Traction (of Paris).—The directors have called up the remaining 75fr. per share upon their new issue of 100,000 shares, for payment on or before the 9th prox., with Messrs. Henrotte Fils et Cie., Paris.

Wombwell.—The District Council have received a notice from the North British Electricity Supply Company of their intention to apply for a provisional order to supply electric energy for public and private use in the Council's district.

Aberaychan.—At a meeting of the Urban District Council last week it was suggested, in consequence of a dispute with the gas company, that figures respecting the relative costs of electric lighting and gas lighting should be obtained.

Kensington.—The recommendation of the Special Electric Lighting Committee of the Board of Guardians, that the workhouse, infirmary, and offices in the Marloes-road be lighted with the electric light, has been referred to committee.

Cockermouth.—The Urban District Council have received a notice from the North British Electric Company of their intention to apply for a provisional order for electric lighting in the Cockermouth district. The matter was referred to a committee.

Removal.—In consequence of the growth of their business, Messrs. Babcock and Wilcox, Limited, have removed from 147, Queen Victoria-street to more commodious offices at Oriel House, Farringdon street, E.C., where all communications should be addressed.

Aspatria.—At the monthly meeting of the Urban District Council, the Clerk reported that formal notice had been received from the North British Electric Supply Company of their intention to apply for a provisional order to supply electric light within the Council's district.

Cullen.—At the monthly meeting of the Town Council a letter was read from the North British Electricity Supply Company, stating their intention to apply for a provisional order to authorise the company to supply electrical energy for public or private purposes in the burgh.

Glasgow.—At a meeting of the Corporation on Monday it was agreed that the remit to the Joint Committee on Electric Works be extended to enable the committee to consider and make a recommendation regarding the electric lighting of streets from centre poles and span wires.

Shildon.—The Urban District Council have received a notice from the Northern Counties Electric Supply Company of their intention to apply for a provisional order to supply the electric lighting of the Shildons. The matter has been referred to the Electric Lighting Committee.

London Gazette.—A first and final dividend of 15s. 5½d per £ has been declared *re* the Chitty Dynamo and Motor Company, Limited, 4, Hythe-road, Willesden, London, payable on any day (except Saturday) between 11 and 2 at official receiver's offices, 33, Carey-street, Lincoln's-inn, W.C.

Shrewsbury.—The recommendation of the Water and Lighting Committee, that the seven lamps now in use in Dogpole be lit by incandescent electric light in substitution for gas, has been adopted by the Town Council. The estimated cost of adapting the seven lamps, including laying the cable and all fixing, is £45.

Electrical Standardising, Testing, and Training Institution. As a result of the recent scholarship examinations, the following awards have been made by the board of control of the above institution: Mr. F. E. Berry, Wellingborough School, Maxwell Scholarship, value 50 guineas, tenable for two years; and Mr. A. W. Scrooby, of Dunheved College, a prize value 20 guineas.

Stock Exchange.—The Stock Exchange Committee has ordered the undermentioned securities to be quoted in the official list: Babcock and Wilcox, Limited—440 000 ordinary shares of £1 each fully paid, Nos. 1 to 440,000; and 100,000 6 per cent. cumulative preference shares of £1 each fully paid, Nos. 1 to 100,000, in lieu of the ordinary and preference shares of old company now quoted. Westminster Electric Supply Corporation, Limited—further issue of 29,437 ordinary shares of £5 each, £2. 10s. paid, Nos. 80,001 to 109,437.

Fatal Boiler Explosion.—We gather that on Wednesday afternoon an explosion occurred on the premises of the Crystal Palace District Electric Supply Company at Springfield-road, Upper Sydenham. The great boiler burst and wrecked two large buildings. At the time of the explosion five men were working in the place, and one of these, named William James Philbrook, was instantly killed. Two other men were found to have been severely injured. The explosion was followed by a fire, which before being put out damaged some of the surrounding buildings.

Charing Cross and Strand Electricity Supply Co.—The directors of the Charing Cross and Strand Electricity Supply Corporation, Limited, have, after providing for debenture and other interest and dividend on preference shares, declared an interim dividend at the rate of 8½ per cent. per annum for the half-year ending June 30, 1900, and carry forward £10,508. The interim dividend for the corresponding period of the year 1899 was at the rate of 8 per cent. per annum, with a carry forward of £8,300. The lamps connected during the past half-year have amounted to the equivalent of 24 242 8 c.p. lamps.

"New Lamps for Old."—The Renewable Electric Lamp Company, Limited, of Brunswick-place, City-road, N., announces that the equipment of the factory and the preparations for the supply of their patent renewable lamps of any candle power, from eight to fifty candles, are now completed, and the company are in a position to supply in large quantities. All old lamps, burnt out or having become dull, will be continuously exchanged for new ones at half the original cost, providing the glass bulbs are not broken. The present prices for the lamps are as follows: lamps for 100 to 110 volts, 8 c.p. to 16 c.p., first lamp 1s., afterwards 6d. each; lamps for 150 ditto, 1s. 3d. and 7½d.; and lamps for 200 to 230 ditto, 1s. 6d. and 9d.

Parliament.—In the House of Lords on Thursday week the Taunton Corporation, Coventry Corporation, Hastings Corporation, Alexandra Park, and Southport Corporation Bills were read a second time. The Sunderland Corporation, Great Northern Railway, Midland Railway, South-Eastern Metropolitan Tramways, and Portland Urban District Gas Bills were read the third time; and in the House of Commons the Dearne Valley Railway Bill, Glyncorrwg Urban District Council Gas Bill, London Sea Water Supply Bill, and Whitechapel and Bow Railway Bill were read a third time. The Workington Railways and Docks Bill was read a second time, and the London, Walthamstow, and Epping Forest Railway Bill was withdrawn. In the House of Lords on Friday the Durham (County of) Electric Power Supply Bill and the Lancashire Electric Power Bill were read a second time. The Midland Great Western Railway of Ireland Bill was read a third time and passed. In the House of Commons the Great Grimsby Street Tramways Bill and Mersey Railway Bill were read a third time. In the House of Lords on Monday the South Wales Electrical Power Distribution Bill and the Shannon Water and Electric Power Bill were read a second time, and the following Bills a third time: South Metropolitan Gas, London and South-Western Railway, Aberdeen Corporation Tramways, and Great Western Railway. In the House of Commons the London, Walthamstow, and Epping Forest Railway (Abandonment) Bill was read a third time. The Crystal Palace Company Bill was read a second time, and the Brompton and Piccadilly-circus Railway Bill was withdrawn. On Tuesday in the House of Lords the North Metropolitan Electric Power Supply Bill was read a second time, and the London and North-Western Railway and Blackpool, St. Annes, and Lytham Tramways Bills a third time. In the House of Commons the Lords' amendments to the Burnley Corporation Bill were agreed to, and the Lords' amendments to the Great Northern Railway Bill and the Midland Railway Bill were agreed to. The Rotherham Corporation and the Motherwell and Bellshill Railway Bills were read a third time. In the House of Commons on Wednesday the Lords' amendments to the South-Eastern Metropolitan Tramways Bill and the Portland Urban District Gas Bill were agreed to, and the Liverpool Overhead Railway Bill was read a third time.

Digitized by Google

Chichester.—At a meeting of the Town Council last Friday with respect to the provisional order for electric lighting owned by the Corporation, it was decided to apply to the Local Government Board for a further extension of two years in order that the Council might further consider the matter.

Salford.—We are informed that the new Corporation electric lighting station building is now on a very fair way to completion. The building is to contain plant to the extent of 10,000 h.p., and will supply current for both lighting and traction. The plant is expected to be ready to work next January.

Cupar Fife.—At a meeting of the Town Council last week a letter was read from the Electrical Supply Company intimating their intention to apply for a provisional order to supply electrical energy within the area of the burgh. The letter was remitted to the Lighting Committee to watch the course of procedure and report to the Council.

New Company.—The Brockie Pell Arc Lamp, Limited, has been registered with a capital of £80,000 in £1 shares. Its object is to adopt an agreement with the Brockie-Pell Arc Lamp, Limited (registered in 1896), and to carry on the business of manufacturers of and dealers in electric arc lamps, electric incandescent lamps, and electrical appliances, etc.

Edinburgh.—The Faculty of Advocates have decided to introduce the electric light into the advocates' library. The work is to be started at once, so that by the end of August the new illuminant will be in working order. The lighting of this fine library is entirely artificial, and electricity should much improve the present condition of things.

Ham.—At last week's meeting of the District Council letters were read from the Twickenham and Teddington Electric Supply Company and the Richmond (Surrey) Electric Lighting Company, giving notice of their intention to apply for provisional orders for electric lighting within the district of Ham. The letters were referred to the Highways Committee.

Monmouth.—Mr. E. A. Sandford Fawcett held an enquiry at the Shire Hall, Monmouth, last week respecting an application by the Corporation for power to borrow £28,000 as a supplementary loan for the purpose of completing the combined scheme for drainage and electric light in the borough. The money is required owing to the estimates being deficient.

Newbury.—The Corporation having received a notice from Edmundson's Electricity Corporation, Limited, on behalf of the Urban Electric Supply Company, Limited, of their intention to apply for a provisional order for electric lighting in the borough, have decided that the question of the electric lighting of the borough shall be considered by the whole Council.

Birmingham.—The City Council on Tuesday unanimously decided to acquire the site of the old hospital in Summer-lane, containing about 19,409 square yards, with the buildings thereon, and the canal basins, for the purpose of a central generating and distributing station, at a cost of £23,000, and to instruct the town clerk to have the property duly conveyed to the Corporation.

Our Cables.—It was announced in the House of Commons on Monday that the Departmental Committee which is to enquire into the working of the cable systems in the Empire will consist of Lord Balfour of Burleigh (chairman), representing the Board of Trade; Mr. Hanbury, financial secretary to the Treasury; and an under-secretary from the India and Colonial Offices and Admiralty.

Explosion.—An explosion occurred last week in a manhole at the corner of Queen-street and St. Vincent-place, Glasgow, used in connection with the Corporation electric light installation. Gas had collected in the manhole through a leakage in some of the mains, and it is supposed that the explosion was caused by an electric spark. The cover of the manhole was blown off, but no one was injured.

Willesden.—The scheme for electric lighting and traction designed by Mr. Ruthven Murray, which we mentioned in our issue of the 13th inst., was on Tuesday last unanimously adopted by the District Council. A loan of £143,624 is to be applied for immediately for the lighting works, while it is proposed to promote a Bill in Parliament to authorise the construction of the tramways at an expenditure of £53,247.

County of London and Brush Co.—The directors of the County of London and Brush Provincial Electric Lighting Company, Limited, have declared an interim dividend on the preference shares at the rate of 6 per cent. per annum for the half-year ended 30th ult., and an interim dividend on the ordinary shares for the same period at the rate of 4 per cent. per annum, both payable 15th prox. The transfer books and the register of members will be closed from 6th to 15th prox. inclusive.

Belfast.—At a meeting of the Electric Lighting Committee last week, the engineer submitted a report for the six months ended June 30, 1900, showing 351,641 units sold for half-year, as against 244,589 for the corresponding period of last year, equal to an increase of 44 per cent., the current sold for motor purposes being 15 per cent. of the total, or an increase of 85 per cent. over the motor current sold during the corresponding period of last year. This is probably due to the facilities which the committee gave for the hiring out of motors.

Change of Address.—We are informed by the Blackman Ventilating Company, Limited, that in consequence of the growth of their business they are now removing their central offices to their works at 443, Holloway-road, London, N., so as to concentrate management and staff for the quicker and more effective dispatch of business to the benefit of all concerned. Their engineer representatives for the London district, however, remain at and work from their City address, 63, Fore-street, E.C., but correspondence should be addressed to Holloway-road.

Croydon.—At last week's meeting of the Rural District Council the Coulsdon and Sanderstead Drainage Committee reported that the clerk had submitted a plan illustrating a proposal for the Corporation of Croydon to supply a portion of Sanderstead with electric light. The Corporation had not agreed to do it, but desired to ascertain the views of the District Council thereon. The Council said they had no objection to the Corporation carrying the electric light into the parish provided that they had power to take over the light if they wished to do so.

Poplar.—Last week the Vestry adopted a recommendation to place 15 arc light columns in the East India Dock-road, at an estimated cost of £636; that five other arc light columns be also placed in the parish, at a cost of £250; and that 25 prepayment meters be obtained on approval for three months, to be purchased if satisfactory. Mr. T. Roles, of Leicester, was also elected to the position of chief assistant in the generating department. It was also resolved to refer to the Works Committee the question of lighting the Board's offices and premises by electricity.

London County Council.—At the meeting of the London County Council on Tuesday it was agreed to lend the Battersea Vestry £14,000 for electric lighting purposes, and the Shoreditch Vestry £30,000 also for a similar purpose. In connection with the electric lighting of the Victoria-embankment the Highways Committee reported that it was necessary in connection with the electric light installation that a subway should be constructed between the generating station, which was in course of erection, and the Victoria-embankment subway. The offer of Mr. S. Kavanagh to do the work for £330 was accepted.

Bradford.—On Friday last Mr. G. W. Willcocks, one of the inspectors for the Local Government Board, held an enquiry into the application of the City Council for permission to borrow a sum of £56,000 for the purposes of the extension of the city electricity works. The amount asked for was £5,100 for extension of the buildings and the remainder for machinery, the principal items being: four water-tube boilers, with mechanical stokers, etc., brickwork, and foundations, £8,560; 2,600 h.p. engines and dynamos, £9,500; cooling towers, fans, pumps, and piping, £6,000; battery, £3,000; mains, £15,000; and meters, £4,500.

Chiswick.—The offer of the Aberystwyth and Chiswick Electricity Supply Corporation, Limited, to wire the new Council offices free of charge to the Council, the installation remaining the property of the Corporation for 10 years, after which it becomes the property of the Council, in consideration of the Council agreeing to take current from the corporation for 10 years at the uniform rate of 6½d. per unit, and undertaking not to use in the Council's offices any other form of illuminant during that period, has been accepted, subject to a proviso that in the event of the charge for electricity being made less than 6d. per unit to any other consumer in the district, the rate charged to the Council shall be similarly reduced.

Notting Hill Electric Lighting Co.—The directors have issued a circular to the shareholders intimating that the directors have decided that the method of raising the £100,000 new capital which will best serve the general interests of the Company, and at the same time afford due proportionate advantage to each class of shareholders, will be by the issue at present of £22,000 in 2,200 ordinary shares at £12 each to the existing shareholders in the following proportions: 1,100 to the holders of the 9,450 ordinary and ordinary preference shares, a proportion of about one for every nine, and 1,100 to the holders of the 550 founders' shares in the proportion of two for every one. An extraordinary meeting will be held in London on Aug. 1 to confirm the proposal.

Personal.—On the occasion of the departure of Mr. W. J. Leeming from the Blackburn Corporation electricity works for the purpose of taking up the position of assistant engineer to the electricity department of Buxton, he was presented with a travelling bag, combined silver sovereign case and matchbox, meerschaum pipe, etc., by the staff and workmen of the electricity department. Mr. Giles, the chief engineer, made the presentation, and hoped Mr. Leeming would be as successful in his new position as he had been at Blackburn.—Mr. Robert Hammond, M.I.C.E., M.I.E.E., etc., has been appointed electrical engineer to the Mansfield Corporation in connection with the establishment of the municipal electricity and refuse destructor undertakings.

Pwllheli.—The Town Council have received a letter from Messrs. Bennett and Ward-Thomas, of Manchester, offering to purchase the electric lighting provisional order obtained by the Corporation. The terms offered are to reimburse the Council the cost of order up to £400; the order to be transferred on a lease for 10, 20, 30, and 42 years; if the Council decide to take over the undertaking at the end of 10, 20, or 30 years, they must pay the company the total capital outlay, plus 2½ per cent. for 10 years on the same; the company are to charge per unit a price equivalent to gas at 1s. 9d. per 1,000ft. for public lighting, and a price equivalent to 3s. 6d. per 1,000ft. for private lighting. The lighting company would also undertake to work existing Corporation tramways at 50 per cent. of the revenue. The consideration of the matter was deferred for a week.

New Issue.—The Electric and General Investment Company, Limited, offers for subscription 19,370 5 per cent. cumulative preference shares of £5 each at par of the Dudley, Stourbridge, and District Electric Traction Company, Limited. This Company has an authorised share capital of £200,000, divided into 20,000 preference and 20,000 ordinary shares of £5 each, of which 630

Digitized by Google

preference and the whole of the ordinary shares have been issued. The Company owes the British Electric Traction Company under various construction contracts a balance of £62,750, and it is estimated that the further capital required to complete the works and discharge the remaining obligations under the various orders and contracts will be about £110,000. By the present issue of shares a capital of £96,850 will be provided, and the directors propose to raise the balance of capital when required by an issue of debentures.

Glasgow.—The accounts of the Glasgow Corporation electricity department for the year ended May 31 show that the revenue amounted to £59,762, of which £55,470 was from the sale of current per meter, and £4,201 from the watching and lighting department for lighting the streets. Compared with the previous year there is an increase of £15 620. The expenditure for the year was £38,181, leaving a balance of £21,580 to be carried to profit and loss account. In the previous year the balance was £12,607. The borrowing powers sanctioned by the Secretary for Scotland amounts to £700,000, and £628,500 has been borrowed. Of this amount £11,500 has been repaid, leaving borrowing powers to be executed to the amount of £60,000. The total amount of electricity generated last year was 3,401,731 Board of Trade units, against 2,619,019 in the previous year. The amount supplied to private consumers last year was 2,566,016 units, as against 1,885,902 units in the previous year, an increase of 680,114 units, while for public lamps the quantity supplied last year was 258,334, an increase of 30,200.

Fan Motors.—We have received from the Improved Electric Glow Lamp Company, Limited, of 103, Queen Victoria-street, London, a copy of their new catalogue of improved electric fan motors for continuous and alternating currents. Having regard to the tropical conditions of climate under which we have been labouring of late, this catalogue could scarcely have made a more opportune appearance. During such weather the efficient ventilation and distribution of air in rooms comes to be regarded rather as an urgent necessity than a luxury to be denied at slight inconvenience. Although electric fan motors have already found extensive application for the purposes of artificial ventilation, there is little doubt but that their employment might with advantage be largely extended. The present spell of hot weather should, however, do far more to stimulate this desired increase than any advice we could offer in these columns. Judging from the catalogue before us, the Improved Glow Lamp Company, Limited, seem to have devoted considerable attention to the requirements of the market. Numerous types of motor fans, each designated for a special purpose, are illustrated. To quote one paragraph: "For the convenience of our customers we stock two distinct types of desk and bracket fans, 'open-field' type and 'closed-field' swivel type. The swivel type fans embody the latest improvements, and can be adjusted to create a breeze in any direction, and are fitted with a neat handle for the convenience of removal. The open type gives the same results, but being more simple in construction can be sold at a lower price." What could be more inviting? It is almost as good as a visit to Blackpool to imagine that soothing breeze floating across as we sit at our desk in a stuffy office. Nor is such a breeze beyond the hope of those whose premises may not be connected up to a permanent source of electricity supply, since the firm in question also supply fan sets complete with batteries to run 150 hours without recharging. For the prices—in every way moderate—of an article of excellent reliability and finish, we would refer the reader to the catalogue in question.

HAMPSTEAD ELECTRICITY WORKS.

The accounts of the Vestry of St. John, Hampstead, electricity department have just been issued, from which it appears that the total expenditure on capital account up to March 25, 1900, amounted to £162,212. Abstracts of the revenue account and general balance-sheet are appended:

REVENUE ACCOUNT.

HASTINGS ELECTRICITY WORKS.

From the accounts of the borough of Hastings electricity works department just issued it appears that the total expenditure on capital account to Dec. 31, 1899, amounted to £78,916. We give herewith abstracts of the revenue account and general balance-sheet:

REVENUE ACCOUNT.

Dr.	Expenditure.	£ s. d.
Generation of Electricity.		
Coal* or other fuel	2,662 7 11	
Oil, waste, water, and engine-room stores	459 7 11	
Wages at generating stations	982 17 11	
Repairs and maintenance	491 18 3	
		4,596 12 0
Distribution of Electricity.		
Wages and other remuneration	21 2 11	
Repairs, maintenance, etc., of mains	31 7 7	
Repairs, maintenance, etc., of transformers, etc.	100 7 6	
Repairs, etc., at distributing stations	4 9 0	
		157 7 0
Rents, Rates, and Taxes.		
Rents payable	147 13 6	
Rates and taxes	302 16 5	
		450 9 11
Management Expenses.		
Salaries	423 2 6	
Salaries or commissions of collectors	153 8 0	
Stationery and printing	64 6 11	
General establishment charges	53 17 7	
		694 15 0
Law expenses		26 16 7
Insurances, etc.		184 11 3
Balance carried to net revenue account		5,379 9 2
		£11,490 0 11

* This amount includes £279. 5s. 9d. for town dues.

Cr. Income.	£ s. d.
Sale of current per meter	8,450 19 2
Sale under contracts	362 8 1
Public lighting, £2,650; less repairs and renewals, attendance, etc., £272. 12s.	2,377 8 0
Rental of meters and other apparatus	129 17 9
Sales and repairs	49 14 11
Rents receivable	119 13 0
	£11,490 0 11

	£85,531	12	6

PROVISIONAL PATENTS, 1900.

JULY 16.

12772. Improvements in and relating to arms and trolleys for overhead electrically-driven tramcars. James Townsley Pearson, St. James's Hall, Burnley.

JULY 17.

12827. Improvement in electrical switches. Ernest Edward Bartlett and John Edward Robinson, 10, St. George's-crescent, Liverpool.

12838. A "safety" carbon holder and carbon economiser for use in electric arc lamps. James William Ferrier, 7, Eythorne road, Ackerman-road, N. Brixton, London.

12842. Electric bell. Hans Edgar Friese, St. Mary's mansions, Paddington, London.

12846. Improvements in portable electrical safety lamps. Johann Glasmachers and Carl Müller, 221, Allecstrasse, Barmen, Germany. (Complete specification.)

12855. Improvements relating to the manufacture of bulbs for electric incandescent lamps. Charles Junge, 75, Chancery-lane, London. (The Oberlausitzer Glashüttenwerke Otto Hirsch, Germany.)

12874. Improvements in and relating to telephonic apparatus. Gregor Blanck, 323, High Holborn, London.

12876. An improved trolley for overhead electric traction. Edward Greenberry Johnson, Franklin Denise Palmer, and Carl Coenen, 53, Chancery-lane, London. (Complete specification.)

12893. Underground wires for transmitting electric energy. Tito Rosati, 52, Chancery-lane, London. (Complete specification.)

JULY 18.

12922. Improvements in electrical tramways and trains. Sir William Henry Preece, K.C.B., and Philip Cardew, 13, Queen Anne's-gate, Westminster, London.

12944. An improved electrical switch. Herbert Fitzroy Clayton, Thomas Bell, and Samuel Simpson Berry, 62, Market-street, Manchester.

12956. Improvements in voltameters for the electrolysis of the water system Garuti. Pompeo Garuti and Riccardo Pompili, 77, Colmore-row, Birmingham. (Complete specification.)

12971. Improvements in electric switches. David Robertson Bruce, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12972. Automatic booster in connection with a multiple-wire system. John Somerville Highfield, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

12973. An indicator for high electrical tensions. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.)

12977. Improved electric battery. Paul Emile Francken, 322, High Holborn, London.

12992. Improvements in or connected with electric traction. William James Davy, 40, Chancery-lane, London.

JULY 19.

13010. Improvements in high-voltage fuses. Walter Jamieson and the Scottish Wireless Electric Syndicate, Limited, 53, Bothwell-street, Glasgow.

13014. Improvements in and connected with fuses or cut-outs for high-voltage circuits. Hermann Oppenheimer, 55, Redcross-street, Barbican, London. (Actiengesellschaft Mix und Genest, Germany.)

13015. Improvements in and connected with insulated bases for switches. Hermann Oppenheimer, 55, Redcross-street, Barbican, London. (Actiengesellschaft Mix und Genest, Germany.)

13020. Apparatus for generating dynamical electricity by means of the direct influence of steam. Edmund van Haanen, 4, Corporation-street, Manchester.

13021. Improvements in electric ignition devices for internal-explosion engines. Edward Gardner, Thomas Harry Gardner, and Lawrence Gardner, 55, Market-street, Manchester.

13024. Improved means for starting and stopping electro-motors. August Edward Segnitz, 128, Colmore-row, Birmingham.

13031. An improvement in or connected with laminated electric switches. Albert Reame and Charles Wokes, 8 Quality-court, Chancery-lane, London.

13035. Improvements in or connected with apparatus for electrically igniting miners' safety lamps. Albert Edward Best, 33, Chancery-lane, London.

13036. Improvements in dynamo-electric machines and electric motors. Henry Francis Joel, 74, Windsor-road, Forest Gate, London.

13044. An improvement in electric railways in which transformers are carried on the train. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.) (Complete specification.

13048. Improvements in and relating to means for controlling the speed of electromotors. William Brewster Elliott and John William Eskholme, 1, Queen Victoria-street, London. (Complete specification.)

13049. Improvements in maximum demand electricity indicators. Ernest Schattner, 55, Chancery-lane, London.

JULY 20.

13081. Improvements in means for grinding and truing up dynamo commutators and the like. Percival John Purdy, 55, Market-street, Manchester.

13085. Improvements in the method of and means for sounding alarms on electric tram and motor cars. Alexandre Parietti and Aimé Regis Durante, 57, Barton-arcade, Manchester.

13095. Storage battery electrode. Roderick MacRae and Hector Campbell MacRae, 17, Basinghall-street, London (Complete specification.)

13102. Improvements in and relating to electrical conductors. William Alfred Phillips and Charles Eyre Kent, 323, High Holborn, London.

13103. A new or improved method and means for fire-proofing insulated wires and cables. William Alfred Phillips and Charles Eyre Kent, 323, High Holborn, London.

13104. Improvements in means for covering wires and cables. William Alfred Phillips and Charles Eyre Kent, 323, High Holborn, London.

13105. Improvements relating to the covering of electrical conductors. William Alfred Phillips and Charles Eyre Kent, 323, High Holborn, London.

13106. Improvements in safety devices for electric interlocking or block signalling apparatus. Frederick Thomas Hollins, Liverpool-street Station, London.

13125. Improvements in automatic cut-outs or combined cut-out and shunt switches for overhead trolley wires for electric traction, overhead electric cables, or the like. Robert Hacking, 111, Hatton-garden, London.

13134. Improvements in and relating to electric arc lamp. Allyn Ballard Walton, 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Dec. 21, 1899, being date of application in United States.) (Complete specification.)

13143. Improvements in telephonic signalling apparatus, applicable also to other purposes. The Thomson-Davis Telephone System, Limited, and Arthur Thomas Milnor Thomson, 22, Southampton-buildings, Chancery-lane, London.

JULY 21.

13134. The Eiland electric "railway" fog-signal. Alfred Brook, 10, Stratford-grove, Putney, London.

13195. Improvements in electrolytic apparatus for the production of caustic soda. George Henry Smith, 40, Chancery-lane, London.

13198. Improvements in electric traction. Baptistin Cruvellier, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on August 11.

1899.

14703. Carbon electrodes for arc lamps. Bremer,

Digitized by Google

12566. Arrangement and connections of the windings of dynamo machines. Abel. (Karmin.)

14572. System of electro dynamic propulsion. Rosenfeld, Zelenay, and Dulait.

14806. Counter or meter for electric lamps, motors, and other electric apparatus. Magini.

14878. Covering electrical and other wires and apparatus therefor. Colley.

15017. Electric accumulators or secondary batteries. Weymersch.

15207. Production of battery plates or other articles by electrolytic or chemical deposition of spongy metal. Neumann.

15418. Insulated electrical conductors or cables. Edmunds.

15904. Transformer boxes. Lawson, Dallas, and Goslin.

16091. Electrical apparatus suitable for lighting, cauterising, and other purposes. Richardson and Ramsbottom.

17877. Composition of or from which may be manufactured tubes for various purposes, tyres, and other articles requiring more or less flexibility, or for use as a non-conductor of electricity. Bestwick.

19446. Apparatus for periodically producing electric current by means of irregular motive power. Gehre.

20084. Method of and means for transmitting and receiving electric waves for the production of signals and for imparting motion to machines or apparatus. Cervera-Baviera.

20436. Electric arc lamps. Curwen.

22517. Electrical influence machines. Pidgeon.

22960. Electric insulating devices. Lake. (McCarthy.)

1900.

516. Points and switches of electric tramways and railways. Vesely.

4784. Magnet winding for continuous current machines and converters for effecting simultaneously a sparkless commutation and a pressure regulation. Déri.

7781. Apparatus for wireless telegraphy. Robinson. (Secret document under Sec. 44 of the Patents, etc., Act, 1883.)

7782. Transmitting and receiving switch for wireless telegraphy. Robinson. (Secret documents under Sec. 44 of the Patents, etc., Act, 1883.)

8344. Double pin plug and socket for electrical connections. Minn and Sun Electrical Company, Limited.

8704. Apparatus for facilitating the photometry of arc lamps and like sources of light. Carter.

8829. Safety lock with electrical door-opening device. Skopec and Herd.

8930. Phonograph record cylinders of celluloid, and the method of making the same. Petit.

8945. Electric motors particularly applicable for propelling boats. Boult. (Hatch.)

9413. Electric motor suspension on electrically-propelled vehicles, such as tramcars and the like. Gibbs.

9769. Manufacture of electric railways, rail bonds, and other electric couplings or terminals. McTighe.

10444. Electric incandescent lamps of the refractory conductor type. Patrouilleau.

11006. Secondary electric batteries. Lake. (Reuterdahl.)

11022. Electrical apparatus for adjusting tramrail points. Macaulay.

NOTES.

West Indian Cables.—We are glad to notice that the Jamaica-Colon cable of the West India and Panama Telegraph Company has been repaired, and messages for the Isthmus of Panama and all places in the United States of Colombia can now again be sent "*vid* Bermuda."

New Atlantic Cable.—The Commercial Cable Company's new cable from the Azores to New York, *vid* Nova Scotia, has been successfully laid, and was opened for business on Aug. 1. This line, which forms the company's fourth Atlantic cable, will connect at the Azores with the system of the Europe and Azores Telegraph Company.

Motorcar Accident.—We regret to note that the local manager for the National Telephone Company in the Cumberland and Westmoreland district, Mr. H. H. Eley, met with his death last week. The cause of death was an accident while trying a new motorcar. The deceased gentleman was well known and greatly liked in the district to which he was attached.

Institution of Electrical Engineers. — It is announced that permission has been kindly granted for the Institution of Electrical Engineers at their Paris meeting this month to hold a reception in the British Royal Pavilion in the Paris Exhibition from 5 to 7 p.m. on Wednesday, Aug. 22, and that arrangements for the reception are being made accordingly.

Books Received.—We have received from the Street Railway Publishing Company, of New York, a copy of a book by Mr. G. T. Hanchett, S.B., entitled "Modern Electric Railway Motors."—We have also received a copy of a small work entitled "The Application of Electric Motors to Machine Driving," by Mr. Andrew Stewart, A.I.E.E., published by Messrs. S. Rentell and Co., Limited, 2, Exeter-street, W.C.

Wedding. — A pretty wedding was solemnised last week at St. Saviour's Parish Church, St. Helier, Jersey, between Mr. Ellis John Hidden, district manager, National Telephone Company, Liverpool, and Miss Isabel May Laurens. Both Mr. and Mrs. E. J. Hidden have, we believe, been the recipients of a number of handsome presents, several of which have been forwarded by the staff of the National Telephone Company.

New Book.—For some time past, we are informed, Mr. W. Perren Maycock, M.I.E.E., has been engaged on a new work entitled "Electric Wiring Tables." This is now in the press, and is shortly to be published by Messrs. Whittaker and Co., of Paternoster-square, E.C. The book will be of small size for the waistcoat pocket, and the 30 or so tables therein, which are for the most part quite original, should be found of considerable use to electricians.

Electric Water-Cart.—A trial was made recently in Sydney of a new electric watering-cart, which has been constructed for the purpose of watering the tramway routes. The result of the trial was eminently satisfactory, and the car is expected to be of great practical use. The cart carries some 2,000 gallons of water, and can travel at a good rate of speed. By the use of this cart a surface of 10ft. from each side of the vehicle can be sprinkled with water.

Telephones.—We are informed that the Government offices in Germany have been testing the value of certain improvements in telephones, and the Bank of Darmstadt has now been entrusted with the floating of the novelties. It is claimed that the spoken message can be recorded in such fashion as to be reproducible as often as required; and that one wire under the new system can be used simultaneously by several persons. The sound is also strengthened, so as to make long-distance work easier, and a message can be transmitted simultaneously to various points.

Cape-to-Cairo Telegraphs. — The Berlin correspondent of the *Daily Mail* informs us that the trans-African telegraph line, which is being constructed by Mr. Rhodes, was to reach Kassanga, which is in German territory, by the end of July. The information which we receive as to the progress of this line is not very much, but such as it is, it always points to the fact that great efforts are being made to complete this important line within a comparatively short space of time.

Channel Steamers and Wireless Telegraphy.—We have stated before in our columns that a system of wireless telegraphy was to be installed on the South-Eastern and Chatham and Dover Railway Companies' boats between Dover and Calais. This scheme, however, seems doomed to failure, owing to the obstruction of the Post Office authorities. The installation was not intended to have in any way taken the place of the Post Office telegraphs in the conveying of messages, but would have been used by the railway companies entirely on their own business.

The Pacific Cable.—According to the Ottawa correspondent of the *Times*, there is another outburst of indignant protest in the Canadian Press over the inexplicable delay in connection with the Pacific cable tenders. Canadians cannot understand why the manufacturing firms should have been given a month's notice when a week would have sufficed, unless it was so arranged in order that the tenders should be received at a date (Aug. 14) when London is deserted, and the members of Parliament interested in the question are away on their holidays, thus securing further delay in the interests of the Eastern Extension Company.

Our Volunteers.—At the meeting of Messrs. Crompton and Co., which was held last Monday, one of the shareholders asked for information as to the members of the firm who were away in South Africa. The chairman himself could not give much new information on this point, but stated that the corps had been showing itself of great use. Another of the shareholders, however, gave the required information, and stated that, from a conversation with a member of Mr. R. E. B. Crompton's family on the previous day, he learnt that Mr. Crompton was still in Pretoria in connection with the organisation of the construction train.

To Brighton by Motor.—From the *Daily Mail* we gather that a new electric automobile — a voiturette to carry two persons—built by the National Motor Carriage Syndicate, has made a successful run from London to Brighton on one charge of electricity. The total distance covered was 53 miles, the run being made at an average speed of 10 miles an hour, and varying from 15 miles per hour on the level or slight inclines to six miles per hour going up the hills. The automobile is of English construction, the carriage being the work of Mulliner, of Northampton, while the electrical and mechanical part is by Messrs. Joel and Potter, of London.

A Novel Mission.—According to the *Daily Mail*, Mr. Charles T. Yerkes, the American street railway magnate, has arrived in England from New York. The reason of the visit of Mr. Yerkes is to negotiate with the County Council for the building of electric tramways in London. It is stated that it was at first Mr. Yerkes's intention to bid for the control of London's street tramways; but as London is rather an expensive place for little experiments of this kind, he now proposes to confine himself to the mere task

Digitized by Google

of building the lines if he can obtain the contract. Mr. Yerkes is stated to own the controlling interest in most of the principal street railways in the United States.

Royal Telephones.—The telephone evidently finds favour in Royal eyes, as we learn that a telephone has been established between Windsor Castle and Cumberland Lodge, which is situated some distance away in the Windsor Park. In former times it was usual to send a mounted courier with messages from the Queen to Prince and Princess Christian, but under the new order of things this messenger has been found to be needless. The telephone had previous to this been installed between Windsor and Buckingham Palace, Marlborough House, and the principal Government buildings.

Electricity in Lahore.—We are glad to note that yet another important town in India has seen the advantage to be derived from using electricity as an illuminant. We have from time to time during the past few years noted the fact of one or other Indian town installing electricity, and in most of them it has proved quite a success. The latest convert to this system of lighting is Lahore. In this town the municipal authority have decided to instal electric light, but as a makeshift, until the electrical scheme is finished, they are about to proceed with the lighting of the main road with acetylene. The electrical scheme is, we understand, expected to be realised in about two years' time.

Russian Electric Tramways.—The tramway lines in Moscow, we learn, are about to be extended, and will reach a total of 84 miles. It has been decided at the same time to change the present system of horse traction for the electric trolley system over the greater part of the system, while the remainder will be operated on the surface-contact system and by accumulators. The cars will travel at a speed of 12½ miles an hour. The time limit allowed for the conversion of the lines from horse to electric traction is four years. At Riga, also, the Municipal Council have decided to construct a system of electric tramways, and have obtained powers to borrow £160,000 for this purpose.

Indian Electric Tramways.—We notice in our contemporary *Indian Engineering* the announcement that proposals having been made for making an electric tramway between Hyderabad and Secunderabad, a scheme has been formulated which combines a service of electric lighting and all the other advantages derivable from electrical power supply installation. The scheme is, however, at present only under consideration, and its fate is very uncertain. However, the mere fact of the necessity for electric traction having been recognised in this important part of our Indian Empire should be very encouraging to the makers and designers of apparatus for this kind of work.

The Shah in Paris.—The visit of the Shah of Persia to Paris has, one would judge from the accounts of his doings in that city, furnished him with ample food for thought during the next few months. Thus his Majesty has been surprised and pleased with the horseless vehicle as used in France. He is, we gather, intending to purchase one or more to take back to Persia with him, and for this purpose has had several makes brought up for inspection, but it is supposed that he will inspect the exhibition at Vincennes before taking the final plunge. His method of inspection and trial is rather dangerous, it would seem, as it consists of rushing up and down the Bois de Boulogne at breakneck speed.

A New Transatlantic Cable.—It is stated that on Wednesday last the first German-American cable was opened for the transmission of direct messages between Germany and the United States. The line stretches from Borkum to Fayal, one of the Azores, and thence to New York, and is 4,366 knots in length. The cable was laid by a British company, but was taken over by the German Atlantic Telegraph Company on payment of a sum of nearly two millions sterling. The German Government will, we understand, subsidise the new undertaking by an annual payment of £140,000 for 40 years on condition that another cable is laid should the Government consider this advisable. The price per word to New York will be just over 1s.

Electricity in Germany.—From statistics recently published in Germany, we gather that the electrical industry in that country is progressing at a very fast rate. Thus in the German Empire, it is stated, more towns are supplied with electricity than with gas, and electrical railways are becoming more in demand. There is, however, great difficulty in Prussia in getting the authorities to allow a charter to be granted to a private company for running long electric lines. The reason for this is said to be that the authorities look to the railways as one of their chief sources of revenue, and in consequence wish to have practically entire control of them. It has, however, been stated that experiments are being tried in high-speed electric traction, and we hope that some good results will follow.

The Central London Railway.—The opening of this line to the public last Monday seems to have been rather successful as a start. There was but one slight mishap, owing, we believe, to a brake getting out of order; but, taken as a whole, the railway performed its first day's public service in a very creditable manner. The effect of the opening of the line on the other underground railways has yet to be seen, but as far as one can judge from personal observation the new railway has drawn away a considerable number of passengers from the older ones. A great many, no doubt, may return to the latter in time, probably only travelling on the new line as a novelty. There can be no doubt, however, but that this new facility for reaching the City will to some extent affect the receipts of the other companies.

Electricity on German Warships.—Electricity is finding extensive employment both for lighting and power purposes upon some of the newer ships of the German navy. In proof of this it will suffice to instance the "Fürst Bismark," which possesses, perhaps, the largest electrical installation of any war vessel in the world. The vessel in question, it may be mentioned, is an armoured cruiser displacing some 10,608 tons. Her electrical equipment comprises five compound-wound steam dynamos, each having an output of 590 amperes at a terminal potential of 110 volts. The electromotors on board number 43, while five 40,000-c.p. searchlights are installed, besides about 1,000 incandescent lamps. In addition to the interior lighting of the ship, and for the telegraph, signalling, and searchlight apparatus, etc., electrical energy serves for working the numerous ventilators, ammunition hoists, gun turrets, steering gear, and boat hoists.

Spanish Overhead Lines.—It is gratifying to learn that the negotiations which for some time past have been taking place between the American Thomson-Houston Company and the municipal authorities at Valencia have terminated successfully. The agreement provides that the company shall equip the trams electrically, and pay a yearly rental of about £4,600 while the receipts are below £32,000, after which the lessors receive 5 per cent. more, and on reaching £40,000, 10 per cent. The whole electric plant is to be the property of the lessors, who are also to possess the right to devote to public lighting any surplus electricity generated. Electric machinery and plant is to be supplied by the American General Electric Company, but the cars will be constructed in Spain, where a few

Digitized by Google

factories recently established turn out fairly good and cheap work, though in elegance, solidity, and comfort the cars are not equal to those manufactured in the American and English shops.

Electrical Potatoes.—The question was asked in the House of Commons recently by Mr. Austin if the Vice-President of the Department of Agriculture could state what were the reasons of the enquiry promised regarding certain experiments made by Mr. O'Sullivan, of Athea, county Limerick, in the improvement of the potato crop by the introduction of electricity through lightning conductors distributed through the crops by means of wires, by which it was stated that an increase of 80 per cent. was shown. In reply, Mr. Plunkett said a departmental inspector had visited Athea to make enquiry on this subject, and reported that the experiments conducted last year by Mr. O'Sullivan to test the influence of electricity on the growth of potatoes were too limited in extent to warrant conclusive deductions. Similar experiments on a large scale were, it was stated, in progress this year under Mr. O'Sullivan's direction, and would be watched with interest by the Department.

H_2O.—The remarks of a correspondent in a contemporary upon the "all-penetrativity" of water have suggested the following lines:

The like hath Wilfred Lawson's mouth enjoyed;
It also hath a pleasant use with soap;
And in the boiler-house is well employed.
But, Allah! how the mains it hath annoyed!

It makes its path no matter where nor how,
It takes the insulation for its prey;
It shorts the main (by devil's aid, I vow)
That hath been laid with pains and care enow.

And when, by use of iron and plumbed joints,
The hand of man hath baffled it to-day—
Through the still air a passage it appoints,
It changes body twice, and then anoints.

It pays no heed to earthly rules or laws;
At gravity its nose and thumb are met.
It is its own effect without a cause.
(And very keen it is in finding flaws.)

* * * * *

'Twould seem as though the play was tit-for-tat:
Since in the sky the force the element rules,
And splits the liquid clouds. To balance that
The water strives, remembering Ararat.—J. H. C. B.

Liverpool Tramways.—The progress of the electric tramways in Liverpool is very interesting, as the conversion from horse to electric traction is in that town carried on at a rate which is unprecedented. Thus the first part of the system, which is worked by means of the overhead trolley, was opened in November, 1898. This experimental line having proved a great success, the City Council decided to equip all their lines electrically, and last year some 30 miles of track was reconstructed. About 80 miles have now been finished, and the engineers hope to finish the system within the year. During the past few months the rate of construction has been about two miles per week, a rate which, it is stated, has never before been reached. The accommodation for passengers with the electric cars will be ample, and the fares appear to be also very low, a penny fare covering from 2 to 2½ miles. The fares are to be even further cheapened, however. It is hoped that in another year a uniform 1d. fare will be established, when passengers will be able to travel nearly 8½ miles for 1d.

Electric Cars in New York.—We gather from our contemporary, the *Electrical Review* of New York, that an attempt is once more to be made to introduce storage battery cars on the streets of New York. Our contemporary remarks concerning the trial made with such cars 12 years ago in New York, that failure was at that time practically a certainty, and that it was surprising how near success the experiment came. In view, however, of the high state of perfection to which accumulators, motors, and controlling gear have been brought at the present date, it is stated that on reasonably level roads the accumulator car should prove a great success. With respect to this revival in New York, we think it would be a rather good thing if in London a similar revival were to take place, and, not discouraged by the non-success of the London Electric Cab Company, another company with a fair amount of capital were to take upon themselves to place really good and serviceable accumulator cars on London's streets. The causes which led to the downfall of the first company were in a very large measure preventable, and, with capable engineers and a good Board of directors, such a company could not fail to succeed.

The Earth's Magnetism.—In the course of a contribution to the *Elektrotechnishe Zeitschrift* upon the subject of the generation of thermo-electric currents, Herr von H. Egg-Sieberg makes some interesting deductions concerning the earth's magnetism. From the experiments which he describes, the author concludes that the magnetic influence exerted by the earth at any point must be strongest when the maximum fall of temperature occurs at that point. This assumption would explain the daily fluctuations of the earth's magnetic influence, and at the same time the circumstance that these daily fluctuations are greatest in the summer and smallest in winter. Assuming the aurora to be caused by the discharge of atmospheric electricity into the earth's surface, it is probable, continues the author, that the local direction of the earth's current is thereby so modified that the lines of force vary in the manner observed upon the appearance of the phenomena in question. Finally, it is conceivable to the author that the earth's current may undergo an appreciable change through momentarily great changes of the earth's surface caused by earthquakes and volcanic eruptions, disturbances of the magnetic needle such as have been observed on such occasions being thereby entailed.

The China Troubles.—As happened when Ladysmith, Kimberley, and Mafeking were besieged, certain papers are exclaiming, "Why was not wireless telegraphy installed at Pekin?" It would, of course, be a great relief to the various countries if communication by this means could be employed, but up to the present wireless telegraphy seems to require a lot more developing before it could be of use between Pekin and the nearest station to which the allies could approach it. In addition to this, it might be pointed out that it would take a considerable amount of time and money to instal wireless telegraphy in every town or village which might suddenly be surrounded by a hostile force. It is surprising that no one seems to have made the same remark about Coomassie, in which there was also a British garrison. It might, perhaps, be well, however, if, while there is any prospect of other important towns in China being attacked, an installation of this telegraphy were placed in them. Another important thing in connection with the Chinese rising is the need for a good cable service between that country and Europe and the United States. The present service would be anything but adequate if called upon to bear the strain of a large number of war cables, and would probably break down at most important times.

New South Wales Electrical Association.—A general meeting of this association was held recently, when an interesting paper on "The Electrical Industry in America and Great Britain" was read by Mr. J. R.

Digitized by Google

Bainton, M.I.E.E. The lecturer's remarks were confined to the appearance of the industry between October, 1899, and January, 1900. A noticeable and important feature which he noticed was the greatly increasing use of polyphase transmission schemes, with rotary converters for long-distance lines. He referred to a novel departure in traction in London—viz., the method of operating the City and South London Railway on a three-wire system, with 1,000 volts on the outer wires. The conduit systems of New York and Washington were, in his opinion, types of the very highest class of electrical street railways in the world. Apart from its application to tramway work, polyphase transmission was largely on the increase. Incidentally, the lecturer compared Sydney with San Francisco, which, with a population of 300,000, possessed 250 miles of tramway, as against 50 in the former town. He also dealt with various other matters which the electrical industry affected. In conclusion, Mr. Bainton said he was very much disappointed with the appearance of the electrical industry in England as compared with America.

The Metropolitan Railway.—We are glad to see that a success has been made of the electrical train running between Earl's Court and Kensington High-street. The success must be even greater than the chairman stated at the meeting, as the train is run at a time when the passengers are likely to be few. The chairman's statement as to the employment of electrical traction on the whole of the Inner Circle line is very gratifying. Thus he stated that a committee consisting of three members from each of the Boards of the Metropolitan and District Companies has been appointed to consider the question of applying electric traction to the working of the Inner Circle, and it has been agreed between the companies to invite eminent electrical traction firms to submit plans and specifications with detailed estimates and tenders for the necessary installation. In addition to the good results obtained from the experimental train in London, the experiments in the direction of electric traction made by the companies at Wembley Park were also stated to have been eminently satisfactory. The two companies recognise that those best informed as to the systems applicable for certain conditions are those who are engaged in building such lines, and they are doing a wise thing in asking some of the most eminent electrical firms to submit their views as to the best method or system to adopt for the working of the Circle.

House Cooling.—A great deal of ingenuity has been applied to the perfecting of methods of heating dwelling-houses in the United States. For relief from the extremes of hot weather, however, very little has been done, and there is practically no feasible method of cooling small houses. Of course, large places of entertainment are provided with apparatus for this purpose, but private houses do not offer such an easy problem from an economical standpoint. The matter has been given somewhat more attention abroad, and an interesting paper was presented at a recent meeting of the Heating and Ventilating Congress in Munich by Dr. Bruckner, who explained that the most feasible means of cooling were through ammonia or carbonic acid, which took up heat as they expanded. Dr. Bruckner described, however, one house in Germany which had a regular system of cooling operated by a 3-h.p. electric motor. The house was in Frankfort, and the system has been working for five years, salt water being cooled and carried through pipes in the ceilings of the dwelling-rooms, the ceilings being perforated with narrow slits, through which the air as it was cooled fell into the room. Being an electric motor, it was easily handled, and, in fact, the only attention given to it was by the woman cook. It is estimated that the entire outfit cost about £1,000, and the power for running it was estimated at about £15 a year. The smaller charges incidental to the machinery were not included.

Sydney Tramways.—We mentioned in a recent issue some facts as to the progress of electric tramways and railways in Australia. We again notice that in Sydney electric tramways seem to be becoming more and more appreciated. Thus in the New South Wales Railway Budget we see it mentioned that representations have been made to the Railway Commissioners urging the early conversion of the Balmain line to electrical traction, and also the extension of the line from the present terminus to the foot of Darling-street. The Commissioners, in reply, stated that they hoped to make this alteration by the end of the present year. The construction of the electric tramway from the shore of Neutral Bay to Military-road is now about completed, and was to have been opened on June 25. Trials made previous to the above-mentioned date were very satisfactory, the overhead system working extremely well. The Railway Commissioners are also stated to have recently imported a tramway motor equipment fitted with electric brakes, and experiments with this are said to have given satisfactory results. The electric tramway car-shed at Newtown is approaching completion. It is of considerable dimensions, having been designed to hold as many as 120 cars of the bogie combination type. In connection with the conversion of the steam trams to electrical working, it is also understood that similar sheds will be necessary at Randwick and elsewhere.

The Incandescent Electric Lamp.—We notice in the *Electrical Review* of New York an article on Edison incandescent lamps. The *raison d'être* of the article is that 20 years ago Mr. Edison first gave a public exhibition of his lamp, and started the first factory for its manufacture. It is pointed out as an interesting fact that while the lamp at the present time contains the same elements as when first manufactured, yet each of the elements have been so changed and developed that the present lamp is entirely different to that of 1880. The lamps were at first naturally more expensive than now, and one is not surprised to find that the cost was five times as great. In spite of this, however, the profit per lamp is now much greater than at first. Amongst the points of difference noted by the article in comparing the old and new lamp is the shape, which depended on the skill of the operator, but is now moulded. The bamboo filament of the old lamp has given place to a much neater and more useful one with a carbon coating. The amount of platinum used has been greatly reduced, and the base of the lamp considerably improved. The vacuum in the lamp, although only taking one minute to produce, is much more perfect than that of the early days, when the time taken was some hours. While dealing with these lamps, it is interesting to note that the Edison lamp factory of the General Electric Company in America turns out 55,000 lamps per day, or nearly 16,000,000 per annum.

Electrical Fires.—An attempt has recently been made by a fire insurance company in France to recover damages from an electric lighting company with respect to a fire in a consumer's premises said to be due to electricity. The company pleaded that the work was badly done, and hence that the electric lighting company was liable. The case was tried before the Court at Narbonne, and the verdict given in favour of the electric lighting company. We have seldom heard of a more ingenious attempt of an insurance company to avoid meeting its obligations. These companies have to insure their clients against damage, and before doing so must consider the risks undertaken. It is when examining these risks that they have the right to

Digitized by Google

insist on modifications, either in building construction or in the detailed equipment of the same, and the company always fix the amount of the premium in accordance with the probability of a fire occurring. Unless afterwards they can prove that the owner or the electric lighting company, for instance, has wilfully caused the fire, the insurance company has to bear the whole cost of the damage done. If this were not so, it would obviously be better for the private individual to take the risk himself, and recover from gas and electric light companies in the event of a fire occurring. In fact, we do not remember seeing anywhere a claim made with less reason, as the electric lighting companies have, as a rule, no right to inspect and condemn electric light work on the consumer's premises.

Institution of Junior Engineers.—On Friday last a number of the members of this Institution availed themselves of the opportunity afforded by Mr. Basil Mott for visiting the generating station of the Central London Railway, at Shepherd's Bush, under the guidance of Mr. Beaumont Pontifex. The electric locomotive shed was first seen, and two specially-designed steam locomotives capable of working in the tunnels were also shown. In the boiler-house were seen 16 Babcock and Wilcox boilers in eight pairs fitted with Vicar's mechanical stokers. Hunt's coal conveyor was seen in operation, taking the coal from the storage bunkers, which are of 1,000 tons capacity. Four sets of Green's economisers are fitted, and four Barnard-Wheeler cooling towers. Although the line was not open to the public, trains were running and had been for some days previously under ordinary working conditions, to accustom the employés to their duties. In the engine-house are six Reynolds-Corliss compound condensing engines supplied by the Edward P. Allis Company, each engine being of 1,300 i.h.p., and running at 94 revolutions per minute. The engines are coupled direct to three-phase generators of 850 kw. capacity, 5,000 volts pressure, and 25 cycles. At the conclusion of the visit, the party travelled over the line from Shepherd's Bush to the Bank and back.—The Institution of Junior Engineers proposes this year to hold its summer meeting at Newcastle-upon-Tyne from Aug. 13 to Aug. 18, the president being the Hon. Charles A. Parsons, F.R.S.

Sparking at Alternating-Current Switches.—An article by Herr von Ludwig Kallir, abstracted in the *Elektrotechnische Zeitschrift*, tells us something about the sparking phenomena which occur between the two metallic terminals of a switch upon pulling it out of an alternating-current circuit. The sparking which occurs upon breaking a circuit fed with alternating currents is notably of shorter duration than that which takes place when breaking a continuous-current circuit. According to Arons, the formation of an alternating-current arc between two metallic electrodes is impossible, even if the electrodes be slowly drawn asunder and previously heated. In order to learn more about the sparking phenomena in question, the author photographed the sparks on a plate moving at a known velocity. The contacts of the switch employed were of platinum or copper and mercury respectively, the cup containing the mercury being lowered at a known speed. The experiments showed that under ordinary conditions the spark is maintained only for a half period, but under conditions particularly favourable to sparking (high E.M.F., large current, slow breaking of the circuit) the spark continued for more than a half period, in many cases for nine to eleven periods. The longer maintained spark appears on the negative as a uni-directed current wave; it is not an alternating spark, but an intermittent direct-current spark. The spark, however, behaved otherwise in a vacuum, where it occurred at half periods in both directions. This may be attributed, the author thinks, either to the absence of oxygen or to the decreased pressure.

Tramway Troubles at Dudley.—A most extraordinary state of affairs has just occurred at Dudley. In connection with the reconstruction of the local tramways, the Dudley Corporation have an agreement with the British Electric Traction Company to take over at valuation in about four years' time the whole of the lines within the borough. One clause in the agreement provides that the lines shall be constructed and equipped to the satisfaction of the borough surveyor, and this caused all the trouble. On Saturday last work was proceeding on the Sedgley line of tramways when the surveyor discovered that, instead of laying the cables in earthenware conduits and setting them in pitch, the tramway company's workmen were drawing the cables through pipes. The surveyor protested, but the company's foreman still continued the work, and relations then became strained between the various officials, and a gang of Corporation workmen were set to fill up the trench which the tramway men had excavated, and as fast as the tramway men pushed forward their cutting the Corporation employés filled it up. Naturally, high words passed between the two sets of workmen, and threats were indulged in. This continued throughout the evening and into the night, but actual blows were prevented by the police. It is stated that at the earliest possible opportunity an injunction is to be applied for by the Corporation, but surely other methods than the one adopted could have been employed to get over the difficulty. The whole action seems to have been quite childish, and one would have thought beneath the dignity of the officials of a corporation and of a large tramway company.

Wireless Telegraphy.—We notice that further experiments in wireless telegraphy are about to be made between Ilfracombe and the Mumbles, across the Bristol Channel, a distance of about 25 miles. For this purpose a pole 115ft. high has been erected at Ilfracombe, and a similar pole has been fixed at the Mumbles. The system designed by Sir W. H. Preece, before that of Marconi, and improved recently, is to be tried. In commenting on this fact, the *Western Morning News* considers it remarkable that the Admiralty have made no wireless telegraphy installations on the coast for communicating with the battleships at sea during the manœuvres, all that has been done being to signal to passing ships by semaphore and flagstaffs. These are visible only a few miles at sea, and in foggy weather are of little use. In such weather guns are used, and loud sirens giving long and short blasts representing the dots and dashes of the Morse alphabet. Four ships of the "A" Fleet—viz., the "Majestic," the "Diadem," the "Blake," and the "Edgar"—are fitted with the wireless telegraphy apparatus designed by Captain H. B. Jackson, R.N., which is similar in some respects to that of Marconi. The navy this year has abandoned Marconi's system, which was successfully worked by the inventor last year between two battleships 65 miles apart, and has fallen back upon the earlier system invented by Captain Jackson. So far this system has not been worked a greater distance than 25 miles, and then somewhat imperfectly, the dots and dashes having a tendency to run into one another. That the Admiralty is fully alive to the importance of the subject is obvious from the fact that a series of experiments has recently been carried on more or less successfully on board 32 vessels of the navy, at a cost of £6,400, the difference between this sum and £9,500 recently voted in the navy estimates for wireless telegraphy being charged by the company holding the royalty.

ELECTRIC LIGHTING AT ROTHESAY.

The Royal burgh of Rothesay is the most important of the many beautiful coast resorts for which the estuary of the Clyde is justly famous. It occupies a position which for natural beauty, and the various attributes that go to make up a desirable holiday haunt, it would be hard to beat.

Rothesay is to Glasgow and the West of Scotland what Brighton is to London—indeed, one often hears it described as "the Brighton of Scotland," or, again, as "the Madeira of Scotland." Though Rothesay is compared to Brighton and Madeira, this does not in the least imply that Scotchmen consider either of these places to be a patch on their favourite holiday resort, as a born Scot would not consider Brighton to be "in the same street" as Rothesay, while Maderia would only come in as a bad second. Situated on a beautiful bay in the island of Bute, and surrounded by the lochs and mountains of Argyleshire, the town presents on a fine summer day an appearance which pleases the eye of the tourist, even though he has seen all the most beautiful seaside resorts both at home and in other lands.

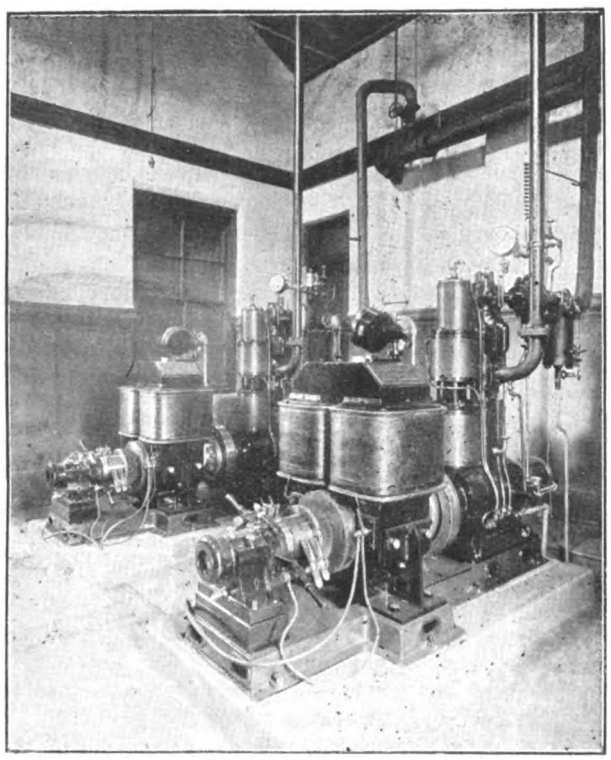

FIG. 1.—Interior of Engine and Dynamo Room, Rothesay.

However, enough has been said with regard to the natural beauties of the town, and now we come to the latest acquisition which has been obtained to supplement these natural attractions—namely, the installation of the electric light. In the year 1897 it was decided to obtain a report and preliminary estimate with a view to applying for a provisional order, should the Town Council consider the proposed outlays as likely to result in the benefiting of the community. At the time of the inception of the scheme Rothesay was fortunate in having for its provost the Marquis of Bute, who, having an extensive private installation at his beautiful residence, Mountstuart, near Rothesay, was in a position to appreciate the great advantages which would accrue to the burgh from the introduction of electric light. A committee of the Council was formed to deal with the question of electric lighting, having for chairman ex-Provost Milloy, who from the time that the matter first came up to the completion of the work has spared no trouble to insure the success of the scheme. The Council employed as their consulting engineer Mr. T. Crichton Fulton, of Glasgow, and a provisional order having been applied for and granted in November, 1898, Mr. Fulton was instructed to prepare a report on the most suitable scheme for the town. Several schemes were submitted, and the one that was chosen was for a continuous-current supply for public and private lighting on the three-wire system, with 500 volts between the outers.

We may here digress to point out that Rothesay is not in the happy position of having an "all-the-year-round" season like most of the English watering places, about four months being the extent of the season proper. The only establishments which are at all extensively patronised in the winter are the two hydropathics, the larger of which has a private electric light installation. For this reason, principally, it was not thought advisable at the commencement of the undertaking to put down plant for private consumers, as owing to the short hours of lighting during the "season" the demand would have been very small. In spite

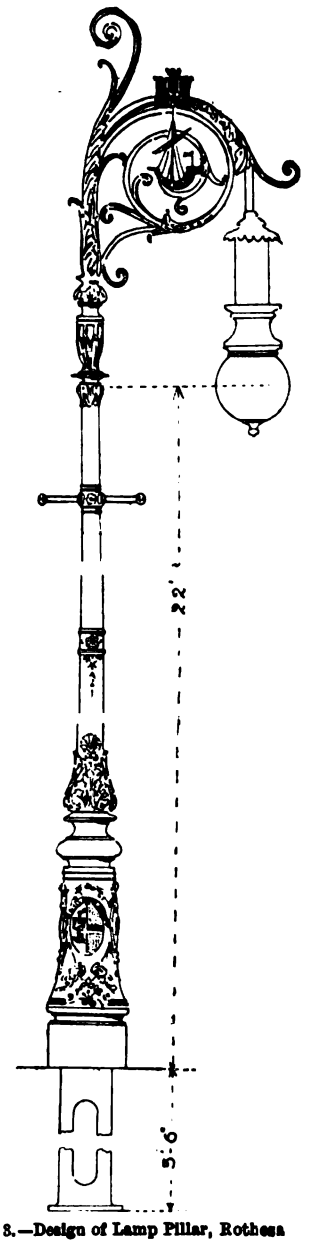

FIG. 3.—Design of Lamp Pillar, Rothesa

of this fact, however, there should be no difficulty in running plant for private lighting at a profit after a reasonable time has been allowed to elapse for the new illuminant to "catch on" with the public.

The Council having decided to proceed with the public lighting of the burgh, the work was put out to public tender. The tender accepted by the Council was that of Messrs. Lowdon Bros. and Co., of Temple Electric Works, Dundee, whose offer for the work was about £2,500, exclusive of trenching and foundation work. The total cost of the work, including all extras and trenching, came to about £3,000. The plant as at present running is arranged so as to fit in with the extended scheme, with the minimum amount of expense and alteration when the extensions have to be made. The site of the generating station is at the new Corporation gasworks, which are situated barely half a mile from the central part of the town.

The station is a substantial brick-built house about 80ft

Digitized by Google

square, situated only about 10ft. or thereabouts from the boilers. The main steam-pipe is 7in. in diameter, of welded steel, with flanges screwed and riveted, and jointed with corrugated brass jointing rings. The branch steam and exhaust pipes are of wrought iron, with screwed connections. All the piping under pressure is lagged with "magnesian sectional" covering. The steam-pipe system is drained into a Sturtevant steam-trap, and is supported by means of slings from the roof and from wall brackets.

The boilers are two in number, and have been working now for about four years, being put down when the new gasworks were erected. They are not of very suitable type for an electric supply station, as they are single-flued, burning slack with Meldrum's system of forced draught, but for present demands they answer the purpose fairly well. They supply, at a reduced pressure, the gasmaking apparatus and pumps, while the electric lighting engines are supplied with steam at the full pressure of 150lb. per square inch. The boilers are fed by means of two Worthington feed pumps, which were substituted for the injectors formerly in use. These pumps are of the vertical Admiralty pattern, and each is capable of delivering 1,500 gallons of water per hour. It is intended to put down additional boiler power when the station is extended.

There are two 20-b.h.p. compound high-speed non-condensing engines, made by Messrs. Alley and McLellan, of Glasgow. They have each two cranks, four cylinders, two high-pressure 4½in. in diameter, and two low-pressure 7in. in diameter, working tandem, one pair on each of the cranks. The normal speed is 575 revolutions per minute. The governor is mounted directly on the end of the shaft, and actuates a special throttle regulating valve. The engines are guaranted to work with a steam consumption of not more than 24lb., 25lb., and 26lb. of dry steam at 145lb. pressure at full, three-quarters, and half loads respectively. The engines are coupled direct to two Parker dynamos, each capable of giving 47 amperes at 280 volts, and of being run up to 360 volts for battery charging. These are intended to act as balancers when private supply is commenced, but in the meantime they are coupled in series and supply the arc lighting circuits with current at 500 volts. Fig. 1 shows the interior of the engine and dynamo room.

The switchboard is of Messrs. Lowdon Bros. and Co.'s standard type, with fuses having a clear break of 4in., to deal with 500 volts. A Kelvin standard pattern voltmeter reading up to 600 volts and a Kelvin ammeter are mounted on the board.

The mains from the station to the centre of the town are two three-core $^7/_{18}$ S.W.G. cables, each with the three cores connected up in parallel to form a $^{21}/_{18}$ cable. When private consumers are to be supplied, the arc lamps will be fed from the distributing mains, and what are at present supplying the current for them will be used as two three-core pilot wires for two feeding points on the system. This arrangement has done away with the necessity of laying down special arc lamp mains from the station to the town, which would have been subsequently of no use. About a mile of three-core $^7/_{18}$ cable has been laid, and about 5½ miles of $^7/_{17}$ single-core cable for the arc circuits. The cables are all of the British Insulated Wire Company's make, lead-covered, armoured with steel tape, and served over all with impregnated jute yarn. They are laid directly in the ground (for the most part under the footpaths) with rough deal boards laid over them as a precaution against damage from street excavation work. Lead-covered cable without armouring, but drawn into 3in. cast-iron piping, is used on the pier. At the height of the season it is no uncommon thing for 10 or even 12 pleasure steamers to be at the pier at one time. Of course this has the effect of so crowding the pier, as to render it impossible to break up the surface for cable repairs without causing great inconvenience to the public. Hence the use of cables drawn into iron piping for this portion of the work. A diagram of the mains showing the positions of the arc lamps is given in Fig. 2.

There are 34 arc lamps in all, three of which are special Board of Trade signal lanterns for harbour purposes. The lamps are of Messrs. Crompton and Co.'s well-known "P" type, with special weather-proof hoods. They are mounted on cast-iron pillars with curved bracket arms, which present an exceedingly tasteful appearance (see Fig. 3).

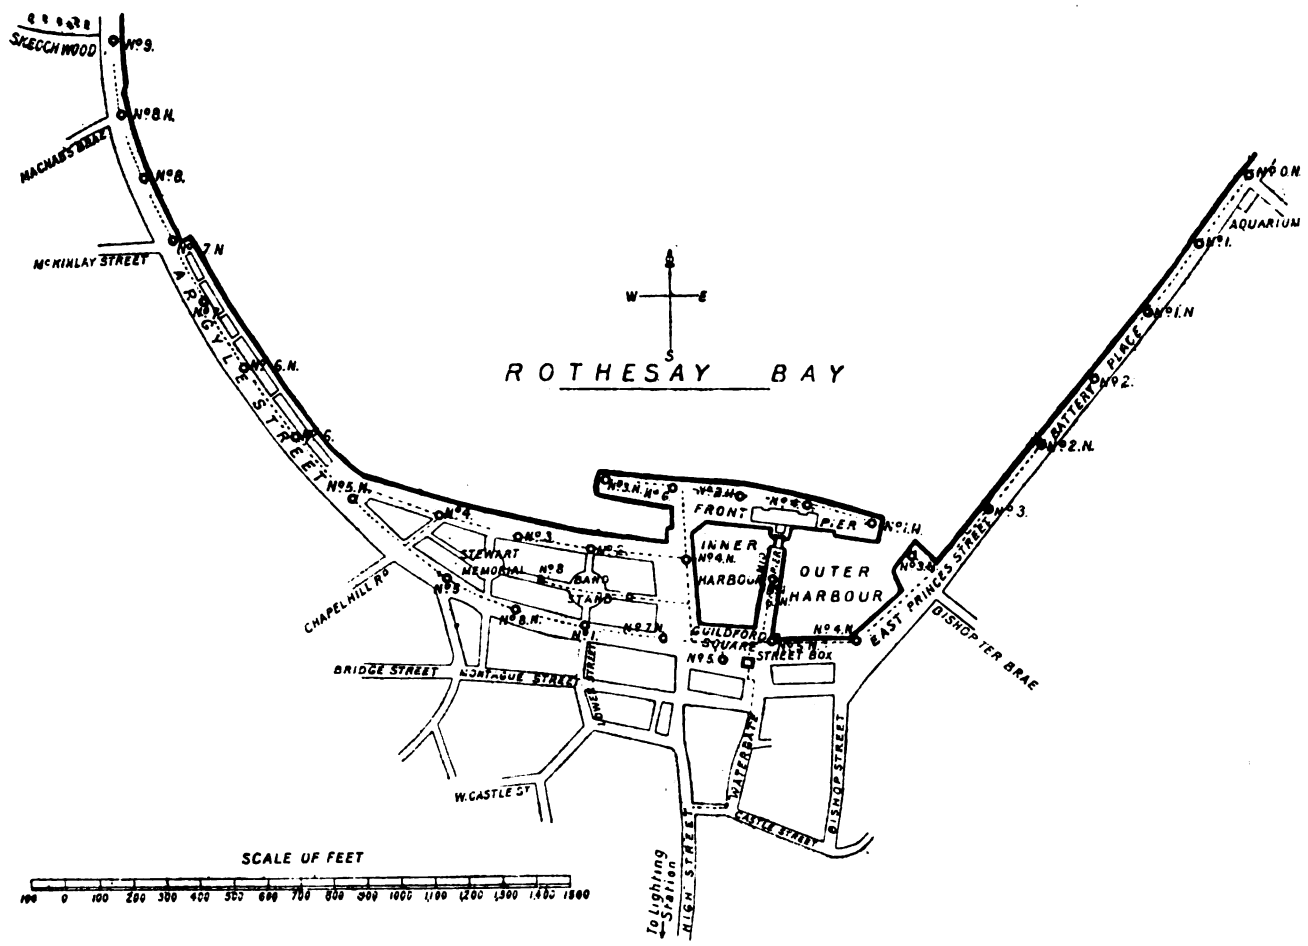

FIG 2.—Diagram of Mains, Rothesay.

Digitized by Google

The Rothesay coat-of-arms is embodied in the ornamental scrollwork of the bracket, and also embossed on the base of the pillar. They were designed and made by Messrs. Walter Macfarlane and Co., Saracen Foundry, Glasgow, who also made the special signal lanterns for the harbour. The arc lamps are arranged in four circuits, two of nine lamps each and two of eight lamps each. They are also arranged in alternate circuits, so that one half of the lamps can be switched off at midnight if desired. The switches for this purpose are arranged in the base of the first pillar of each of the four groups, which are all situated near the centre of the town and within a small area. Thus the attendant has no great distance to cover when switching off. Each lamp has an automatic cut-out, substitutional resistance, and special cutting-out switch for switching off the lamp, and at the same time substituting the resistance, leaving the lamp perfectly "dead" for examination and retrimming, should such be necessary.

The installation was successfully started up in September of last year, and has been running satisfactorily ever since, the new light being much appreciated alike by the natives of the town and the "stranger within its gates." Now that Rothesay has led the way in introducing the electric light, it is expected that most of the other coast towns on the Clyde will follow its example, as there is no mistake that the popularity of Rothesay will be greatly increased owing to the much enhanced appearance which the electric lighting has given to the town, especially the esplanade and pier, which are, of course, the parts most frequented by visitors. Messrs. Lowdon Bros. and Co. are to be complimented on the shortness of the time which elapsed between the commencement of the work and the switching on of the installation. The cable laying was commenced about the middle of May, 1899, and the lighting was started up on Sept. 12 following. In view of the amount of work which had to be got through and the delays, inseparable from the fact of all material having to be shipped, this was a remarkably good performance. On behalf of the Council, Mr. J. C. Sinclair, the burgh chamberlain, did everything in his power to expedite the work, and has, since the inception of the scheme, had its success thoroughly at heart. Messrs. Lowdon Bros. and Co. have been running the plant on contract throughout the season, and so far no serious hitch has occurred. The whole work was under the supervision of Mr. George Balfour, of the firm of Messrs. Lowdon Bros. and Co., while Mr. James Allan represented the firm on the spot from start to finish of the work.

It may be mentioned, in conclusion, that the photograph of the engine-room which we reproduce herewith was taken by Messrs. Adamson and Sons, of Rothesay, together with a unique photograph showing the bay under the electric light. The latter was obtained only after repeated attempts on a very dark night. The effect obtained is very interesting, but, unfortunately, will not bear reproduction.

THE OPENING OF EDMUNDSON'S ELECTRIC SUPPLY COMPANY'S WORKS AT GUERNSEY.

On Wednesday, July 25, the official opening of the works of this company took place, being performed by Sir Thomas Godfrey Carey, Bailiff of Guernsey, in the presence of a goodly assemblage. The ceremony took place at 12.30 p.m., when those present were invited to inspect the works.

In a lengthy speech Mr. J. C. Wigham, of Messrs. Edmundson's, explained that the company was started in Guernsey in the spring of 1897 by Messrs. Edmundson's Electricity Corporation, Limited, of Westminster, who had applied to the States of Guernsey for a concession for the establishment of an electricity supply in Guernsey. The supply was now complete, Messrs. Edmundsons having found the whole of the capital required. The concession was granted by the States in the spring of 1898, and obtained the Royal assent later on in the same year. Mr. James Duquemin, sen., M.I.C.E., architect, was subsequently asked to prepare plans for the necessary buildings, while Mr. W. H. Druce, A.M.I.C.E., engineer and manager for Messrs. Edmundsons in the island, was entrusted with the designs for the electrical equipment of the station. The building operations were commenced early in 1899 and completed about a twelvemonth after, the contract for the building work being let to Mr. J. H. Mansell, of St. Sampson's, Guernsey.

Sir Thomas Godfrey Carey said that the company had been one of high standing from the commencement. It had proved great efficiency, and deserved the full confidence of the community. He expressed the hope that every success would crown its labours, and returned thanks to Mr. Wigham for the able way in which he had explained the working of the station. The concern would be crowned with success, both for the shareholders and for the benefit of the island of Guernsey. Sir T. G. Carey then declared the works open.

Mr. Wigham prayed Sir Thomas to set the machinery in motion, the switch being turned on by Miss Carey (daughter of Sir Thomas). Mr. Edmundson subsequently presented the switch button to Sir Thomas, and three cheers for the success of the company were given by those assembled, who were then invited by Mr. Wigham to luncheon at the Yacht Hotel, where host Pells had provided a menu worthy of the occasion, and at 1.30 p.m. about 60 sat down to partake of it. After full justice had been done to the fare provided, and the usual loyal toasts had been duly honoured,

Magistrate Brouard was called upon to propose "Success to the Electric Light in Guernsey.' He said he remembered the good old time when they had to depend on oil lamps for their light. Great progress was made when gas was introduced, but now, in its turn, electric light in the island was an accomplished fact. He was sure that everyone would join in the toast which he had the honour to propose.

Mr. Edmundson, in responding, said he was glad to see so many present. He thought that the electric light in Guernsey would be a success. The work of installation had been done in a thorough and up-to-date manner.

Mr. Wigham, in proposing "Continued Success to the Island of Guernsey," said the directors of Edmundson's Electricity Corporation, Limited, advocated installations in small towns. In Guernsey they already had penny-in-the-slot meters, and he hoped that artisans would procure them. Personally, he hoped to see the electric light the poor man's light in Guernsey. The company thought it would be able to pay a small dividend at the end of the first complete year of working. Up to now three hotels had availed themselves of the new light. As to public lighting for town and harbour, they intended to have a friendly contest with their friends the gas company. They also wished to see motors installed for working cranes, printing machinery, lifts in hotels, and the stone-breaking machines at St. Sampson's, etc. Many houses and business places in the island would also some day go in for electric lighting. All the gas companies had given notice that the price of gas would be increased owing to the rise in price of coal, but it was not his company's intention to raise the price of their light. On the contrary, they would only be too pleased, as customers increased, to make a reduction.

Mr. Henry Giffard, responding to the toast, said that Mr. Druce had had the coolness to provide coolness to his guests in the shape of electric fans, and he thanked him for them. He was a born Guernsey man, but had spent the greater part of his life away from his native home, and it was the spot to which he had always wished to return. He attributed the success attained by Guernsey to its always being willing to accept light, and to-day they had accepted a new light. He remembered the time when their only light came from tallow candles, and no Bryant and May's matches to light them with. But progress had made a big step, and he could only wish continued success to the island of Guernsey.

Sir T. G. Carey proposed "Our Visitors," and gave them all a hearty welcome. It gave him great pleasure to see present so many gentlemen from England and Jersey, and he hoped that the island would profit by the light thrown into it by visitors.

This toast was responded to by Mr. W. H. Dickson, manager of the Jersey Railway Company, and Alderman Chave, of Weymouth, the latter gentleman remarking that

Digitized by Google

the Weymouth Town Council had been talking about the electric light for four years, and he hoped that they would soon have it.

"The Contractors" was proposed by Mr. GERVASE PEEK, of Guernsey, and responded to by Mr. T. CALLENDER, of Callender's Cable Company.

The toast, "The Chairman," proposed by Mr. T. W. PRESSLAND, was heartily received, and Sir THOMAS, in reply, said he was pleased to be present. He appreciated the electric company, and what he had seen of their work was a proof that the company was a sound and reliable one. The intercourse between the States and the company had always been cordial. There was one gentleman whom he thought had been forgotten in the toast list, that was Mr. D. uce, who had been the channel of communication between the States and the company, and he offered his personal thanks for the way in which that gentleman had managed the affairs of the company.

Mr. DRUCE, in a few chosen words, thanked the Bailiff for his kind remarks, and the company for the way in which they had drunk his health.

The proceedings terminated at 4 p.m.

The following is a short description of the works: As mentioned above, the work of erecting the generating station buildings, which are situated at Les Amballes, was commenced early in 1899 and completed in about 12 months. No less than 4,000 tons of earth and rock had to be removed from the site before the foundations could be put in, owing to the slope of the ground, which, therefore, necessitated putting the floors at different levels. On approaching the works, the first thing noticed is the chimney stack, which is 100ft. high and 5ft. diameter inside, the top being finished off with a neat cap of Guernsey granite. The buildings are built of local granite throughout, with the exception of the temporary end to the boiler and engine houses. The buildings comprise a boiler-house, 36ft. by 51ft., with a bunker capable of holding about 100 tons of coal next the street; an engine-house, 24ft. by 51ft.; an accumulator-room, 17ft. by 51ft.; a private office, large public office, workshop and lavatories, etc. The premises are well lighted, and sufficiently commodious for the purposes for which they are designed. An important point is that they are arranged so as to facilitate extensions when required, without disturbance to the existing structure or plant.

There are at present installed two Babcock and Wilcox 100-h.p. water-tube boilers, each capable of evaporating 3,500lb. of water per hour at a pressure of 160lb. per square inch, and room has been left for a new boiler, double the size of the existing ones, which is to be delivered in October, and which is to be fitted with mechanical stokers. In the boiler-house are also two feed pumps, one driven by steam, and the other by an electric motor; one of these is intended to act as a reserve, and the piping and valves are so arranged that in case of the failure of one pump the other can be used to supply either boiler. At the back of the boilers is the main flue leading to the chimney, and outside the boiler-house is a Green's economiser. Like the feed pipes, the steam-pipes to the engines are also in duplicate, rendering very remote any chance of a complete failure of steam to the engines. The engine-room contains two Belliss engines of 80 i.h.p. each, coupled direct to two-pole 74-kw. dynamos, running at a speed of 500 revolutions per minute, by Messrs. Thomas Parkers, Limited. These generators supply 160 amperes each at 460 volts terminal pressure. Room is left for two more engines, each capable of supplying 5,000 8-c.p. lamps, one of which is to be erected this autumn. Facing the engines is the switchboard. This has a base of Sicilian marble framed with a carved mahogany moulding. All the measuring instruments, etc., are of the Kelvin type. The battery of accumulators consists of 230 23-plate D.P. cells in glass boxes, and has a normal output of 336 kilowatt-hours and a maximum discharge rate of 80 amperes, being therefore capable of supplying 1,200 lamps for nine hours when fully charged.

The main feeder and distributor cables, of which there are at present about seven miles laid, were supplied by Messrs. Callender's Cable and Construction Company, Limited. They are of sufficient capacity to supply 10,000 lamps, so that the streets will not require to be opened again until the system has grown very considerably.

The feeders are of the triple-concentric lead-covered, armoured type, laid direct in the soil. Distributors of the three-core type are used, and these are laid in the same manner. A low-pressure three-wire system of distribution has been adopted, with a pressure of 210 volts at the consumer's lamps. The price charged per unit for lighting is 7d. and 4d., while 4d. and 1½d. is charged per unit for power, on the maximum demand system. Supply was commenced in February, 1900, and the undertaking gives every promise of complete success, well over the equivalent of 5,000 8-c.p. lamps having already been connected up to the mains. Included in this load is a fair number of motors. No street-lighting has at present been done. St. Peter Port is the principal centre supplied, the population of which amounts to 18,000. The local gasworks are owned by a company, the price charged per 1,000 cubic feet of gas being 4s. In conclusion, it may be added that Mr. W. H. Druce, A.M.I.C.E., is acting as Messrs. Edmundson's resident engineer and manager in Guernsey.

THE LEGAL RELATIONSHIP OF THE SUPPLY COMPANY TO THE CONSUMER.

[FROM A LEGAL CORRESPONDENT.]

In view of the provisions of the Electric Lighting Acts which render compulsory the supply of electricity to the private consumer, it is sometimes important for the company to have an exact idea of their legal rights and responsibilities. Foremost among a long list of penalties to which the company may become liable are the penalties for default in supplying energy, which are imposed by Clause 30 of the schedule to the Electric Lighting (Clauses) Act, 1899. It is not to be supposed, however, that a company is unable to protect itself, or that it is bound to supply electricity to all comers. Although it is provided by Section 19 of the Electric Lighting Act, 1882, that every company or person within the area shall be entitled to a supply, and by Section 20 that no undue preference shall be shown to any local authority, company, or person, yet this does not mean that the company need lay wires at their own expense for the accommodation of everyone. The whole matter is now regulated by certain sections in the schedule to the Electric Lighting (Clauses) Act of 1899. After the provisions of Section 21, which provide for the compulsory laying of street mains, it is provided in Section 27 that the undertakers shall furnish a supply to everyone whose premises are situate within 50 yards of such mains, and that they must furnish and lay any electric lines that may be necessary for the purpose, provided that the cost of (1) wires laid on the property of the owner, (2) of so much of any line as it may be necessary to lay for a greater distance than 60ft. from the main, shall, if the undertakers so require, be defrayed by the owner or occupier. The undertakers may also require security for the payment of rent by the occupier.

As electricity is still a comparatively new commodity, we are unable to refer to any cases which might be likely to render the statutes passed in relation thereto more easy of comprehension. The close analogy which exists between electricity, on the one hand, and gas and water, on the other, may, however, prove to be of assistance in our researches.

"Consumer" is defined by Section 1 of the schedule to the Electric Lighting (Clauses) Act, 1899, to mean "any body or person supplied or entitled to be supplied with energy by the undertakers." The "undertakers" are defined by Section 2 of the same Act to be "the authority, company, or other person named for that purpose in the special order." In connection with this article we may take it that the supply company are "owners" or "undertakers." In dealing with the Electric Lighting (Clauses) Act of 1899, it is important to observe that it has no application to the administrative county of London (see Section 2). Nevertheless, the form of provisional order hitherto in common use is to all intents and purposes identical with the schedule to the Act of 1899,

Digitized by Google

which must now be incorporated with and form part of every provisional order made by the Board of Trade after Oct. 1, 1899.

The Electric Lighting Act, 1882, incorporates by Section 12 the provisions of the Gasworks Clauses Act, 1847, as to breaking up streets for the purpose of laying pipes, and also with respect to waste or misuse of the electricity or injury to the pipes. It also incorporates Sections 38 to 42 and Sections 45 and 46 of the Gasworks Clauses Act, 1871, as to the recovery of electricity and meter rents. In order to ascertain the rights of a supply company to recover their reasonable charges from private owners it is therefore necessary for us to refer to the incorporated sections of the Gasworks Act, and the cases which have from time to time arisen thereunder.

The incorporated sections of the Gasworks Clauses Acts, 1847 and 1871, are to be construed for the purposes of the Electric Lighting Act, 1882, as if "gas" meant "electricity," and as if "pipe" meant "electric line," and "works" meant works as defined by the Electric Lighting Act, 1882, and as if "the limits of the special Act" meant the area within which the undertakers are authorised to supply electricity under any license, order, or special Act (see Electric Lighting Act, 1882, Section 12, Sub-Section 3). "Works" are defined in Section 32 of the Act of 1882 to be, and to include, electric lines, also any buildings, machinery, engines, works, matters, or things of whatever description required to supply electricity and to carry into effect the object of the undertakers under the Act. Bearing the above section in mind, we shall be entitled to treat the cases which have arisen with reference to gas as authoritative in relation to the supply of electricity. For the sake of clearness it will be convenient to substitute the word "electricity" for "gas," and the words "electric line" for "pipe," in setting out the incorporated sections.

By Section 39 of the Gasworks (Clauses) Act, 1871, it is provided that in case any consumer of *electricity* supplied by the undertakers leaves the premises where such *electricity* has been supplied to him without paying the rent or meter rent due from him, the undertakers shall not be entitled to require from the next tenant of such premises the payment of the arrears left unpaid by the former tenant, unless such incoming tenant has undertaken with the former tenant to pay or exonerate him from the payment of such arrears. In connection with this section it is important to remember that by Section 27 of the schedule to the Electric Lighting (Clauses) Act the undertakers are entitled to demand security for the payment of rent, therefore, if suitable precautions are taken, no liability need be incurred.

By Section 40 of the Act of 1871, if any person supplied with electricity, or with any electric meters, or fittings by the undertakers neglects to pay to the undertakers the rent due for such electricity, or the rent or money due to the undertakers for the hire or fixing of such meter, or any expenses lawfully incurred by the undertakers in cutting off the electricity from the premises of such person, the undertakers may recover the sum so due in like manner as a penalty under the Act. The use of the word penalty does not make the proceedings criminal (see R. *v.* Master or Martin, L.R., 4 Q.B., 285; 38 L.J., 73; 19 L.T., 733; 17 W.R., 442; 10 B. and S. 42), and the money due is in reality only in the nature of a civil debt, recoverable by complaint and order under Sections 6 and 35 of the Summary Jurisdiction Act, 1879. Thus, in the case of R. *v.* the Justices of Torquay (1895: 1 Q.B., 1; 64 L.J., 70; 71 L.T., 574; 43 W.R., 59), it was decided that where the justices, upon an information in writing, made an order that the defendant should pay a cab fare and costs due under Section 66 of the Town's Police Clauses Act, 1847, and that in case of non-payment he should be imprisoned in default of a sufficient distress, it was held that the order was bad, and that the fare was recoverable only in the manner in which "civil debts" are recoverable in a court of summary jurisdiction under Section 35 of that Act. There is no necessity, however, to have recourse to these decisions in the case of a recovery of electricity rents, for it is provided by Section 12, Sub-Section 3, of the Electric Lighting Act, 1882, that all offences, forfeitures, penalties, and damages under the incorporated provisions of the said Acts—*e.g.*, the Gasworks Clauses Acts—or any of them, may be prosecuted, and may be recovered in manner by the said Acts respectively enacted in relation thereto, provided that sums recoverable under the provisions of Section 40 of the Gasworks Clauses Act, 1871, shall not be recovered as penalties, but may be recovered as civil debts. The recovery of civil debts in a court of summary jurisdiction is provided by Sub-Sections 6 and 35 of the Summary Jurisdiction Act, 1879 (42 and 43 Vict., cap. 49).

It must not be supposed that the above sections limit the electric supply company to taking proceedings in a court of summary jurisdiction. It is provided by Section 41 that whenever any person neglects to pay any rent or sum due and payable, the undertakers may recover the same, with full costs of suit, in any court of competent jurisdiction; and the remedy of the undertakers under this enactment are, in addition to their other remedies, for the recovery of such rent or sum.

The register of a gasmeter is *primâ facie* evidence of the quantity consumed, and two justices may settle the difference (see Gaslight and Coke Company *v.* Cresswell, 1897, 61 J P., 699.) An important difference is made with regard to an electric lighting meter, the register of which affords conclusive evidence. Thus Clause 54 of the Electric Lighting (Clauses) Act of 1899, after declaring that in the cases of dispute the electric inspector must decide whether the meter is or is not in proper order, provides that the register of the meter shall be conclusive evidence of the value of the supply. It is also interesting to notice that the accuracy of a meter, which was sworn to be perfectly correct by a Government inspector, was successfully disputed at Wandsworth Police Court July, 1887 (see Wandsworth and Putney Gas Company *v.* Rye, 31, Sol. J., 633).

In the next place, it is important to consider the time within which proceedings for the recovery of an electric lighting rate should be instituted. This seems to be regulated by Section 11 of the Summary Jurisdiction Act, 1848, which provides that in all cases where no time is specially limited, such complaint shall be made or information laid within six calendar months from the time when the matter of it arose. That section has been applied to the hearing of a summons before justices for arrears of water rate under Section 85 of the Waterworks Clauses Act [see East London Waterworks Company *v.* Charles (1894), 2 Q B., 730; 53 L J., 209; 42 W.R., 702; 58 J.P., 764], and in the absence of express authority it is submitted that an undertaker would be unable to recover any rates beyond those which accrued due within six months of the date of the demand.

By Section 23 of the Electric Lighting Act, 1882, it is provided that any person who maliciously or fraudulently abstracts, causes to be wasted or diverted, consumes or uses any electricity, shall be guilty of simple larceny, and punishable accordingly. The introduction of this clause rendered it unnecessary for the Court to say whether electricity was a "substance" capable" of being stolen, a question which arose with regard to gas, but which was answered in the affirmative by the case of R. *v.* White (21 L. T., 159). A consumer of gas is liable to the penalty prescribed by Section 18 of the Gasworks Clauses Act, 1847, for altering a pipe communicating with a pipe belonging to the company so as to increase the supply without the company's consent, although fraud is not intended or effected [Wood *v.* West Ham Gas Company (49 J.P., 662; 62 L.T., 817)]. Having regard to the express words of Section 23, which apparently make "fraud" and "malice" an essential ingredient of the offence, the foregoing case would not appear to apply in the case of electricity.

Sections 18 to 20 of the Gasworks Act of 1847 impose penalties upon persons for (*a*) fraudulently using *electricity* of the undertakers, (*b*) wilfully removing or damaging *electric* wires, and (*c*) renders all persons breaking *electric wires*, pillars, or lamps liable to pay for the damage done to an extent not exceeding £5. Section 38 of the Act of 1871 imposes penalties for injuries to meters. Special provisions with regard to these instruments now form an integral part of every provisional order [see Clauses 49 to 59 of the schedule to the Electric Lighting (Clauses) Act, 1899].

STANDARDS OF E.M.F.

BY JOHN HENDERSON, D SC., F.R S E., A.I.E.E.

(Concluded from page 124.)

Time or Diffusion Lag.—No matter how accurately we may know the temperature of a cell and have determined its temperature coefficient, it does not always follow that we are justified in applying it in order to calculate the E M.F. of the cell under all circumstances, as it is found that the change in the E M.F. does not immediately follow on the change of temperature, but, in general, lags behind it. This is known as "time lag," and is due to the slowness of the process of diffusion in the cell when the density of a particular layer of solution has been altered by the temperature change. Many experiments have been made to determine the amount of the time lag in cells and the limiting rate of fluctuation of temperature that may be permitted whilst using the ordinary coefficient. The most important results in connection with this point are those of Ayrton and Cooper, who have shown that in a cell of the Board of Trade pattern, if kept at a constant temperature for 30 minutes before use, the E.M.F. will not differ more than 1 part in 10,000 from its calculated value. In a still more recent investigation it has been shown that in cells made up in accordance with Dr. Kahle's specification, the time lag amounted to the following values with various rates of temperature change:

·0004 volt,	temperature	changing	1deg. C.	in	7	minutes,
·00025 „	„	„	„	„	15	„
·00005 „	„	„	„	„	30	„

whilst in the case of the Board of Trade cell the time lag amounted to more than four times the above values. The time lag must depend largely on the construction of the cell and on its treatment, as, if shaken, the rate of diffusion would be much greater than if kept perfectly still Callendar states that the E.M.F. of a cell kept perfectly still may go on changing for weeks before it reaches a steady value, consequent upon a sudden change of temperature. The Callendar crystal cell has an advantage over the other forms in this respect, since having no liquid for diffusion currents to be set up in, the lag is very small.

The Clark Cell Supplying a Current.—Although it is not usual to take any appreciable current from a standard cell in ordinary testing, yet in view of possible accidental short-circuits it is advisable to investigate how far the generation of such currents will affect the E.M.F. of the cell. On this subject a number of interesting experiments have been made. According to Skinner, the amount of polarisation in a Clark cell is directly proportional to the current density, but if the resistance of the external circuit is not less than 100,000 ohms, polarisation need not be taken into account. In the Carhart-Clark cell, when the resistance of the external circuit was 300,000 ohms, no polarisation was detected, and when it was 1,000 ohms the polarisation only amounted to 1 part in 10,000 in five minutes. In connection with the production of larger currents, such as those produced by an accidental short-circuit, Fisher gives some interesting and remarkable data. In one experiment, after allowing a Clark cell to supply a current on a potentiometer wire due to a want of balance of ·01 volt for one minute, the E.M.F. fell 6 parts in 14,000, and the cell required 10 minutes' rest to recover, whilst after an actual short-circuit for 30 seconds through 2in. of No. 18 copper wire, the E M.F. fell 1 part in 1,400, and required 30 minutes' rest to recover. The rate of recovery could in every case be accelerated by slightly charging the cells from a higher E.M.F.; thus a cell which had been short-circuited for 20 hours through a few inches of thick copper wire, and whose E.M.F. had fallen to 0·17 volt, recovered after 24 hours' rest, but the same cell recovered in 2½ hours when charged from an E.M.F. of 1 4 volts. Also a cell short-circuited for five seconds whose E M.F. had fallen 8 parts in 14,000 recovered in 10 seconds when charged from an E.M.F. $\frac{1}{10}$ volt in excess of its normal value. Fisher also found that the internal resistance of Clark cells rose greatly after standing for a long time unused, but that a temporary short-circuit would reduce this in some cases from several thousand to a few hundred ohms, so that an occasional short-circuit far from being injurious to the cells was, if anything, rather beneficial.

To sum up the information we have on the Clark cell, it will be seen that it by no means comes up to the level of an ideal standard of E M.F., the chief defects being inconstancy of E.M.F. over long intervals of time and the want of certainty as to whether under given conditions we are justified in applying corrections, such as those for temperature change, which must in many cases have been obtained under totally different conditions of which we have no knowledge; and even if we did know the conditions, Jaeger's experiments on the change of constitution of the zinc sulphate indicate that the entire life history of each cell must be known before we can put much reliance on it. With regard to the most suitable form of Clark cell for commercial purposes, the Rayleigh H-cell is much too fragile to stand the knocking about such a cell must receive. The Board of Trade cell, whilst being more compact and portable, does not fulfil the other conditions necessary. The Carhart-Clark cell is open to the same objections. The Callendar crystal cell appears to be the most satisfactory form yet devised, the time lag being small and its construction admitting of its being completely immersed in a water-bath, although in other respects it is open to the same objections as the others.

Before leaving the subject of the Clark cell it will be well to look briefly at the methods of preparing the materials required in its construction and the probable impurities they contain. The mercury as supplied by chemists can, in general, be relied upon for purity if it has been redistilled, as can also the zinc rods. The greatest difficulty will doubtless be experienced in obtaining pure neutral mercurous sulphate; this as supplied usually contains mercuric sulphate, which under the action of water splits up into an acid and a basic salt; the latter is insoluble in water and can readily be detected by its yellow colour; it does not affect the E M.F. The acid salt, however, must be got rid of, and, as it is soluble in water, it is generally recommended to wash the mercurous sulphate well with distilled water, and grind it up into a paste with some pure mercury. In one specimen of mercurous sulphate which had a strong acid reaction, this process was adopted by the author with very poor results, whilst in another case mercurous sulphate, which at first gave no acid reaction, six months later turned yellow, thus indicating that decomposition had occurred. A cell employing some other salt more stable and more easily obtained pure would be much more likely to give satisfactory results.

Cadmium Cells.—Many experiments have been made with various combinations of metals and salts, with a view to obtain a primary cell free from the defects found to exist in the present Clark cell, and one of the most important results of these experiments has been the production of the cadmium cell. This cell appears to have been first devised by Weston, in America, in 1891 as the result of endeavours to obtain a cell with a small or negligible temperature coefficient. Weston, recognising that the most important factor determining the variation of the E.M.F. of the Clark cell with temperature was the alteration in density of the $ZnSO_4$ solution, chose as the electrolyte in his cell a salt which was equally soluble in hot and cold water—viz, cadmium sulphate. The electrodes of the cell are mercury and an amalgam of cadmium and mercury. The mercury is covered with a layer of paste consisting of neutral mercurous sulphate, mercury, and cadmium sulphate, the remainder of the cell being filled with a saturated solution of neutral cadmium sulphate. The form of cell adopted by Weston is shown in the accompanying figure (Fig. 5). According to Weston, the E.M.F. is 1·019 volts, and the temperature coefficient ·01 per cent. per 1deg. C. In 1893 Dearlove published the results of some experiments on cadmium cells of the Rayleigh H-form. No mention is made by him of any test for acidity of the paste or $CdSO_4$ solution, or whether any special difficulty was experienced in obtaining neutral salts. The only precaution specially mentioned was that the Hg_2SO_4 should be present in excess, otherwise the E.M.F. obtained was too high. After construction, the E.M.F. of his cells fell by 4 parts in 10,000 in 16 days. Experiments were also made using various proportions of mercury

Digitized by Google

and cadmium in the amalgam, a pure cadmium electrode giving an E.M.F. of 1·0800 volts, whilst a proportion of 1 Cd to 100 Hg gave an E.M.F. of one volt. The other values obtained have been plotted on the accompanying curve (Fig. 6), and show a rapid rise in E.M.F. with the proportion of cadmium till a proportion of 7 Cd to 100 Hg is reached, after which the curve becomes much flatter; for all proportions below 14 in 100 the E.M.F. was found to be very unsteady. Experiments on the temperature coefficient also appear to have been made on a cell having

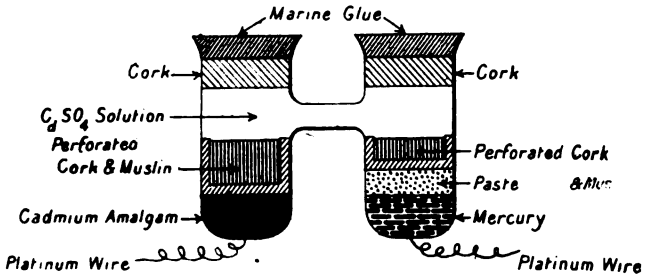

FIG. 5.

an amalgam of 1 Cd to 5 Hg, and a value of ·016 per cent. per 1deg. C. between 15deg. to 43deg. C. was obtained; the alteration of E.M.F. appeared to be entirely due to the action of heat on the amalgam, the E.M.F. falling as the temperature rose. Dearlove also states that a considerable time lag was observed in the change of the E.M.F. with temperature, but gives no data. In 1894 Jaeger and Wachsmuth published the results of a research on the cadmium cell, in which they give 1·025 volts (true) as the E.M.F. of the cell, and the following expression for the temperature variation:

$$E_t = E_0 - 1{\cdot}25 \times 10^{-5}\, t^\circ - {\cdot}065 \times 10^{-5}\, t^{\circ 2}.$$

They mention that considerable quantities of impurities in the salts only alter the E.M.F. by a few parts in 10,000. The same authors in a later paper give the results of a comparison of seven cadmium cells in series with five Clark cells in series, the cadmium cells being of the H-type.

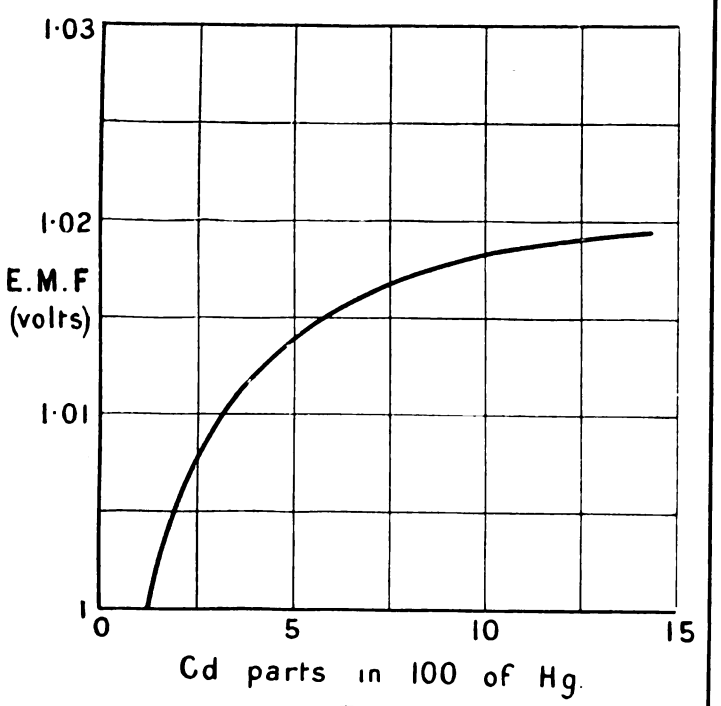

FIG. 6.

Assuming the E.M.F. of the Clark cell to be 1·435 volts at 15deg. C., they found the E.M.F. of the cadmium cell to be 1·019 volts at 20deg. C. The proportion of mercury to cadmium in these cells was 6 to 1, the Hg_2SO_4 was free from acid and basic salt, and the $CdSO_4$ gave no acid reaction. The temperature variation was expressed in the following relation:

$$E_t = E_{20} - 3{\cdot}8 \times 10^{-5}\,(t^\circ - 20) - {\cdot}065 \times 10^{-5}\,(t^\circ - 20^\circ)^2.$$

As far as ordinary impurities are concerned, they appear to produce a very small effect on the E.M.F. of the cell, one of the most likely to occur being zinc in the cadmium. This Jaeger showed raised the E.M.F. by only ·00019 volt when present to the extent of 1 per cent.; also an increase of 1 per cent. in the amount of cadmium in the amalgam raised the E.M.F. by ·001 volt. The cadmium sulphate solution was saturated by shaking up powdered $CdSO_4$ and distilled water, and allowing to stand for a long time. Any acidity could be neutralised by digesting with cadmium hydrate, made by precipitation from $CdSO_4$ with caustic soda. In a paper dated 1897, Jaeger gives a detailed description of the form of cadmium standard cell adopted by the Reichsanstalt; the Rayleigh H-form of cell is employed, and the amalgam has the composition 6 Hg to 1 Cd; the temperature coefficient is given as ·004 per cent. per 1deg. C. at 20deg. C., and it is stated that the E.M.F. is independent of the proportion of mercury in the amalgam between 6 and 13 parts to 1 of Cd. Another important contribution to our knowledge of the cell was made in 1897 by Cohen, who showed that there is a break in the solubility curve of $CdSO_4$ at 13deg. C., above which temperature it is constant; this, he suggests, will account for the irregularities in the behaviour of cadmium cells that had been observed at low temperatures. A similar observation has been made by Callendar and Barnes, two different rates of temperature variation having been obtained at temperatures between 0deg.-10deg. C., according to the treatment of the cell; this they suppose due to the existence of two hydrates of $CdSO_4$, similar to the two zinc sulphates which may occur in the Clark cell. In the most recent of their communications on the cadmium cell, Jaegar and Kahle admit irregularities in the behaviour of the cell at low temperatures, and recommend that the cell should only be used at temperatures between 20deg.-70deg. C. Also taking the most recent value for the Clark cell to be 1·4328 volts at 15deg. C., they give 1·0186 volts as the E.M.F. of the cadmium cell at 20deg. C.

From a careful study of the results of the experiments made by different physicists it will be seen that there are several points in connection with the cadmium cell that still remain to be cleared up, and several statements that are apparently at variance with one another that call for further investigation. As regards the question of acidity of the $CdSO_4$ and Hg_2SO_4, Jaeger and Wachsmuth specify neutral salts, although afterwards they state that acidity produces no effect. The next point of importance is the effect on the E.M.F. of varying the composition of the amalgam. Jaeger states that an addition of 1 per cent. Cd to the amalgam increases the E.M.F. by ·001 volt, whilst Dearlove's results show that up to 7 Cd in 100 Hg this variation of E.M.F. obtains, but from 7 to 14 Cd in 100 Hg the number is considerably less, being about ·0004 volt per 1 per cent. Cd added. Nor is Jaeger's later statement, that the E.M.F. is independent of the proportion of Cd and Hg within the limits of 7·7 and 16 parts of Cd to 100 of Hg, consistent with Dearlove's results, which show a variation of E.M.F. within these limits. The influence of impurities on the E.M.F. of the cell has been shown by all experimenters to be very small, comparatively large quantities of zinc, iron, and magnesium added to the $CdSO_4$ solution producing variations of only a few parts in 10,000 in the E.M.F. When we come to the temperature coefficient of the cells, however, we are met with a considerable divergence of opinion as to its actual value, although all experiments agree in showing it to be very small. The uncertainty in making the measurement may perhaps be largely due to the fact that the total change in E.M.F. of the cell through a range of 20deg.-30deg. C. falls within the limits of possible inaccuracy in calculating the E.M.F. of the Clark cell, which seems always to have been employed as the standard. Weston gives ·01 per cent. per 1deg. F. over a range of 200deg. F. as the maximum observed change in the E.M.F. This corresponds to a variation of ·018 per cent. per 1deg. C. A number of results by Dearlove are interesting as showing how the temperature coefficient depends on the composition of the amalgam. For cells having amalgam 1 Cd to 5 Hg the following numbers were obtained:

Range.	Coefficient.
0deg.-15deg.	·022 per cent.
15deg.-27deg.	·05 ,,
27deg.-43deg.	·035 ,,

Digitized by Google

The most interesting values, however, were those obtained from a set of five cells in which the amalgam had the composition 1 Cd to 7 Hg, and which are given in the following table:

Cell.	E.M.F.	Coefficient 15·5°-33·5°.	Coefficient 15·5°-64°.	Coefficient 33·5°-64°.
1	1·0197	·007 %	·008 %	·008 %
2	1·0196	·006 %	·010 %	·013 %
3	1·0194	·003 %	·010 %	·015 %
4	1·0189	·003 %	·010 %	·014 %
5	1·0193	·004 %	·007 %	·008 %

Taken all over it would appear that the temperature coefficient diminishes as the proportion of mercury in the amalgam increases, and the last column would indicate an increase in the temperature coefficient with rise of temperature. The change from abnormally low values at low temperatures to abnormally high values at high temperatures in some cases, points to some change in the constitution of the salt. Jaeger's two formulæ correspond to coefficients of ·001 per cent. and ·0038 per cent. Another possible explanation of the wide differences observed in the temperature coefficients of the cells is to be found in the different values of the time lag in different cells.

The Cadmium Crystal Cell.—This represents the latest form of cadmium cell, and was introduced independently by Prof. Callendar and by the author, the object being to get a cell without free liquid, and which would be portable. The following Fig. 7 shows the cell as constructed by the

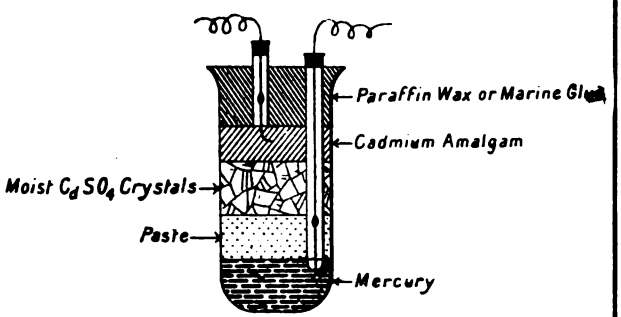

Fig. 7.

author; Fig. 8 shows an enlarged view of one of the contact wires. Several sets of these cells were made up in order to test certain disputed points in connection with cadmium cells. A set of four cells were made up with Hg_2SO_4 and $CdSO_4$ sold as pure, but which, when tested, were found to be very strongly acid. The Hg_2SO_4 was first made up into a paste with mercury, water, and a few crystals of $CdSO_4$ until it was quite stiff, when it was placed on the

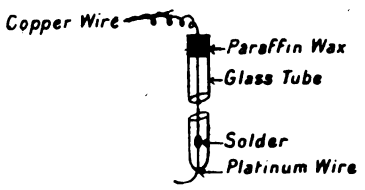

Fig. 8.

top of the pure mercury in the test tube. A thick layer of $CdSO_4$ crystals ground small in a mortar was placed above the paste, and then moistened with a few drops of distilled water. The amalgam was melted in an evaporating basin, and consisted in all cases of 1 Cd to 6 Hg by weight (M.P. 60deg. C.); this was poured on the top of the $CdSO_4$, and the connecting wire placed in it before it solidified. Paraffin-wax or marine glue was poured above the amalgam to seal up the cell. A set of two cells similar to the above, but to which strong H_2SO_4 had been added to acidify the paste and $CdSO_4$ crystals, were made up to test whether added acid would have any different effect to the ordinary acidity of the salt. A set of four cells were made up with perfectly pure and neutral $CdSO_4$ and Hg_2SO_4 (obtained from Messrs. Kahlbaume, of Berlin), and a cell acidified with H_2SO_4 was also made up with pure chemicals. The E.M.F.'s of the cells were compared on a specially-constructed potentiometer, the standard of reference for temperature variation experiments being a cadmium cell kept always at one temperature. The E.M.F. of this cell was measured absolutely by balancing it against the difference of potential between the terminals of a standard resistance carrying a current which was measured on a current balance. The results of over 200 observations at various temperatures are given below:

I.—Cells Containing Impure Salts.

Cell.	10deg.-15deg.	15deg.-20deg.	20deg.-30deg.
1	1·0185	1·0186	1·0182
2	1·0184	1·0187	1·0182
3	1·0187	1·0187	1·0181
4	1·0187	1·0187	1·0178
Mean values	1·0186	1·0187	1·0180
Maximum variation from mean—	·0002	·0001	·0002

II.—Cells Containing Pure Salts.

Cell.	10deg.-15deg.	15deg.-20deg.
1	1·0188	1·0187
2	1·0189	1·0188
3	1·0188	1·0186
4	1·0189	1·0188
Mean values	1·0188	1·0187
Maximum variation from mean—	·0001	·0001

Both the impure cells containing added acid had E.M.F.'s much greater than the above, and did not agree so well with one another. The values are given below:

Cells Containing Added Acid.

Cell.	10deg.-15deg.	15deg.-20deg.	20deg.-30deg.
1	1·0192	1·0191	1·0183
2	1·0196	1·0199	1·0191

The pure-salt cell which was acidified also gave a similar value. From the above results a remarkable agreement will be seen to exist between the E.M.F.'s of cells made of ordinary "commercially pure" materials and those of "chemically pure" salts, there being a difference of only 2 parts in 10,000 between the limits of 10deg. to 15deg., and exact agreement from 15deg. to 20deg. C. The temperature coefficients have also been calculated from the above values, and are given in the following tables:

I.—Cells Made from Impure Salts.

Cell.	Temperature coefficient.
1	·003 per cent. per 1deg. C.
2	·002 ,, ,,
3	·006 ,, ,,
4	·009 ,, ,,

II.—Cells Made from Pure Salts.

Cell.	Temperature coefficient.
1	·002 per cent. per 1deg. C.
2	·002 ,, ,,
3	·004 ,, ,,
4	·002 ,, ,,

The effect of added acid on the temperature coefficient is very evident, the values for the specially acidified cells being ·007 and ·006 per cent. respectively, as compared with average values of ·005 and ·003 per cent. respectively for the cells made up with impure and pure salts but not containing added acid.

Time Lag.—In order to examine the nature of the time lag which was found to exist in all cells, one of the cells in each set was kept at a constant temperature for several days and its E.M.F. measured; it was then immersed in a water-bath at a temperature about 15deg. C. higher, and kept there until its E.M.F. became constant. In all cases the E.M.F. showed a sudden drop on first heating, the amount increasing with the acidity of the cell and being about ·2 per cent. for the perfectly pure cells; the E.M.F. then rose slowly for about two hours, when it attained a steady value.

Recovery from Polarisation.—Very satisfactory results were obtained from all the cells with respect to the recovery of the E.M.F. after polarisation. One cell was connected up to a coil of 1,000 ohms resistance for five minutes, and two minutes after the circuit was broken its E.M.F. had returned to its original value. Several of the cells were short-circuited for five minutes, and after five minutes' rest the E.M.F.'s were found to have returned to within ·4 per cent. of their original value. Whilst if the cells received a small charge from an E.M.F. ·01 volt in excess of their proper value, they recovered almost immediately. The conclusions drawn from these experiments are that, so far as regards the fulfilment of the necessary conditions for an ideal standard of E.M.F., the cadmium

Digitized by Google

cell, and more especially the cadmium crystal cell, is distinctly superior to any modification of the Clark cell. With ordinary care, and no previous experience of standard cell manufacture, anyone can make up a cadmium crystal cell, and rely safely on its E.M.F. being well within ·1 per cent. of 1·0186 volts at all ordinary temperatures, whether the materials from which it is made up have been specially purified or not; the temperature coefficient of even acid-salt cells being so small that for most measurements it is not necessary to take any account of it.

LONG-DISTANCE TRANSMISSION IN TELEPHONIA.

The following is the abstract by the *Electrical World* of New York of a paper read at the fourth annual meeting of the Pacific Coast Transmission Association by Prof. C. L. Cory. The paper, which is to do with the regulation of transmission systems, takes up the problems connected with the transmission of power over a distance of 150 miles. The treatment had particular application to the system now under construction by the Standard Electric Company of California. The data of that plant was given as follows:

Length of transmission (approximately)	150 miles
Voltage	60,000 volts
Diameter of conductors (aluminium-stranded)	·75in.
Area of conductors	471,034 cir. mils
Maximum resistance per mile at 70deg. F.	·205 ohm
Frequency—periods per second	60
Distance between centres of conductors	42in.

The following are some of the constants of the line computed from the above data:

Inductance of the 150-mile transmission, or 300 miles of wire	·48 henry
Inductive reactance per mile of wire, or half-mile transmission, using 60 p.p.s.	·634 ohm
If 30 p.p.s. were used	·317 ,,
Impedance per mile of wire, or half-mile transmission, using 60 p.p.s.	·664 ,,
If 30 p.p.s. were used	·3775 ,,
Impedance factor of line (impedance divided by resistance), using 60 p.p.s.	3·25
If 30 p.p.s. were used	1·84
Resistance of 300 miles of line (two wires of 150-mile transmission)	61·5 ohms
Inductive reactance of 300 miles of line, using 60 p.p.s. (two wires of 150-mile transmission)	190·2 ,,
Inductive reactance of 300 miles of line, if 30 p.p.s. were used	95·1 ,,
Impedance of 300 miles of line, using 60 p.p.s.	200·0 ,,
If 30 p.p.s. were used	113·2 ,,
Capacity of the 150-mile transmission or 300 miles of wire (considered as two parallel cylinders)	1·43 microfarads
Capacity per mile of transmission line	·0095 ,,
Capacity reactance between two wires, per mile of transmission, using 60 p.p.s.	279,000 ohms
Capacity reactance between two wires, per mile of transmission, using 30 p.p.s.	558,000 ,,
Capacity reactance between two wires of 150-mile transmission, using 60 p.p.s.	1,860 ,,
Capacity reactance between two wires of 150-mile transmission, using 30 p.p.s.	3,720 ,,
Capacity or charging current between two wires of 150-mile transmission, using 60 p.p.s. and 60,000 volts	32·25 amperes
Capacity or charging current between two wires of 150-mile transmission, using 30 p.p.s. and 60,000 volts	16·125 ,,
Apparent energy to charge line, using 60 p.p.s. and 60,000 volts	3,348 kw.
Real energy to charge line, using 60 cycles and 60,000 volts	32 ,,
Apparent energy to charge line, using 30 p.p.s. and 60,000 volts	1,674 ,,
Real energy to charge line, using 30 p.p.s. and 60,000 volts	16 ,,
10,000 kw., using 60,000 volts at unity power factor requires 96·3 amperes per wire.	
The kilowatt loss in 150-mile transmission	855·5 ,,
Per cent. power loss in transmission	8·55 per cent.
Volts loss, per pair of wires, in 150-mile transmission, using 60 p.p.s.	19,260 volts
Per cent. volts loss, per pair of wires, in 150 mile transmission, using 60 p.p.s.	32·1 per cent.
Volts loss, per pair of wires, in 150-mile transmission, using 30 p.p.s.	10,901 volts
Per cent. volts loss, per pair of wires, in 150-mile transmission, using 30 p.p.s.	18·2 per cent.

The effect of capacity on a 150-mile line was shown by considering a single-phase transmission of 3,000 kw. at the receiving end, the pressure, 50,000 volts, to be maintained constant at the sub-station. The approximation was used of considering the line as shunted at the generator and at the sub-station by two condensers of one-sixth the line capacity each, and in the middle by a condenser of two-thirds the line capacity. With the line open at the sub-station the generator voltage is but 47,676, the line capacity causing the rise at the sub-station to 50,000 volts. With 3,000 kw. at unity power factor at the receiving end, the current required is 60 amperes at 50,000 volts. The 32·25 amperes charging current, when combined at right angles with the 60 amperes power current, requires 69·2 amperes at the generator, the resulting generator pressure being 58,800 volts. With 3,000 kw. at a power factor of 80 per cent. at the receiving end, the current required is 75 amperes at 50,000 volts, or 60 amperes power current and 45 amperes inductive current. The 32·25 capacity or charging current, when combined with the 60 amperes power current and 45 amperes inductive current, requires but 62·1 amperes at the generator, the resulting generator pressure being 60,000 volts.

In the discussion which followed, the value of induction motors in reducing the leading current on long lines was clearly shown. Artificial regulating impedance coils may be used to accomplish the same result. On the 83-mile 33,000-volt transmission line of the Southern California Power Company from San Bernardino to Los Angeles, the heavy charging current has been largely neutralised by distributing induction motors for pumping purposes at points along the line. Measurements were reported as having been made of the charging current on the 62-mile 20,000-volt line of the Yuba Power Company, which agreed very closely with the computed charging current as shown in the paper.

VOLTAIC CELLS.

In an article in the *Electrical World* of New York, Mr. A. G. Dell states that in working with voltaic cells he had rarely found two cells which would act exactly alike, one to all appearances polarising sooner than the other, though the solution used in each cell were exactly the same. With two cells, zinc-carbon, with bichromate of potash as a depolariser, he found that one would work for some time before there was any sign of polarisation, while the other would show apparent polarisation after but a few minutes. The zinc and solution in both were exactly alike. The carbon that polarised sooner was new, while the other had been used for about a year. Then Mr. Dell says, if the bichromate is the only agent that acts on a depolariser the two should act alike, excepting that one might furnish a larger current than the other on account of a difference in the connection. The connections in the two mentioned above were made at first equally good, and the current at start was equally good, but seeming polarisation set in sooner in one than the other. Local action in the carbons could not have caused a resistance, as the carbons were in the solution when not in operation, and the zincs are raised out of the solution. When the zincs were lowered, if local action in the carbons were the cause, the fall-off should have taken place at once, and not started with a current equal to that of the better cell and then fallen off in a few minutes. The author then states that he had often found a cell which, after working well for a time, would suddenly get in a condition such that the time for apparent polarisation to commence would be shortened, and he had also found just the reverse. These remarks applied to the cells used separately, and not connected up in series or parallel. Mr. Dell then wishes to know if it can be that the self-induced impulses that dart around the circuit (the cells being used with coils, and the current being rapidly interrupted) produce some changes at the connections of some carbons and none or little at others? If this were the case, it was possible an increase in resistance at the carbon connections was the cause, the increased resistance disappearing when the cells were left idle for a short time,

ALTERNATING-CURRENT INDUCTION MOTORS.*

BY A. C. EBORALL, ASSOCIATE.

(*Concluded from page 132.*)

Performance.—The Heyland motors standardised for circuits of 40, 50, and 60 cycles are designed in three ways, as follows: (*a*) To start without load. Under these circumstances the starting current does not exceed four-fifths of the full-load running current. (*b*) To start with two-thirds of the full-load torque. Under these circumstances the starting current does not exceed 1½ times the full-load running current. (*c*) To start with full-load torque. Under these circumstances the starting current does not exceed twice the full-load running current.

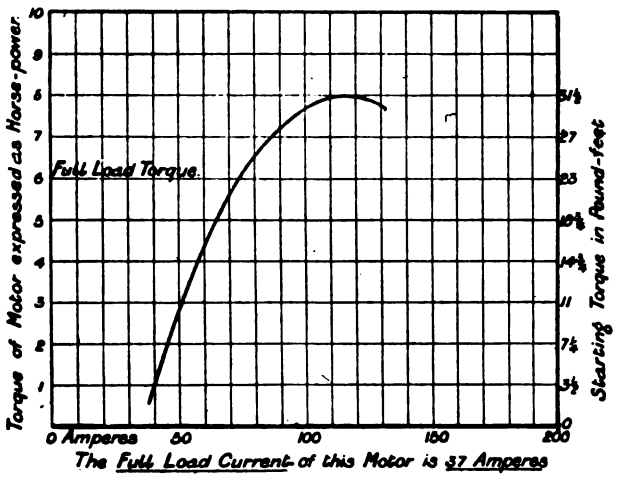

FIG. 11.

Design (*a*) has been evolved in order to conform to the ideas of many station engineers in this country. Design (*c*) represents the normal winding, while design (*b*) is frequently asked for. The starting torque with the standard stampings is determined purely by the number of turns of the starting coils and the permissible current; this torque can be arranged to have a value equal to two or three times the full-load running torque if enough current is given to the starting coils, the limiting value occurring at the saturation point of the iron.

Figs. 11 and 12 illustrate the starting performance of two motors designed to fulfil conditions (*b*) and (*c*) respectively, while Fig. 13 illustrates the running performance of the motor whose starting curve is given by Fig. 11. All these curves represent the results of actual brake tests, and many motors built have given better results than indicated here.

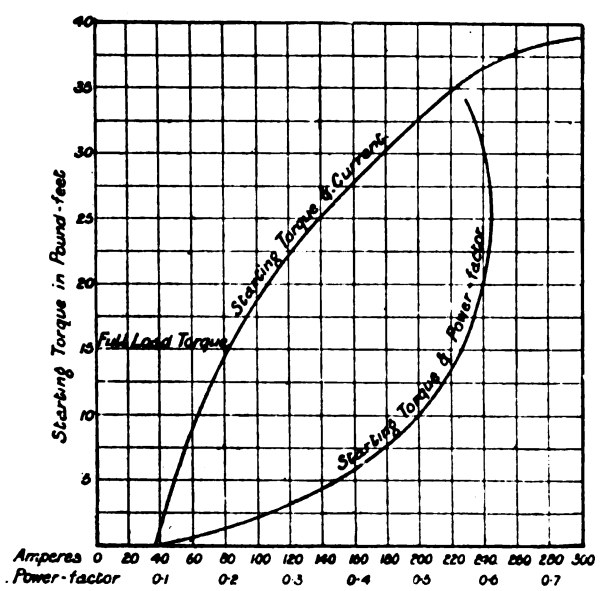

FIG. 12.

Particular attention is given in all the designs to the overload capacity of the motor, and all motors are guaranteed to stand a 25 per cent. overload for one hour. The small overload capacity (varying from 0 to 10 per cent.) found with the alternating-current motors hitherto used has been one of their worst features, as for most work it is impossible to fix the amount of power required so exactly as this, with the result that the motors installed are invariably too large and costly for the work they have to do. This reacts on consumer and supply company alike: the former has to pay for a larger motor than he wants, which will be working on the average at low efficiency, while the latter most of the time is supplying an underloaded motor

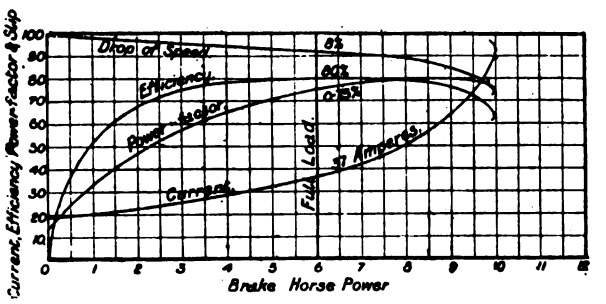

FIG. 13.

having a low power factor. The author would here like to make an exception in favour of the Wenström motor, whose overload capacity (as found with examples tested by him) is everything that can be desired.

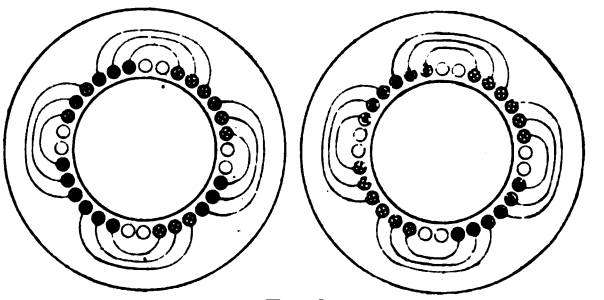

FIG. 14.

The results obtained with the Heyland motors for circuits of 80 and 100 cycles are not quite so good as those given above with regard to starting torque. That is to say, these high

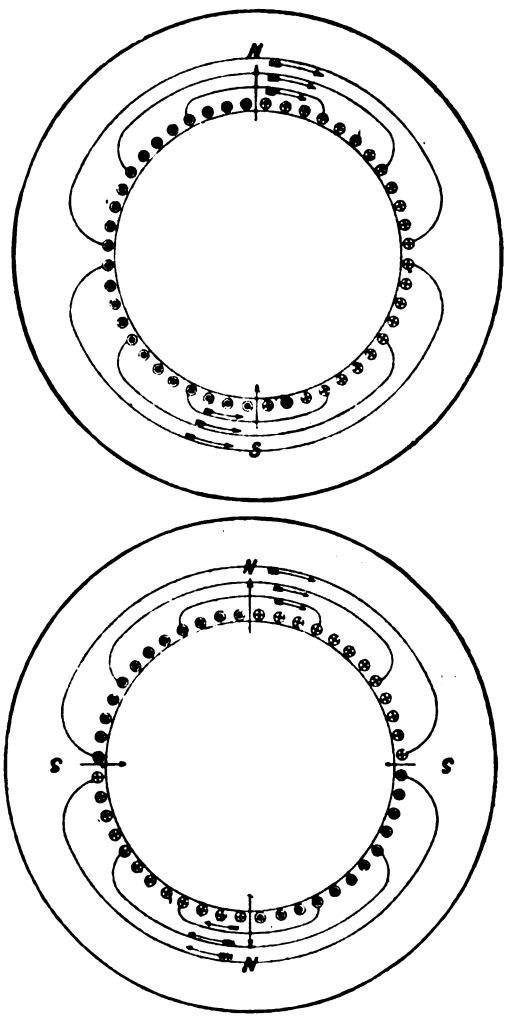

FIG. 15.

frequency motors as built up to the present take a relatively greater current for a given value of starting torque, the values being—(*a*) when starting without load, current is equal to the

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

full-load current; (*b*) starting with half the full-load torque, the current is 1½ times the full-load current; (*c*) starting with full-load torque, the current consumption is 2½ to 3 times the full-load current. The increased values of current consumption are of course due to the larger number of poles necessary to bring the speed to a reasonable figure; particularly in small motors the number of poles has a very great effect on the amount of magnetic leakage with a given design. As, however, the Heyland motors are not yet fully standardised for 80 and 100 cycles, the designers hope to effect considerable improvements within the next few months in the direction of reducing the current for a given value of starting torque.

Before leaving the subject of these motors, the author would like to draw attention to an exceedingly neat method Mr. Heyland has devised for regulating the speed of induction motors, single and polyphase. As is well known, there are two principal ways of altering the speed of such motors, the supply frequency being constant. The method of "tandem parallel control" for two motors while excellent theoretically, is hardly likely to come into commercial use at present on account of the great complication involved, and because of the bad conditions under which the motors have to work. The first is by rheostatic control, a non-inductive regulating resistance being in circuit with the rotor windings, while the stator windings are connected

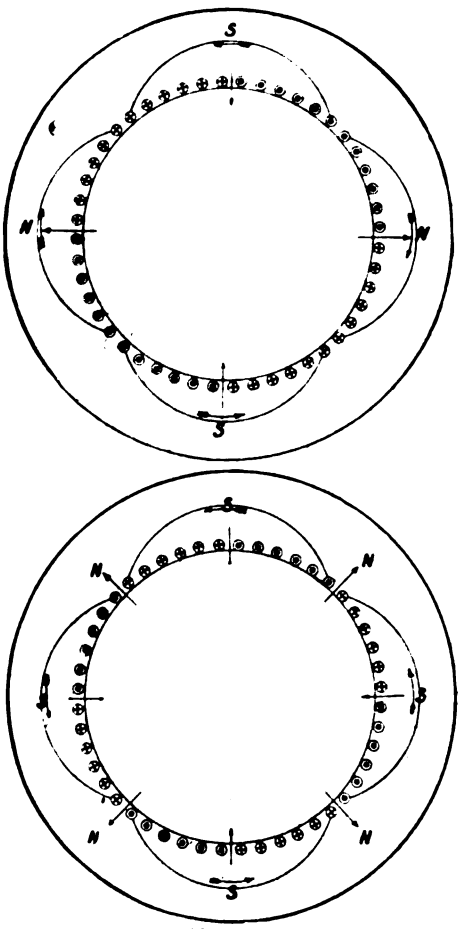

FIG. 16.

directly to the mains; the second is by altering the number of stator poles by means of a suitable controller, together with those of the rotor, unless the latter is of the "squirrel-cage" type. Here the motor is wound for the maximum number of poles, and when it becomes necessary to pass from a greater to a less pole number, in order to get increased speed, the windings on some of the poles are reversed, thus producing fewer poles, which are in consequence much broader. For instance, in order to double the speed, half the poles have their windings reversed, the stator having now half the number of poles, each of double the former breadth. While rheostatic control is simple and easy to use, it has the great objection of being very uneconomical. The waste of energy brought by its use is entirely analogous to that found with shunt-wound direct-current motors, with constant field excitation and a regulating resistance in the armature. The case of the induction motor is really more unfavourable, because it has been found by experience that the motor has to be rated very liberally in order to get the necessary power.

On the other hand, the method of altering the number of motor poles has two serious disadvantages. Firstly, the reduction of the number of poles causes an unfavourable distribution of the magnetic flux, a large increase of magnetic leakage, and a loss of winding space. This is of course owing to the fact that after the reversal of the appropriate coils the currents flowing down one side of these coils are neutralised by the currents in the adjacent side of the unreversed coils, as will be readily seen from Fig. 14 illustrating the single-phase case. Secondly, unless the motor has a squirrel-cage rotor, the rotor circuits become very complicated; the polarity of the rotor windings has to be changed each time in accordance with the stator polarity, which means that a large number of slip-rings have to be used, in order that this may be done. Mr. Heyland's method consists of certain winding arrangements which, when it is desired to change the number of poles, render any reversal of the rotor winding superfluous, and to a large extent obviate the drawbacks stated above in the reversal of the stator coils.

The method of winding the stator as applied to single-phase motors is illustrated in Figs. 15, 16, 17, and 18, the last figure showing how the stator coils are wound in practice. In all cases the winding is carried out for the smaller number of poles, and divided into sections, one or more of these sections being reversed to obtain a greater number of poles. Thus, for instance, in Fig. 15 the stator being wound initially for two

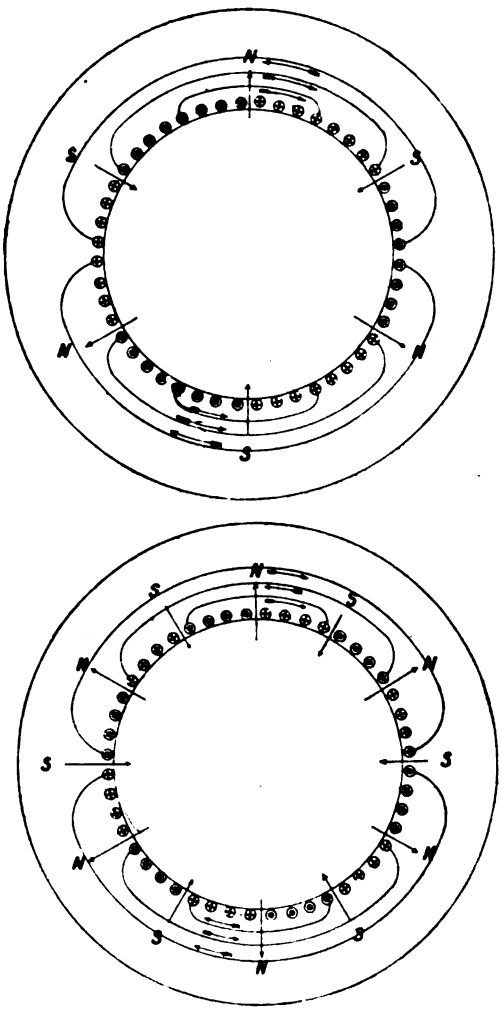

FIG. 17

poles, by reversing one of the sections of the winding a four pole stator results, as indicated, and it will be seen at a glance that there is no neutralising action between adjacent conductors, and that the distribution of magnetic flux in the air-gap will be perfectly good. Fig. 16 shows the arrangement for a four-pole to eight-pole stator, and Fig. 17 that for a six-pole to 12-pole, to which the same remarks apply. The manner of carrying out the stator winding for the last case actually employed is illustrated in Fig. 18. For polyphase motors exactly the same winding arrangements are used, applied, of course, to each phase. For these motors, if more than one change of speed is desired, the controllers get somewhat expensive, and it is, therefore, better on the whole in such cases to combine the method with rheostatic (rotor) control, the rheostat being used for the intermediate speeds only. For small motors having squirrel-cage rotors, no modification of the rotor winding is needed; but where wound rotors are employed, the general method of rotor winding is illustrated in Fig. 19, which illustrates the single-phase case for simplicity. The general principle is to so arrange the windings of each phase that they are formed of a number of sections in parallel. With a certain number of poles the E.M.F. of one section will neutralise that of another section in parallel to it, and a current will flow through the sections only when they are externally short-circuited. On the other

Digitized by Google

hand, with double the number of poles the external short-circuit is superfluous. Thus, consider Fig. 19, representing (diagrammatically) the winding for one phase of the rotor for a two-pole four-pole stator. Each phase has two sections, permanently short-circuited one on the other. At starting, the stator switch is put over to the four-pole position, and the slip-rings gradually closed through the starting resistance. So long

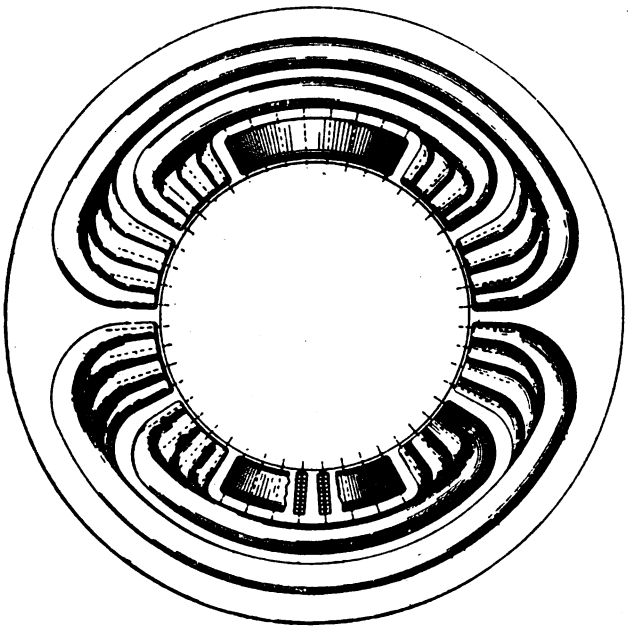

FIG. 18.

as the slip rings are open no currents flow in the rotor windings, as the induced E.M.F. has the same value in each section, and the two E.M.F.'s neutralise one another on account of the four stator poles, but the rotor currents circulate as soon as the rings are connected through the resistance. This latter is gradually cut out in the usual way as the motor comes up to speed. In changing over now to the two-pole position (if the higher speed is required) the slip-rings are not wanted, as the two sections are now in series, with the E.M.F. in the same direction, and so the rotor currents can circulate independently of the external short-circuit.

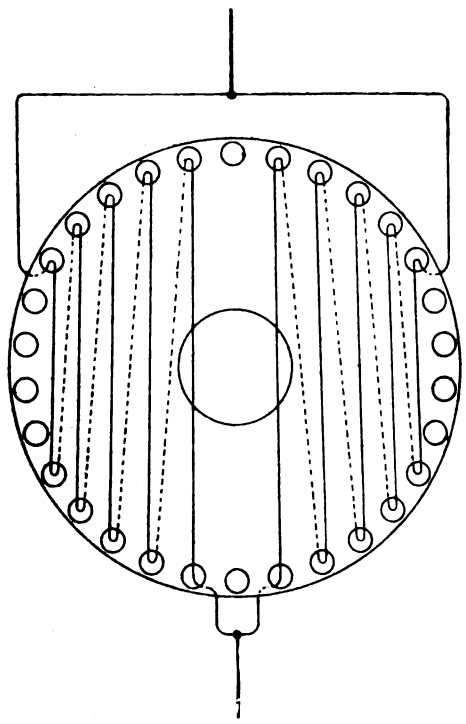

FIG. 19.

The same general arrangement is used for motors to run at more than two speeds. Here the rotor windings (per phase) can have more than two sections, these sections being wound partly to overlap one another, while still being in parallel, so that the various E.M.F.'s partly neutralise one another and partly add themselves together. With this arrangement the same rotor winding can be effectively used with a stator having several different arrangements of the poles—that is, for a motor running at several distinct speeds. For induction motors having rotors with star-connected three-phase windings, which is the practical case, only three slip-rings are required, the (second) common junction being at the three slip-rings, as usual. In the workshops of the author's firm, where many of the tools are driven by three-phase motors, the Heyland method of speed regulation is employed with great convenience. Several of the larger tools (such as planing machines and the like) are driven by independent three-phase motors wound for two speeds, the alteration of speed being effected by throwing over the reversing switch. It has been found by tests on these motors that the power factor is diminished very little by the increase in the number of poles, attaining a high value at both speeds, while the efficiency is also high at each, there being but slight loss of energy involved by the change over. At the same time, the increase of first cost with the two-speed motors is very small.

CONCLUDING REMARKS.

Although the author has dwelt at some length upon the subject of single-phase motors, it has been more on account of the technical interest attached to it than because of any belief in the present or future possibilities of single-phase systems. Regarding the Continent and the States it is not too much to say that single-phase supply is practically played out, and that engineers responsible for putting down new stations for either power or lighting consider single-phase supply systems out of date and their employment bad practice. Moreover, indications are not wanting that the present tendency in this country is to follow in the same direction. It is certain that for all those cases where continuous-current systems are out of the question every requirement can be far more successfully met by three-phase systems than by any other. It is true that certain engineers in this country hold the opinion that pressure regulation troubles are bound to occur with three-phase working (an opinion not shared by the author), but, even supposing this to be the case, the complete solution is to hand—convert to continuous current by means of rotaries, or better, by means of motor-generators. The standardisation of the above two systems, together with that of two voltages for each system—220 and 440 volts—and one frequency—50 cycles—for the supply networks, is greatly to be desired, particularly from the point of view of the motor manufacturer and the motor user. With the hope that this ideal may be eventually realised, this paper can be concluded.

LIGHT RAILWAYS.

The Light Railway Commissioners have decided to recommend the order for the construction of a light railway from Bridgwater to Cannington, Bolam Bridge, Fiddington, Stowey, and Stogursey.

An enquiry was held last week into the application for an order to construct a light railway from Norwich to Dereham. The Commissioners said they were left in the dark as to the raising of the necessary capital and the prospect of the line proving sufficiently remunerative, and therefore they could not recommend the granting of the order applied for.

An enquiry into the South Hams Light Railway scheme was held last Wednesday.

The Light Railway Commissioners have submitted to the Board of Trade an order made for the construction of a light railway in the parishes of Oakington, Westwick, and Cottenham.

The Light Railway Commissioners have submitted to the Board of Trade for confirmation an order made by them for the construction of light railways in the urban district of Aldershot.

At Thursday's meeting of the Middlesex County Council the following recommendations of the Parliamentary Committee were adopted: "That an agreement embodying the terms contained in an undertaking of Messrs. Booth and Smee, subject to the insertion of words to enable the County Council to promote such schemes as they may think necessary, be sealed with the common seal of the County Council, in a form approved of by the county solicitor; and that the Staines company be required to promote, at the cost of the company, a joint order in the name of the County Council and the company for authorising the following light railways: (1) a light railway commencing at the termination of the proposed Staines and Egham light railway line, and terminating at Hampton; (2) a light railway commencing at Staines through East Belfont to Hounslow; (3) a light railway from Hounslow through Cranford and Longford to Colnbrook; (4) a light railway from Hounslow through Heston to Southall; (5) a light railway from Twickenham through Hanworth to Kempton Park; (6) a light railway from Hounslow to Hanworth. That the county solicitor to have charge of the carriage of the order, and that the necessary notice be given in order to enable the County Council to pass, at its meeting in October, special resolutions approving of the intention to make the application."

OUR COUSINS FROM ACROSS—

Before this time next week many of our American cousins will be amongst us, and collectively and individually a hearty reception will await them. It is their due. They have led the race of progress throughout the century so far as applied electricity is concerned. Let us see. There is no necessity to enter into detail as regards dates and particulars—the broad facts must suffice. Notwithstanding the fear of Mr. Fahie's historic accuracy, there is no doubt the world of telegraphy owes much to Morse. He gave a much-needed fillip to the application—in a way, in fact, made it practical. Then Henry, so long forgotten, is now acknowledged to have been a pioneer discoverer in things magnetic. Come we to the telephone. Thick-headed, conservative, blundering, muddle-through-it-somehow John Bull did all he could by means of the men in authority and subjugated by red-tape to stop the introduction of one of the grandest and greatest of the discoveries in electricity. Talk about driving a joke into a Scotchman's head by the aid of a sledge-hammer; telephony has been driven into England's industries by the skill, energy, and pluck of our American brethren, who believed in it, and the converts their push obtained here. There is not a single paragraph in the history of telephony that redounds to the credit of England. True, the man who made it practical—the late Prof. Hughes—was long a resident amongst us and beloved by all, but even his great services, gratuitous to the world as they were, would not have aided much in the development of the industry had it not been for the business men who took the work in hand. Be it far from us to say there was no foresight among the permanent officials here. To our own knowledge there was plenty, because in the earliest of early days we discussed the whole subject with the then scientific chief. The stumbling block was elsewhere. "Move on," says the policeman, and we move on. Who, we ask, introduced electrical energy for lighting purposes? In England we played with it. Our manufacturers manufactured in driblets. Neither manufacturers nor moneyed interests tackled the question as a whole. Edison blundered along, consumed with the idea that electric lighting was not for the unit, but for the multitude. He studied the installation as a whole, not as a fortuitous concatenation of parts brought from various sources and having no earthly connection the one with the other. We did not agree with the bombast of his coadjutors, but Edison gave us the thing as a whole, each part designed to fulfil its function; and from his first installation the industry really started, has grown and developed, till, like the sparrow, it has made a home throughout the civilised world. Shall we proceed, and discuss power, distribution, and traction? Who will be found ready to take up the battle gage for England in this development as against America? What we have done is not pioneering work; it is simply the weight of circumstances and national characteristics that compel the pioneers to build and equip their factories here. From a national point of view this is a distinct gain, but it detracts nothing from the fact that someone else had to show us the

Digitized by Google

way, to produce the "go," and generally to direct our eyes and our feet in the way they should go. Many of the men who have assisted in our learning, who, in fact, have been teachers, are passing through our homeland to visit Paris. After all, they are scions of our own race, they are brothers in blood—younger as a nation; and, as is usual with the young, pushing, energetic, ambitious? They look upon England as the centre of their race, and shall we fail them in their just reward—a due appreciation of the works they have done. The very thought of backwardness is a libel upon the temperament of John Bull. His heart is still in the right place, and he will show that it is so by giving a most cordial and hearty welcome to the members of the institute from across the sea.

SPEED REGULATION.

We notice in a recent issue of the *Electrical World* a description of a patent, granted to Mr. Alexander D. Lunt, which relates to a means for equalising the speed of shafts, machines, or other rotating bodies, and is particularly applicable for preventing the hunting of synchronous motors, rotary converters, or other synchronously-operated electric machines. Briefly, the means consists of a flywheel mounted loosely on a shaft, on one side of the rim of which are electromagnets; opposite the electromagnets is a copper disc keyed to the shaft. In normal operation the friction of the flywheel on its bearing will generally be sufficient to maintain it in rotation in fixed relation to the copper disc. When, however, the speed tends to fluctuate, the flywheel, owing to its large inertia, will continue its regular rate of rotation, thereby causing a relative movement between the flywheel and its shaft, and a consequent shifting of lines of force along the disc. This latter action will result in generating electric currents in the disc, which produce a powerful braking action, and thus restrain the shaft and the parts to which it is connected from fluctuating in speed either above or below a regular rate of rotation—that is to say, the disc constitutes a closed electric circuit, which dissipates the electrical energy produced by the relative motion between itself and the flywheel carrying the electromagnets, thereby acting as a damping device, the effect of which is the more powerful the greater the tendency to deviation from normal speed. The flywheel is grooved on the rim face opposite the copper disc; windings filling these grooves are connecting with two collecting rings mounted on the hub of the flywheel, through which direct current from an exterior source is supplied to the windings. The edge of the disc furthest away from the flywheel is made of magnetic material, which serves to complete a magnetic circuit for the lines from the pole-pieces on the flywheel.

THE NEW YORK METROPOLITAN STREET RAILWAY.

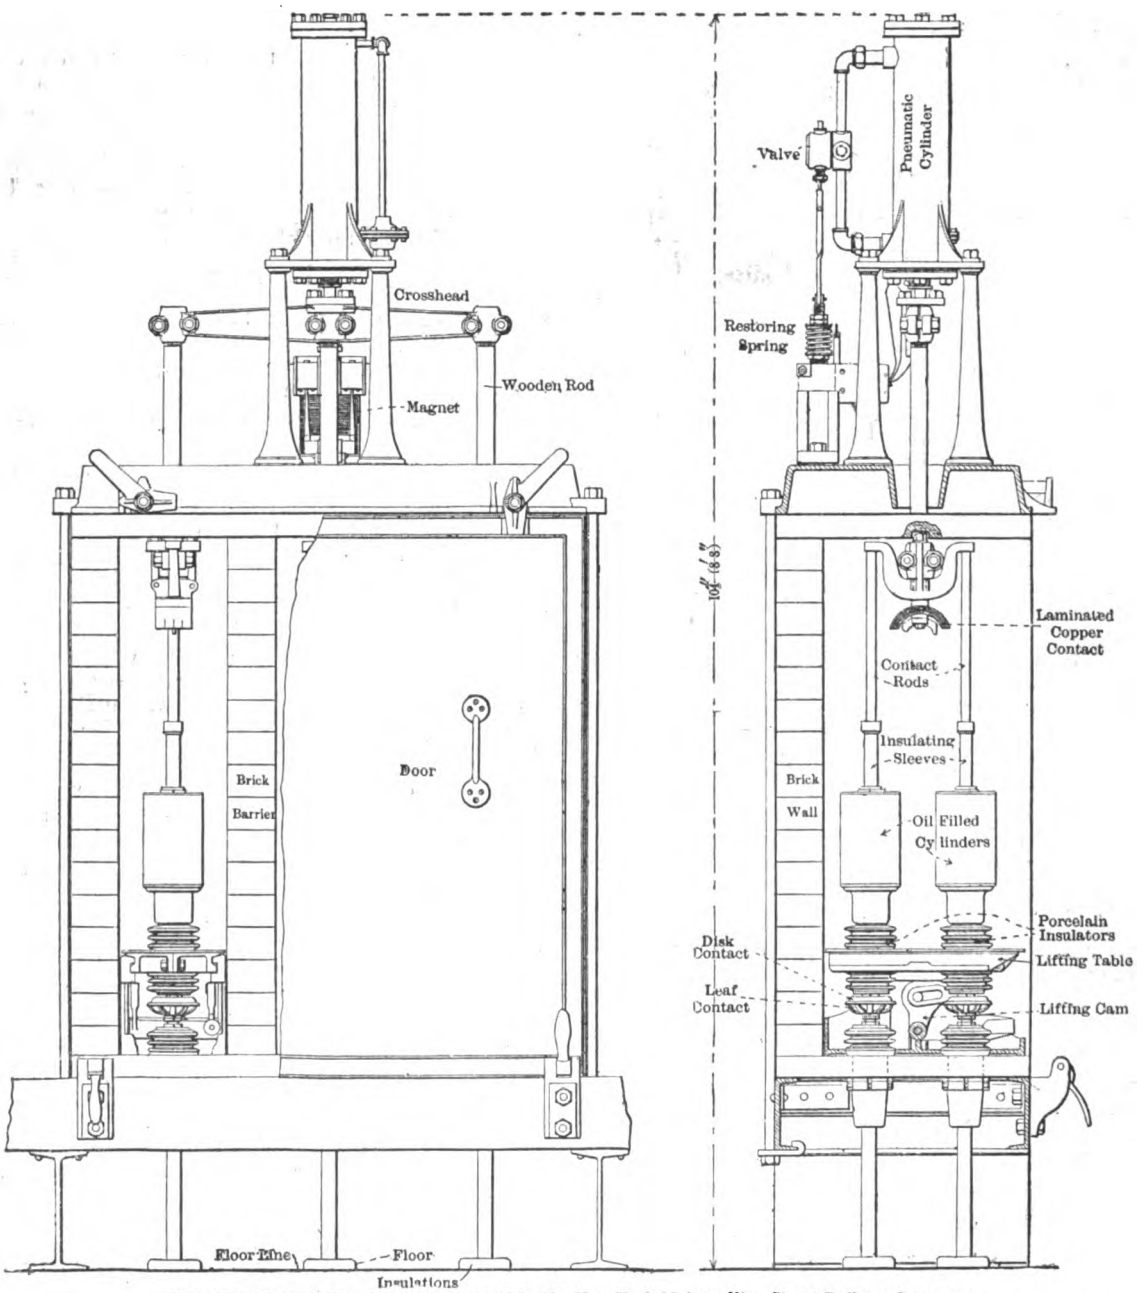
In our issue for May 11 of this year we briefly mentioned that a special feature of the high-tension circuits on the New York Metropolitan Street Railway was the employment of an improved type of oil-break switch, which in this installation takes the place of switches, circuit breakers, and fuses in low-tension work. From the *Electrical World* of New York we gather that the main power station will contain over 100 of these oil circuit breakers, all of the same size, and only differing in their capacity for carrying current. The same type of circuit breaker will also be used in the sub-stations to a very large extent. Each switch will stand on its own foundation, with its three phases in three separate cells divided by brickwork walls, and all will be operated by pneumatic power. In this new oil circuit breaker, compressed air forces a piston up or down in a vertical cylinder above the top of a brick structure enclosing the live parts. The valve controlling this cylinder is operated by the one magnet with which the device is fitted, the circuit of this magnet running from the operating switchboard. When this magnet is excited and draws its armature down, it pulls the valve into such a position as to admit air above the piston and exhaust it below, thus forcing the piston down and closing the main current contacts. If current is cut off from the magnet by any means, the valve is instantly restored by a spring into such a position as to admit air below the piston and open the contacts. The magnet is wound with two coils, one of fine and one of coarse wire, connected in series with each other. The movement of the armature moves an automatic switch, which short-circuits the high-resistance part of the winding when the armature is up, thus allowing a powerful current to pass from the constant-potential source of supply to draw the armature down with plenty of reserve force. As soon as the armature is drawn down, the increased resistance thrown in by the automatic switch reduces the flow of current through the magnet winding to an amount only sufficient to hold the armature in the down position, thus economising the current, which must be left on as long as the oil circuit breaker is closed. The magnets are supplied with current at 110 volts from exciters at the main station. The compressed air for the pneumatic cylinders is supplied by motor-driven air-pumps with automatic controllers. In the old type of oil breaker the controllers would make no move if current failed them, but in this new type of breaker the controlling switch simply opens or closes the circuit of the one magnet operating the valve, and the oil breakers will all open if the supply of current for the magnets fails. In the case of a sub-station, the failure of the motor-generators therein would, with the new type of circuit breaker, shut down the station, unless it were prevented by an assistant. The main position of the oil circuit breaker raises or lowers a metal cross-head carrying three wooden rods, which extend down into three cells, each containing the switching apparatus for one leg of the circuit. The cells being separated by brick partitions, a burn-out in one cell cannot spread to the others. As the opening of two legs breaks a three-phase circuit, an arc in one cell will not render the breaker useless. The circuit-breaking parts of the breaker consist of two brass cylinders for each phase, into the tops of which two copper rods extend from above, these two rods connecting the two cylinders together when lowered by the cross-head to which they are attached. The two brass cylinders in each cell are respectively mounted on copper castings, to one of which is connected the incoming lead and to the other the outgoing lead of the same phase. Each cylinder is nearly filled with transil oil, and is covered by a metal cap, which carries a long insulating sleeve in stuffing box, and oil-wiper round the rod. When the three pairs of rods on one cross-head are lowered, their ends make contact with the copper castings under the oil and the circuit is closed. When the rods are lifted the circuit is broken under the oil at two points in each leg, or six points in each complete three-phase switch. The range of movement of the cross-head is a foot, giving in each leg an opening of nearly 2ft., and thus in series with each phase an opening of nearly 4ft.

The enclosure of the cans containing the oil gives a certain amount of compression to suppress arcing if the drowning of the arc by the oil is alone not sufficient. Although the long insulating stuffing box does not fit tightly around the rod, any arc which might form on breaking the circuit causes such a sudden expansion of the oil that the air above it in the can does not find time to escape, thus preventing the arc from blowing the oil away from its path. The brass cans are lined inside with fibre to prevent the arc from jumping from the rod to the metal of the can if it is drawn up through the oil to its surface. As to the more detailed construction of the apparatus, on the lower end of each copper rod is screwed a removable blunt-pointed brass tip. When the rod is lowered, it passes through two tubes or sleeves, each split into four segments, which surround the rod tightly and are forced against it by springs. Of

Digitized by Google

the two split sleeves, the lower one is made of copper and the upper one of brass. When the rod is drawn up the final opening is between the brass sleeve and the brass tip, thus making use of the non-arcing metal principle. When the brass tip leaves the brass the segments of the latter close in and rub against the tapering end of the rod, transferring the final break and any pitting that may occur to the tapered end of the rod, where it will not scratch and injure the surface of the copper sleeve the next time the rod goes down.

The piston and cross-head of the circuit breaker are prevented from falling and thus closing the circuit, if the air fails, by a hook or latch, which catches the cross-head in its raised position. When air is turned on above the piston it is led by a branch pipe to a small auxiliary cylinder, this auxiliary cylinder releasing the latch and allowing the cross-head to fall, thus promptly closing the circuit. Each lead into and out from the oil-cylinders comes up through the floor and terminates in an inverted crown of copper leaves, termed in our illustration a leaf contact. Normally there rests upon each of these leaf contacts a disc contact fixed to the copper casting which forms the bottom of one of the oil-filled cylinders or cans. The two copper castings in each cell are fastened to corrugated porcelain insulators mounted on a small table which can be raised or lowered. When raised, the disc contact is lifted away from the leaf contact, giving an air opening in the circuit each side of the breaker in each phase. This allows for repairs or adjustment of the live parts of the breaker.



Elevation of an Oil Circuit-Breaker as used by the New York Metropolitan Street Railway Company.

These oil circuit breakers are made in two capacities, the larger rated at 800 amperes and used for the generators and for groups of feeders, the smaller with a capacity of 300 amperes for the feeders and for all of the high-tension work in the sub-stations. The breakers are of the same size, the difference between them being that the one with the larger capacity has an auxiliary or primary contact in air made by means of a brush of copper leaves bridging from the top of one of the brass cans to the top of the other of the same phase, and thus shunting the contacts under the oil. Normally this primary contact in air carries the greater part of the current, but when the breaker is opened the primary contact is broken first, throwing the whole load on the rods and their surrounding sleeves under the oil. A good idea of the construction of these circuit breakers can be gathered from the illustrations given.

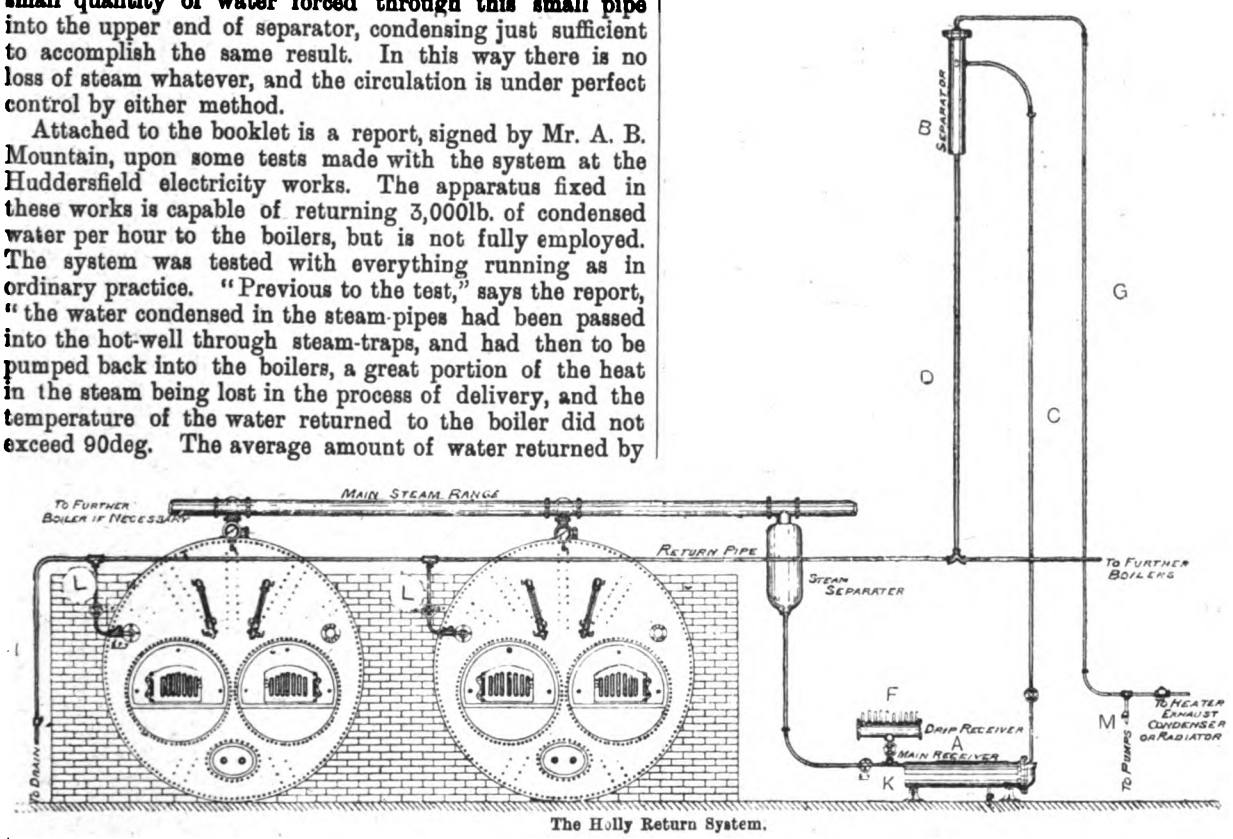
THE HOLLY GRAVITY-RETURN SYSTEM.

We have received from the makers, Messrs. Wm. Whiteley and Sons, Limited, Prospect Ironworks, Lockwood, Huddersfield, a very nicely illustrated booklet describing the Holly gravity-return system. The accompanying diagram and description taken from the booklet will explain the system: The drip receiver, F, is a vessel for collecting drips from all parts of a plant, and should be placed below the lowest point to be drained. From

Digitized by Google

this receiver it flows into the main receiver, A, through a specially designed suction tee, K. The forcing end of the suction tee is connected to one or more adjacent steam separators I, and this condensation is also delivered into the main receiver, under the initial or boiler pressure. The whole is then swept up the riser pipe, C, in sections or finely-divided particles (due to the special discharge head on one end of main receiver) into the separator, B, where it falls into the return pipe, D, which is capable of feeding any number of boilers. The water, in its upward flight, is carried with the steam that is required to maintain the circulation, and occupies some vertical position above the water-line of boilers, in the return pipe, D, where the included column, plus the pressure in separator, will weigh more than the pressure carried in the boiler, thus producing a continuous feed to the boilers at practically boiler temperature. The object of the small pipe, G, and reducing valve, R V, is to place the engineer-in-charge in absolute control of the circulation between the receiver and separator; it permits an atmospheric escape of steam just sufficient to ensure this result, and it may be adjusted for varying quantities; this escape is so very small as to be infinitesimal, and in nearly all cases it is utilised in the heater, condenser, hot-water tank, or in heating by radiation. Should there be no convenient method of utilising the steam passing though valve, R V, the pipe is connected to the feed pump discharge, M, and a small quantity of water forced through this small pipe into the upper end of separator, condensing just sufficient to accomplish the same result. In this way there is no loss of steam whatever, and the circulation is under perfect control by either method.

Attached to the booklet is a report, signed by Mr. A. B. Mountain, upon some tests made with the system at the Huddersfield electricity works. The apparatus fixed in these works is capable of returning 3,000lb. of condensed water per hour to the boilers, but is not fully employed. The system was tested with everything running as in ordinary practice. "Previous to the test," says the report, "the water condensed in the steam-pipes had been passed into the hot-well through steam-traps, and had then to be pumped back into the boilers, a great portion of the heat in the steam being lost in the process of delivery, and the temperature of the water returned to the boiler did not exceed 90deg. The average amount of water returned by



The Holly Return System.

the system per hour was 384lb. The temperature of condensed water returned to the boilers was 363deg. The heat saved per pound of water per hour was therefore 273 heat units. The heat emitted by a pound of coal in evaporating 7lb. of water equals 6,842·5 heat units per hour. Heat saved per year therefore equals 918,328,320 heat units, representing 59 9 tons of coal, which at 12s. per ton equals a total saving by the 'Holly system" of £35. 18s. 9d. The advantage of the system is that it is not necessary for a man to open any taps connected with the steam-pipes previous to admitting steam, and there is no chance of the steam-piping becoming waterlogged. The water can only flow from the steam-pipes in one direction, and in the event of a steam-pipe being shut off for repairs the check valves upon the system automatically stop the return. The cost of the system is about £100, and the saving shown by the foregoing tests amounts to about 36 per cent. on this outlay, but as the test was made during the hot weather, it is only fair to assume that the saving would be almost double during the winter. The cost of working the system is difficult to ascertain, but the small quantity of steam required to be condensed in the top separator, which creates the vacuum and causes the automatic working of the apparatus, should undoubtedly be covered by 10 tons of coal per annum."

It may be mentioned, in conclusion, that the system has found extensive application in America.

QUESTIONS AND ANSWERS.

Questions.

293. Is it possible to wind the shunt and series winding of a compound dynamo on separate formers in such wise that it shall be possible to remove either the shunt or series field winding without disturbing the other?—E. R.

294. Is there any electrical device that will automatically keep the pressure constant with varying loads on battery-regulating cells? If so, describe and illustrate same.—F. L. Watson.

Answers.

Question No. 287.—Give particulars and explain any arrangement for the abatement of smoke from station chimneys you may have had practical experience with, and state result.

Best Answer to No. 287 *(awarded* 10*s.)*.—Among several types of smoke-consuming furnace that have come under the writer's notice, the three here described produced the best results. Fig. 1 shows part of the brickwork setting of a well-known combination of Lancashire and marine type boiler. In this boiler the end plates act as tube plates for a large number of tubes, which at the front end terminate

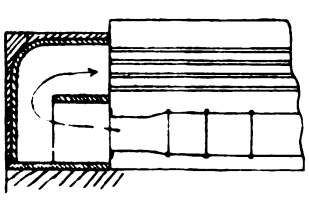


Fig. 1.

in a smoke chamber, from which the gases are led to the chimney through two external flues. The shell is set in the brickwork in such a way that the main internal flues end in a combustion chamber lined with firebrick and provided with deflecting arches. When the boiler is in full

Digitized by Google

work this deflecting chamber becomes practically white hot, so that any free carbon and unburnt gases passing from the internal flues through the chamber up to the return tubes stand a good chance of thorough combustion. The writer has seen a boiler of this class fired with long flaming bituminous coal, the amount of smoke escaping being very small.

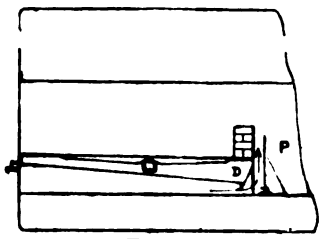

FIG. 2.

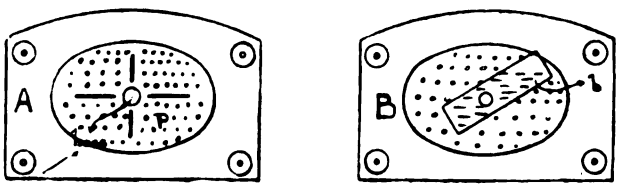
Fig. 2 shows another arrangement. In this case air is admitted from the ashpit through a small door, D, underneath the bridge. This door is connected by means of a bar and lever to the firedoor, so that on opening for charging the door, D, is also opened. Air enters, and is deflected upwards by means of the baffle-plate, P, and is thus mixed with the unburnt gases, etc. The door is gradually closed by moving the connecting bar back notch by notch, the closing of the firedoor having no effect on the back stroke. This arrangement was fairly good from a smoke-consuming point of view, but the presence of a body of comparatively cold air in the flues just beyond the bridge was not conducive to the well-being of the boiler. Another disadvantage of this arrangement is the fact that it is not automatic, though this defect might be overcome by the use of a weighted door and suitably arranged pulleys and balance weights. Fig. 3 shows the third and most satisfactory arrangement. Air is here admitted through the furnace doors, and the supply automatically reduced and finally cut off after every charge.



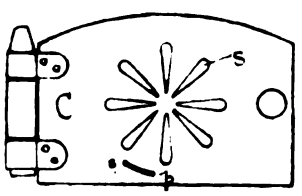


FIG. 3.

At A is shown the perforated back plate of furnace door, the outer cover being removed. Between this back plate and outer cover is mounted an oblong cast-iron box (shown at B) in such a way that it is free to swing in a vertical plane. Fixed to this box is a circular plate (not shown), with slots coinciding with those in the outer cover of door shown at C. The distance through which the box and attached shutter plate can swing in either direction is controlled by the length of the radial slot, S, through which a pin projects from the shutter plate immediately behind. The box, *b*, is filled with mercury up to such a level that when the furnace door is open, and consequently cold, the weight of mercury swings the box and shutter plate over until the pin, *p*, reaches the lower end of slot, S. The slots, S, in outer cover are now fully open. The charge is now thrown on and door closed. Air enters freely through slots, S, and is distributed through perforations in plate, P. Heat from the fire causes the mercury in the box to expand. As its centre of gravity alters, the box swings over, gradually closing the slots, S, by means of the shutter plate which moves with it. This arrangement is simple, and not likely to get out of order, neither is the regularity of its action dependent upon the caprices of the fireman.

The writer has, however, come to the conclusion that a good mechanical coking stoker, the absence of necessity for forcing the boilers, and the services of a good fireman are the most satisfactory means of preventing smoke troubles.—P. S. T.

Answer to No. 287 (*awarded* 5*s.*).—The production of smoke is caused by the mixing of particles of unburnt carbon with the gases of combustion from the furnaces. The reason that these particles have been allowed to escape may be either lack of oxygen wherewith to combine, or else too low a temperature to effect the combination. Methods of smoke prevention based on both of the above reasons have been brought forward by boiler-makers and furnace-builders. One of the simplest device is to cut an opening in the firedoor above the level of the fire, and to cover this opening with a door so arranged that the amount of opening can be regulated. By this means a current of air flows over the glowing coal, mixing with the particles of carbon, and if the temperature of the mixture be raised sufficiently by contact with the fire the carbon will be consumed. The objection to this method is that by admitting a quantity of cold air the temperature of the furnace gases is lowered, and the boiler does not work so economically as before. It may be noted, by the way, that smokeless combustion is by no means synonymous with highest economical consumption of fuel. Another method of securing sufficient air to ensure complete combustion is to force the air through the firebars, either by forced or induced draught. There are losses of power due either to mechanical driving of fans (as in the case of induced draught) or direct consumption of steam, as in the Meldrum or Bennis systems of forced draught. Provided, however, that careful attention to firebars and furnace linings be given, on account of the high temperatures attained by these methods, these systems answer well. It is also claimed by makers of this type of furnace that the passage of the cold air through the firebars preserves these. I have noticed, however, that with some classes of coal extensive clinkering is sure to occur with forced draught, giving a lot of trouble with firebars unless they are constantly moving. It may also be pointed out that the failure of a fan in the main flue would be a very awkward occurrence at any time when the boilers were particularly required.

A "coking" stoker is a very good device for prevention of smoke. In this the "green" fuel is placed at the front of the fire, and gradually worked back to an ashpit at the back of the firebars. By this means the combustible elements of the fuel are given off in regular sequence—first, the light volatile gases, together with any moisture in the fuel; then the heavier hydrocarbons, succeeded by solid carbon. The coal is now reduced to a glowing surface of coke having very little free carbon in it, and being at a very high temperature. The combustible elements, together with air, sweep over this incandescent surface, and the exceedingly high temperature, added to their own temperature, ignites them and ensures complete combustion. This is probably one of the most satisfactory ways of dealing with fuel rich in free carbon. An analogous method for use in ordinary furnaces of dealing with "rich" coals, is to mix them with coke or anthracite. A higher state of incandescence is thus produced, and the particles of carbon in the rich coal burnt. I have, however, noticed that it is a mistake to attempt to blend large, lumpy coal with anthracite slack or small coke, as the fire burns unevenly into holes. Where a good draught is available the burning of anthracite coal is a preventive of smoke nuisance, as this coal gives a bright, clear fire of great heat, consuming its own smoke and producing very little clinker. The only drawback is that it is a very difficult coal to start a fire with, and will not burn well unless with a strong draught. J. A. S.

Question No. 288.—What current density per square inch is it usual to allow in best engineering practice in switch contacts of the following types: (1) laminated contacts constructed of hard-rolled sheet copper; (2) spring contacts

Digitized by Google

in which the contact surfaces are machined, and the only material used is cast brass—*i.e.*, such as those used in the Bates fuse and Brush trigger switch; (3) flat cast-brass machined contacts, which can be held together under considerable pressure by a nut or set screw. Give sketches.

Best Answer to No. 288 (*awarded* 10*s.*).—The term 'current density" here is evidently to be understood as the surface density at the points of contact of switches, etc. The ratio between the surface density and the cross-sectional density in a switch, for instance, is affected by several considerations, none being more important, in the writer's opinion, than the quality of workmanship the manufacturer is able to command. It is also affected by the different conditions enumerated in the questions (1), (2), and (3). Taking the first case of a switch with laminated closer of hard-rolled sheet copper, with probably gunmetal contacts, it is good practice to work at 400 amperes per square inch. This density, with accurate machinery and fitting, should be ample. It will be noticed that it is advantageous to make the angle θ, in Fig. 1, as small as possible compatible with good design, as in switches of this type the difficulty is to get the required surface area while not wasting any metal in the cross-section. When foliated copper is used, as in the Crompton "S" switch, the density may with safety be raised to 500 amperes per square inch.

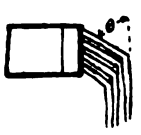

FIG 1.

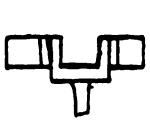

FIG 2.

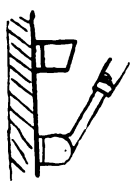

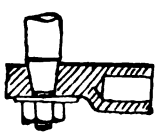

FIG 3.

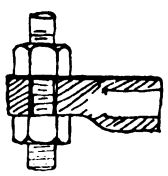

FIG 4.

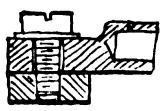

FIG 5.

In the second case, we have a switch differing from the first in two ways. The method of making contact—viz., one machined surface rubbing on another—is obviously not so good, owing to the fact that it requires very skilful fitting to make the surfaces bear evenly. That they very often do not do so (see Fig. 2) will be made evident upon examination of some switches of the knife or chopper type. Also the conducting metal is cast brass as against copper. While copper is run by several large electrical firms at from 880 to 1,000 amperes per square inch, brass will only carry 250 to 300 amperes for the same area. Introducing, then, the factor of safety as in the first case, the surface density is generally taken at about 160 amperes per square inch.

The third case presumably applies to the connecting of cable sockets and the like to switch contacts or 'bus bars, and the features differ materially from the first and second cases. Two methods ordinarily used in making these connections which are maintained under pressure are shown in Figs. 3 and 4. In Fig. 3 the bearing surface is part of a cone, the cable socket being accurately seamed to fit the coned stem. The angle of coning is generally about 9deg. to 12deg., or a decrease of ·15in. to ·2in. of diameter per inch of length. In Fig. 4 the two sides of the socket are relied on for bearing surface against two hexagon nuts, and in Fig. 5 on one side held down to a 'bus bar by means of a set screw. The efficiency of the contacts in Figs. 3, 4, and 5 are greatly improved by turning both surfaces, which, when pressure is applied, become practically a good soldered joint. A feature which enters here into the consideration as to what surface density it is permissible to use is the mass of copper in proximity to the joint, which has the effect of conducting away a great proportion of any heat generated, and this, in conjunction with the above-mentioned, would make it quite safe to work at 200 amperes per square inch.—E. J. EVANS.

LONDON COUNTY COUNCIL TRAMWAYS.

At Tuesday's meeting of the London County Council the following report of the Highways Committee recommending large extensions to the tramway system of London was discussed and adopted. The recommendations of the Improvements Committee in regard to the street widenings were also adopted:

1. We have had under consideration the question of what further extensions and doublings are desirable in connection with (*a*) the Council's northern tramways, leased to the North Metropolitan Tramways Company; and (*b*) the undertaking on the south side of the Thames, known as the London County Council tramways, and worked by the Council itself; and what new lines not to be immediately connected with either system should be constructed. We now, as the result of our deliberations, submit proposals for new tramways, for the construction of which we think the Council should seek for powers by a Bill to be introduced in the next session of Parliament. We have, in accordance with standing order No. 352, consulted the solicitor, who has expressed the opinion that the Council has power to promote such legislation. We regret that owing to the time which we have necessarily had to devote to the consideration of this very important matter, and in connection therewith the time taken up by our negotiations with the Improvements Committee as to the street widenings involved by the various proposals, we have been unable to comply with the standing order No. 350, which requires that proposals for legislation shall be submitted to the Council not later than at the first meeting in June; and in the circumstances, we must ask the Council to suspend the standing orders in order that our proposals may be considered.

Estimates of Cost.—Our proposals, which are dealt with seriatim in this report, are for the construction of new tramways of a total length of about 16¼ miles on the *north* side of the Thames, at an estimated cost, for the tramways and necessary paving and other works in connection therewith, of about £461,300, and for street widenings of about £544,360; while, as regards the *south* side of the Thames, the total length of tramways is about 12 miles, the cost of construction and paving works is estimated at about £374,500, and of the street widenings at about £449,400. As regards the street widenings, we have, as stated above, been in consultation with the Improvements Committee; and we understand that it proposes to recommend (*a*) that the Council do contribute, out of the funds applicable to improvements, sums amounting in the aggregate to £355,006, and (*b*) that the road authorities concerned shall contribute sums amounting in all to £326,688. The remainder of the cost of the street widenings, £312,067, we propose shall be charged to the tramways account as part of the first cost of the several tramways. These three amounts do not, as will be seen by the paragraph relative to scheme *xiv.*, make up the whole cost of the street widenings. The estimates of the cost in the case of each of the proposals is stated in this report.

Systems of Traction to be Adopted.—We propose that those of the new lines which will be intimately connected with the Council's (northern) tramways (leased until Midsummer, 1910, to the North Metropolitan Tramways Company) shall, with one exception hereinafter referred to, be constructed for horse traction, unless in the meantime effect shall have been given to the provisions in the company's lease relating to the conversion of the system from horse to electrical traction. The estimates provide, however, for rails of sufficient weight to permit of their being used for electrical traction when that system shall have been adopted on these tramways. The exception is the tramway (*i.*) in the Archway-road, which will practically be an extension from the Council's tramway terminus in that road to the county boundary, and will probably be joined with the light railways which the Middlesex County Council is seeking powers to construct from that point to Finchley and beyond. As the Middlesex Council proposes to adopt a system of electrical traction for its light railways, we think it expedient that the Council's new Archway-road line should be constructed for a similar system of traction. Those of the new lines which will be intimately connected with the London County Council tramways undertaking, or which, being for the present detached from either undertaking, could be worked by the Council independently of any other system of tramways, we propose shall be constructed for some system of electrical traction. The estimates which we submit of the cost of the several lines have been based on the assumption that in each case, as regards traction, the course proper to each line as indicated above will be followed.

Cartoon Plan and Hand-Maps, showing the Proposals and the Indicating Numbers.—We have given instructions for a cartoon plan and hand-maps to be prepared, showing the various proposals which we submit for the Council's consideration, and which are indicated on the cartoon and maps by the same numbers as are used for that purpose in this report. We think

Digitized by Google

these will be of assistance to members of the Council when they are considering our various proposals.

Suggestions of Road Authorities and Others for New Tramways. We requested the various road authorities in London to make suggestions as to what extensions of, or junctions between, the tramways in their respective districts were in their opinion desirable; and those made we have considered, together with suggestions upon the subject from the North Metropolitan Tramways Company (the Council's lessee), and from the Council's responsible officials. As regards those of the engineer and of the company, we have ascertained as far as possible the views of the respective road authorities concerned, and these are stated below. We submit, for the information of the Council, the following brief statement of the reasons which in our opinion render desirable the various extensions and junctions, for the construction of which we propose that the Council should seek powers.

PROPOSED NEW TRAMWAYS—NORTH OF THE THAMES.

(*i.*) *Archway Tavern* (existing lines) to the *County Boundary*; length, 3 furlongs.—This line is the subject of an application of the Council, now before the Light Railway Commissioners, for powers to construct it as a light railway. In view, however, of the possibility that this application may not be granted, we think that the line should be included in the Tramways Bill of next session. Powers for the necessary street widenings are included in the Council's Improvements Bill now before Parliament. This line would form the link between the Council's (northern) tramways and the light railways beyond the county boundary, for the construction of which the Middlesex Council is seeking powers. The Middlesex Council proposes to use a system of electrical traction on its light railways, and we think that this short piece of line should be constructed for a similar mode of traction. The cost of construction of the line for electrical traction is about £8,400; and current for working it could be obtained (*a*) from the Vestry's electric light station, which is within a short distance, or (*b*) by arrangement with the Middlesex Council.

(*ii.*) *Seven Sisters-road* (existing lines), *viâ* Amhurst-park to *Upper Clapton-road* (existing lines—length, 5 furlongs 1 chain). This proposal was included in the Council's Tramways Bill of this year, but was withdrawn owing to the refusal of the Vestry of Hackney, one of the road authorities concerned, to assent to the construction of the tramways; while the other road authority, the Vestry of Stoke Newington, gave its consent subject to the Council agreeing to pave the whole width of the carriageway, and it has again asked for the same concession as a condition of its consent. We do not, however, propose that this concession should be made, as otherwise there is little doubt that other road authorities would make claims for similar concessions, and we propose to inform the Vestry. Under the Tramways Act, 1870, the obligation laid upon the Council as a tramway owner is only to maintain the road between the tramway rails and for 18in. beyond the outer rail on each side, and we do not think that the Council would be justified, except in very special circumstances, in agreeing to do anything more than the Act requires. In the hope that the road authorities concerned may eventually consent to the construction of the line, we have included the proposal amongst the others. No street widenings will be required, and the estimated cost of construction of the tramways, for horse traction, is £11,250.

(*iii.*) *Mildmay Park* (existing lines) westwards to *Balls Pond-road* (existing lines); length, 2 chains.—This is a short junction line, suggested by the engineer after consultation with the managing director of the North Metropolitan Tramways Company, as an alternative to a proposal of the Vestry of Islington for the construction of tramways, which would involve expensive street widenings, along Newington Green-road. The junction would be a great convenience to the tramway traffic, and the company considers that the formation of this junction would be of greater benefit than the construction of the line proposed by the Vestry. The Vestry does not consider the alternative proposal entirely satisfactory, but we think that, having regard to the fact that the alternative would involve no street widenings, it should be adopted in preference to the other. The estimated cost of the construction of this short piece of line, for horse traction, is about £400.

(*iv.*) *Harlesden* (near the county boundary), *viâ* Scrubbs-lane, Wood-lane, Shepherd's Bush-road, Brook Green-road, and Fulham Palace-road to *Putney Bridge*; length, 4 miles 7 furlongs.—This line, which was suggested by the engineer, we consider would be very valuable from a traffic point of view, as providing much-needed and urgently required means of transit; and we are informed that the Housing, etc., Committee is of opinion that the line would be of great assistance from the housing point of view. It would start in a thinly-populated district, which is, however, ripe for building, and there is a great probability that if the proposed tramways were constructed, and means thus provided for communication with the business parts of Fulham and Hammersmith, many persons to whom the tramways would be a boon would reside near to the tramways starting-point, just within the county boundary. The construction of a double line along the route indicated would necessitate certain street widenings, the estimated cost of which is £139,250. The Improvements Committee is prepared to recommend the Council to carry out these widenings, subject to one-third of the cost being borne by the road authorities concerned—namely, the Vestries of Fulham and Hammersmith, one-third being charged to the account of the improvement, and the remaining third to the tramways account, and with this proposal we concur. The Improvements Committee is in communication with these Vestries, but has not yet received their final decisions with reference to the matter. The cost of the construction of the tramways for electrical traction is estimated at £146,250, and for horse traction at £73,050. These tramways could be worked by the Council in connection with other extensions of its system.

(*v.*) *Uxbridge-road* (near the railway station), *viâ* Richmond-road, Netherwood-road, and Westwick-gardens, to *Shepherd's Bush-road*; length, 3 furlongs.—This suggestion is also made by the engineer. This short piece of line would form a useful adjunct to the tramways, *iv.*, at Shepherd's Bush-road, of which the line would, indeed, practically form part. We are advised that these tramways would probably be remunerative, and would also be of great convenience to the public. Some small street widenings would have to be carried out, the estimated cost of which is £8,700. In this instance the Improvements Committee does not see its way to recommend the Council to contribute out of improvements funds; so that the whole cost will have to be borne by the tramways account, unless the Vestry of Hammersmith, with which that committee is in communication, can be induced to make a contribution. The cost of the construction of the line for electrical traction is estimated at £11,250, and for horse traction at £5,500.

(*vi.*) *Brook-green-road*, at its intersection with Hammersmith-broadway, *viâ* that thoroughfare to the London United Tramways at *Glenthorne-road*; length, 5 chains.—This was proposed by the engineer as a connecting link between the proposed tramways, *iv.*, and the London United Tramways. The Vestry of Hammersmith, the road authority concerned, has not yet expressed any definite opinion with regard to the proposal. We propose that this line, in common with *iv.* with which it will be in connection, shall be constructed for electrical traction, the estimated cost being £2,000. No street widenings will be necessary, as the road is sufficiently wide for a double line of tramways.

(*vii.*) *Victoria-embankment* (Blackfriars end), *viâ* the Embankment, Victoria-street, Buckingham Palace-road, Commercial-road, Bridge-road, and the Chelsea-embankment to near *Battersea Bridge*; length, 4 miles 3 furlongs.—It is suggested that the line should be continued along World's End-passage to and over Putney Bridge, and this proposal is dealt with in a separate paragraph. The Council is the road authority as regards the Victoria-embankment, and therefore, although part of the tramways would be situated in the Strand district and the parish of St. Martin-in-the-Fields, the consent of the Vestry and the District Board would not be necessary. The road authorities whose consent would have to be obtained are the Vestries of St. Margaret and St. John, Westminster, St. George, Hanover-square, and Chelsea. The first-named Vestry is not hostile to the scheme, and may probably assent to it; the Vestry of St. George has signified its approval, and no decision has yet been come to by the Vestry of Chelsea. We are of opinion that these tramways, if constructed, would prove of great benefit to the travelling public, as they would afford means of communication in almost a direct line between Chelsea on the one hand and the City on the other. There is little doubt that, for this reason, the tramways would prove a profitable investment for the Council, as well as providing much-needed and efficient facilities for locomotion. No street widenings will be needed in connection with this line, the estimated cost of the construction of which for electrical traction is £132,000.

(*viii.*) *Battersea Bridge*, *viâ* Chelsea-embankment, World's End-passage, King's-road, New King's-road, and Putney Bridge-approach, *to* and *over Putney Bridge*; length, 2 miles 1 furlong 2 chains.—The line, which is in continuation of *vii.*, would involve the widening of the whole length of World's End-passage, and also widenings in King's-road and New King's-road, the cost of which is estimated at £396,410. The road authorities concerned are the Vestries of Chelsea and Fulham. The Vestry of Chelsea has not yet decided whether it will contribute or not, but the Vestry of Fulham states that it does not consider that the expenditure for widenings would be of benefit to the parish. The Improvements Committee is prepared to recommend the Council to undertake the street widenings, and to pay out of improvement funds one-third of the cost, provided that the two road authorities concerned will, together, contribute another third, the remaining third being borne by the tramways account. The continuation of the tramways along the route indicated would certainly be very desirable from a traffic point of view, as the two together would form a continuous line seven miles in length along districts at present without facilities of communication, and there is little doubt

Digitized by Google

that the route would be popular and, therefore, remunerative. Having regard, however, to the large expenditure which would have to be incurred for street widenings which are desirable for other than tramways purposes, we do not think that the construction of this extension of the line *vii.* should be undertaken by the Council unless the road authorities concerned will agree to make the contributions suggested by the Improvements Committee. It is to be remembered that if the Council should obtain powers for the construction of the tramways, it is under no obligation to exercise them; and we have, therefore, included the proposal among the others. If the arrangements proposed by the Improvements Committee as regards the street widenings be adopted, £132,137 will be contributed by the Council out of the funds applicable to the improvement, and a similar sum out of the tramways account, while the remainder will be paid by the road authorities concerned. The cost of the construction of the tramways for an electrical system of traction is estimated at £65,000.

(*ix.*) *Hampstead-road* (tramways terminus), across Euston-road, and along Tottenham Court-road to *Oxford-street*; length, 5 furlongs 4 chains.—This was suggested by the engineer after no street widenings will be necessary to permit of the construction of a double line.

(*x.*) *Theobald's-road* (tramways terminus), *vid* Vernon-place, Bloomsbury-square, Hart-street, across Oxford-street, and along Shaftesbury-avenue to *Cambridge-circus*; length, 4 furlong 7 chains.—The suggestion first made by the Vestry of St. James's, Westminster, was that this line should extend to Piccadilly-circus; but the Vestry afterwards suggested that the line should, on account of the large number of places of entertainment near Piccadilly-circus, and the consequent large cab and other traffic at that point, stop short at Cambridge-circus, and this suggestion we have adopted. The St. Giles District Board, through whose district parts of the tramway would be laid, has refused consent to any tramways being constructed in its district, and the Holborn District Board has not expressed any opinion with regard to the proposal; but we think that the line would be of such value to the public that we include it among other proposals, in the hope that those bodies may be induced to assent to it. No street widening will be necessary in connection with these tramways, and the estimate of the cost of construction for horse traction is £8,800.

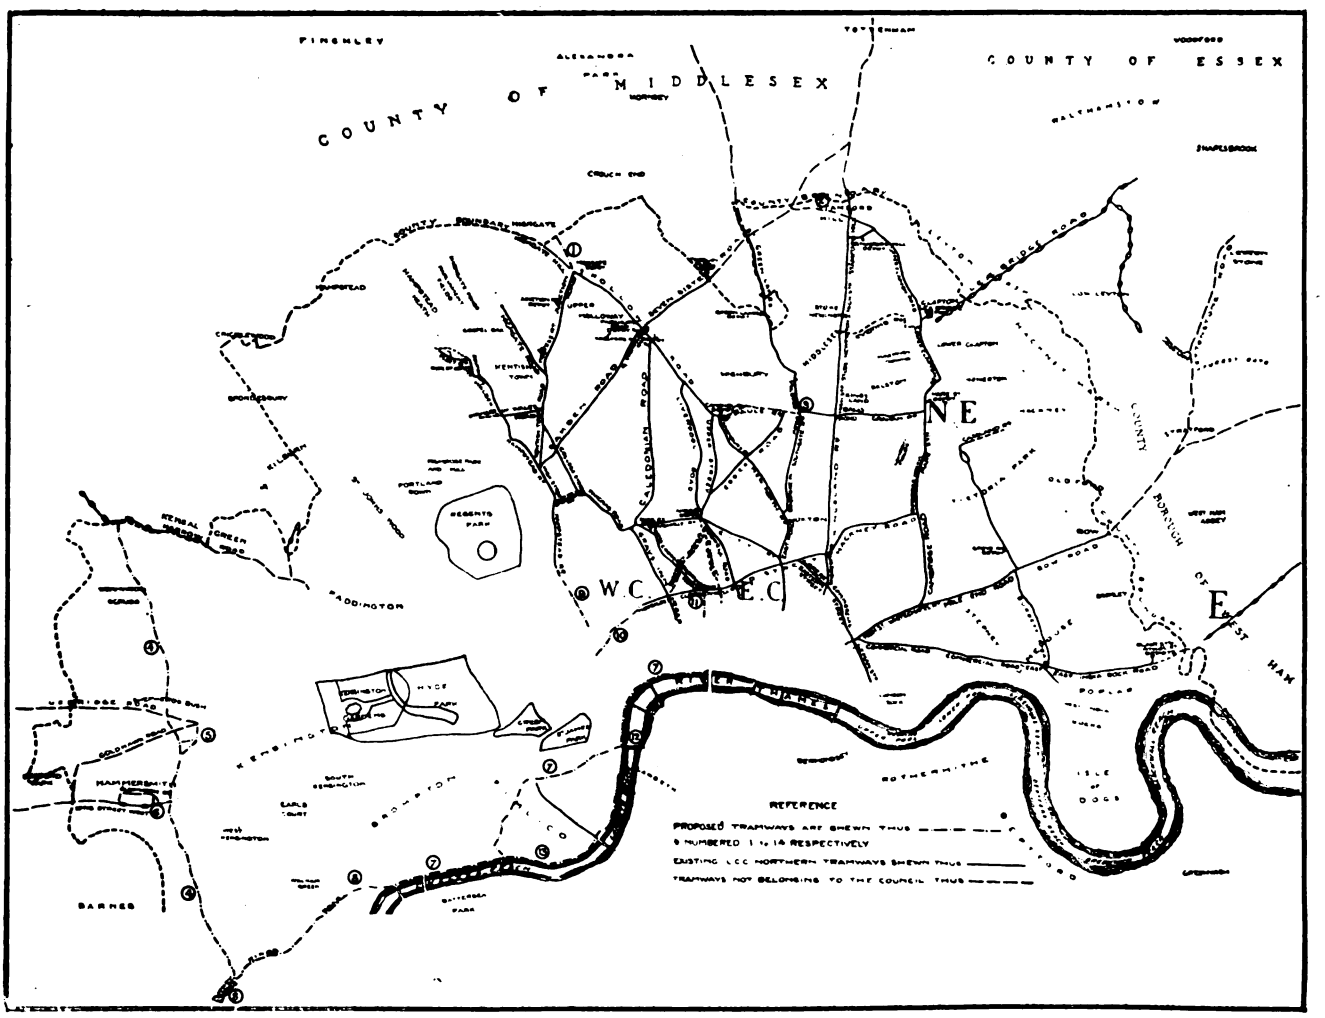

Diagram of Tramways North of the Thames.

consultation with the North Metropolitan Tramways Company, the Council's lessee. The Vestry of St. Pancras and the St. Giles District Board, the road authorities concerned, have both refused their consent, the Vestry stating that it cannot consider the proposal to extend the tramways along Tottenham Court-road until the southern end of Hampstead-road, which is very narrow, shall have been widened. There are already at the point indicated two lines of tramways coming up close to the Euston-road, and we think that, instead of the extension of these tramways as proposed causing congestion of traffic, it will rather tend to relieve it, owing to the fact that the stopping place for cars, instead of being, as now, close to the junction of the Hampstead and Euston roads, could be in Tottenham Court-road, where the carriageway is considerably wider. We think that there is little doubt that the new line, if constructed along Tottenham Court-road to near its junction with Oxford-street, where, owing to the removal of Bozier's-court, the carriageway is very wide, and quite suitable for a tramways terminus to be placed there, would prove a great boon to the public; and, by adding to the receipts of the Council's lessee, be remunerative to the Council. As may be seen from the foregoing remarks, we consider the construction of these proposed tramways to be very desirable in the public interest. The cost of the construction of this line for horse traction is estimated at £10,200, and

(*xi.*) *Farringdon-road* (tramways terminus), along that road to the *City Boundary*; length, 2 furlongs 4 chains.—This was suggested by the engineer, but his proposal was that the line should extend to a point near Ludgate-circus. The City Corporation was not prepared to assent to the tramways being laid within the City area; and our proposal is, therefore, that the line shall stop short at the City boundary. The Vestry of Clerkenwell is not unfavourable to the extension of the tramways, but is of opinion that, owing to the road being used as a costermongers' market on the one side, and to the unloading and loading of goods at warehouses on the other, it will be somewhat difficult to work tramway traffic along the road. We think, however, that, notwithstanding, the experiment might be tried. The road is sufficiently wide for a double line of tramways, and the estimated cost of construction is £4,500.

(*xii.*) *Victoria-embankment*, *vid* Westminster Bridge, to the London County Council tramway terminus in *Westminster Bridge-road*; length, 3 furlongs.—This suggestion was made by the engineer. The Vestry of Lambeth, the only road authority concerned, approves the principle of the proposal, and has expressed itself as strongly in favour of the extension of tramways over the bridges. The Council is itself the road authority for Westminster Bridge and the Embankment, and has on two or three occasions endeavoured, without success, to obtain

Digitized by Google

powers to construct tramways over the bridge; but we think that a further endeavour should be made to obtain the powers, as we are convinced that the extension of the tramways across the bridge would be of great benefit to a very large percentage of the users of the Council's tramways. No street widenings would be necessary, and the estimated cost of the construction of the tramways for electrical traction is £11,250, and for horse traction £5,600. We submit in this case alternative estimates, as we are informed that it is doubtful where there is sufficient space under the carriageway of Westminster Bridge to permit of the laying of the electrical conduit system.

(*xiii.*) *Chelsea Bridge* (north end), *vid* Grosvenor-road, to a point near *Lambeth Bridge*; length 1 mile 4 furlongs 8 chains.—This was suggested by the Vestries of Battersea and St. George (Hanover-square), and the other road authority concerned, the Vestry of St. Margaret and St. John (Westminster), does not disapprove of the proposal. This line would not at first be in connection with the London County Council tramways, although there is little doubt that it would eventually be so connected; and we think that it should be constructed for electrical traction. As this suggestion meets with the approval of the road authorities concerned, and the tramways manager is of opinion that the line would pay, we think that it should be adopted. The estimated cost of construction of the line for electrical traction is £50,000, and no street widenings would be necessary.

PROPOSED NEW TRAMWAYS—SOUTH OF THE THAMES.

(*xiv.*) *York-road, Wandsworth* (South London Company's lines), *vid* the new street 50ft. wide, in course of formation between York-road and Red Lion-street, along Red Lion-street, across High-street, along South-street, Garratt-lane, and Defoe-road to *High-street, Tooting* (London County Council lines); length, 2 miles 7 furlongs 8 chains.—The original proposal of the Wandsworth District Board was that the tramways, the whole of which will be in its district, should start from High-street, Wandsworth (South London Company's lines) and be taken as far as the London County Council lines in High-street, Tooting; but the District Board has since urged that the widening of Red Lion-street should be included among those in connection with the tramways proposals, so that the new tramways may extend from York-road along the route indicated above. The new street above referred to is being formed at the joint cost of the Council and the District Board, and it seems to us reasonable that the proposed widening, estimated to cost about £37,750, of Red Lion-street, so as to make it practically a continuation of the new street, should be carried out on the same terms. We believe that the District Board would be willing to contribute one-third of the cost of the widenings of Red Lion-street, South-street, Garratt-lane, and Defoe-road, provided that these thoroughfares be made 54ft. wide instead of 50ft. as first proposed, and on which assumption the original estimate of £188,500 was based. The adoption of the width required by the District Board will add £47,700 to the cost of the street widenings, being £25,900 for acquisition of property and £21,800 for paving, etc., works in the extra width of 4ft. from High-street, Wandsworth, to High-street, Tooting. The cost of the street widenings, including that of Red Lion-street, in connection with the whole proposal is estimated to amount to £273,950. We understand that the Improvements Committee has agreed to the extra width, and proposes to recommend to the Council that one-third of the cost of the street widenings shall be charged to the account of the improvements, one-third be contributed by the Wandsworth District Board, and the remaining third charged to the tramways account. We have already expressed our opinion with regard to the Red Lion-street widening, and although we are prepared to agree to one-third—namely, a sum not exceeding £63,000, of the cost of the other widenings to 50ft., according to the original estimate of £188,500—being charged to the tramways account, we are not prepared to go further than that, and we have so informed the Improvements Committee. From estimates which have been submitted to us it would appear that the prospective profits of the line would at first only be sufficient to pay interest and sinking fund on about £25,000 for street widenings and £90,000 for construction of the tramways, and, even if the charge to the tramways account for street widenings were only, as we propose, £63,000, nearly half of the charges for interest and sinking fund would have to be met from profits on other parts of the Council's tramways undertakings. There is little doubt that the proposed tramways, which are approved by the District Board and by the tramways manager, will be of great advantage to the district through which they will pass, and it is very probable that they will be valuable in connection with the housing of the working classes, besides becoming ultimately a safe and remunerative investment to the Council as a tramways proprietor. The estimated cost of the construction of these tramways for electrical traction is £90,000.

(*xv.*) *St. John's-hill*, near Clapham Junction Station (South London Company's lines) *via* Strath-terrace, Bolingbroke-grove and Bellevue road to the *Surrey Tavern*, at the junction of that road and *Trinity-road*; length, 1 mile 3 furlongs 1 chain.—The suggestion made by the Vestry of Battersea was that the proposed line should extend to, and join with, the London County Council lines at High-street, Tooting. This suggestion if adopted would, however, have involved extensive street widenings in Wandworth, to the cost of which the District Board did not see its way to promise to contribute; and we have therefore decided to recommend the construction of the tramways only as far as the Surrey Tavern, and for this purpose street widenings, estimated to cost £20,000, will have to be carried out. The consent of the Vestry of Battersea and of the Wandsworth District Board will be required to the construction of the tramways along the portions of the route within their respective districts, and we are informed that the Improvements Committee is prepared to recommend that, subject to these consents being given, and to the Vestry of Battersea agreeing to pay one-fourth of the cost of the street widenings in the parish, the Council shall undertake the street widenings, one-fourth of the cost being charged to the account of the improvements and the remaining half to the tramways account. With this arrangement we are satisfied, as we are of opinion that the proposed line will be sufficiently appreciated by the public to make it a remunerative investment for the Council as a tramways enterprise, even on these terms. The cost of the construction of the tramways for electrical traction is estimated at £47,500.

(*xvi.*) *Battersea Park-road* (South London Company's lines), *vid* Albert-road, to the foot of *Albert Bridge*; length, 4 furlongs 8·8 chains.—This is a suggestion of the Vestry of Battersea, and is supported by the tramways manager. He is of opinion that it would be of advantage to the Council to have powers to make the extension to Albert Bridge when it shall have acquired the company's lines, for the purchase of which, under the forty-third

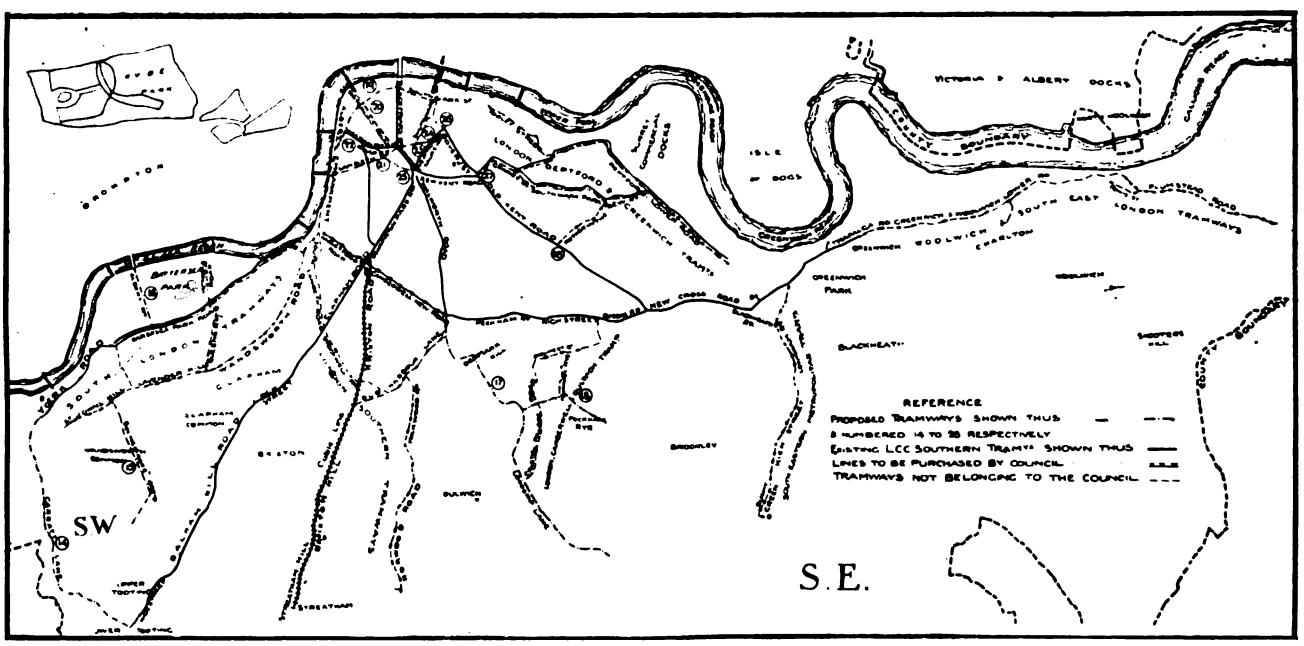

Diagram of Tramways South of the Thames.

Digitized by Google

section of the Tramways Act, 1870, the Council has decided to serve notice. The estimated cost of the construction of the lines for electrical traction is £18,500.

(*xvii.*) *Camberwell-green* (London County Council lines), *vid* Denmark-hill, Champion-park, Grove-vale, Lordship-lane, and London-road to *Devonshire-road*, near Forest Hill railway station; length, 3 miles 4 furlongs 6 chains.—This was suggested by the Vestry of Camberwell, one of the road authorities concerned; the others being the Vestry of Lambeth, which approves the proposal, and the Lewisham District Board, which has refused its consent. The manager is of opinion that this may be regarded as a trunk line, which would give to residents in Lordship-lane and Forest Hill direct means, which they do not now possess, of tramway communication with London; and, moreover, extensions could hereafter be made from this line into districts now totally without, but in great need of, tramway facilities. Some extensive street widenings would have to be effected before the tramways could be laid, and the cost of these widenings is estimated at £155,450. Of this amount the Improvements Committee proposes that the road authorities concerned should contribute one-third, that one-third should be paid out of the funds applicable to the improvement, and that the remaining third should be charged to the tramways account. The committee is prepared to recommend the Council to carry out the street widenings on this basis, with which proposal we agree. The estimated cost of the construction of the line for electrical traction is £107,000.

(*xviii.*) *Goose Green*, *vid* East Dulwich-road and Peckham Rye, to the junction of *Hall-road* and *Stuart-road*, *Peckham*; length, 1 mile 4 chains. The Vestry of Camberwell submitted a suggestion for the construction of tramways from Goose Green, to start from the proposed new line *xvii.*, to Inverton-road, Honor Oak, and the manager approved of this. We found, however, that the construction of a double line of tramways beyond Stuart-road would involve a considerable outlay for street widenings; and, after consultation with the manager, we have decided to recommend that the line shall go only as far as Stuart-road, up to which point no widening would be necessary. We are informed that there is every prospect of the line proving remunerative in conjunction with the line of which it would be an extension, and that it would be of benefit in affording facilities of access to the parts served by the Council's other tramways in the district of Camberwell, and also to London. The estimated cost of the construction of the line for electrical traction is about £31,500.

(*xix.*) *Southwark-street*, at Hop Exchange Corner (South London Company's lines), *vid* Southwark-street, Stamford-street, and York-road, and across Westminster Bridge-road, thence (single line) to *Lambeth Palace-road* (same company's lines), and returning *vid* Stangate over a proposed connection (*xvii.*) between the London County Council's lines and the company's lines near *Westminster Bridge*; length, 1 mile 2 furlongs 7·7 chains.—This was proposed by the St. Saviour's District Board, and is approved by the Vestry of Lambeth. We are advised that this line, if constructed, would afford additional travelling facilities most urgently required, and would be keenly appreciated by the public, and as a necessary consequence would prove remunerative to the Council. The carriageway in some parts of Stamford-street is not wide enough to admit of the statutory width of 9ft. 6in. being left between the outer rails of the tramways and the kerb, and, that being so, it will be necessary, in order to avoid having to effect street widenings which would be very costly, before the line can be constructed to obtain the consent of two-thirds of the owners and occupiers of property abutting upon the street at these points. We anticipate, however that there will be little difficulty in obtaining the necessary consents, as a space of about 8ft. would be left beyond the outer rail, and this would probably be sufficient to allow of a large-sized van standing at the side of the carriageway. The estimated cost of the construction of the line for electrical traction is £45,000.

(*xx.*) *Waterloo-road* (London County Council tramways terminus), along that road to a point opposite the *York Hotel*; length, 1 furlong 7·1 chains.—This is a very desirable extension of the lines in Waterloo-road, recently purchased by the Council from the South London Tramways Company. There is little doubt that the removal of the tramways terminus to a point nearer to Waterloo Bridge will be a decided advantage to the traffic, and will probably cause an increase in the number of passengers using the lines. The Vestry of Lambeth, the road authority concerned, approves of this extension. The cost of the construction of this piece of tramway for electrical traction is estimated at £6,500.

Proposed Junction Lines between London County Council Tramways and other Tramways.

(*xxi. to xxviii.*) The tramways manager has suggested that it is desirable that the Council should obtain powers for the construction of certain short junctions which will give facilities for interchange of traffic between the London County Council tramways and other tramways likely to be acquired by the Council within a short period. We think that the Council should endeavour to obtain powers to construct these junctions, particulars of which are given below, but we may point out that the powers, if obtained, need not be exercised until the tramways belonging to the companies concerned shall have come into the Council's possession:

(*xxi.*) From Westminster Bridge-road along St. George's-road to Lambeth-road—length, 1 furlong 4·2 chains; estimated cost, £5,500.

(*xxii.*) From Westminster Bridge-road (terminus) along Albert-embankment to Stangate (terminus)—length, 4·5 chains; estimated cost, £1,700.

(*xxiii.*) From Newington-causeway along Dantzic-street to Southwark Bridge-road—length, 3·9 chains; estimated cost, £1,500.

(*xxiv.*) From Newington-causeway along Borough-road to Borough-road at junction with Southwark Bridge-road—length, 1 furlong 2·9 chains; estimated cost, £4,900.

(*xxv.*) From Newington-butts along St. George's-road to St. George's-road—length, 1 furlong 3·3 chains; estimated cost, £5,000.

(*xxvi.*) From St. George's Church along Marshalsea-road to Southwark Bridge-road—length, 1 furlong 8·3 chains; estimated cost, £7,000.

(*xxvii.*) Great Dover-street to Bermondsey New-road—length, 4·4 chains; estimated cost, £1,700.

(*xxviii.*) Old Kent-road to St. James's-road—length, 3 chains; estimated cost, £1,200.

We recommend (*a*) that the standing orders of the Council relative to applications to Parliament for powers be suspended, in order that the Council may consider the following recommendation; (*b*) that the Council do make application, in the next session of Parliament, for powers for the construction of the undermentioned new tramways:

NORTH OF THE THAMES.

Archway Tavern (tramways terminus) to the county boundary in Archway-road.

Seven Sisters-road (existing lines), *via* Amhurst-park, to Upper Clapton-road (existing lines).

Mildmay-park (existing lines), westward, to Balls Pond-road (existing lines).

Harlesden (near the county boundary), *via* Scrubbs-lane, Wood-lane, Shepherd's Bush-road, Brook-green-road, and Fulham Palace-road, to Putney Bridge.

Uxbridge-road (near the railway station), *via* Richmond-road, Netherwood-road, and Westwick-gardens, to Shepherd's Bush-road.

Brook-green-road, at its intersection with Hammersmith-broadway, *via* that thoroughfare to Glenthorne-road (London United Tramways).

Victoria-embankment (Blackfriars end), *via* Victoria-embankment, Victoria-street, Buckingham Palace-road, Commercial-road, Bridge-road, and Chelsea-embankment, to the northern end of Battersea Bridge.

Battersea Bridge, *via* World's End-passage, Chelsea-embankment, New King's-road, King's-road, and Putney Bridge-approach, to and over Putney Bridge.

Hampstead-road (tramways terminus), across Euston-road and along Tottenham Court-road, to a point near Oxford-street.

Theobald's-road (tramways terminus), *via* Vernon-place, Bloomsbury-square, Hart-street, across Oxford-street, and along Shaftesbury-avenue, to Cambridge-circus.

Farringdon-road (present line), along that thoroughfare, to the City boundary.

Victoria-embankment, over Westminster Bridge, to Westminster Bridge-road (London County Council's tramways terminus).

Chelsea Bridge (north end), *via* Grosvenor-road, to a point near Lambeth Bridge.

SOUTH OF THE THAMES.

York-road, Wandsworth (South London Company's lines), *via* the new street in course of formation between York-road and Red Lion-street, along Red Lion-street, across High-street, along South-street, Garratt-lane, and Defoe-road, to High-street, Tooting (London County Council's lines).

St. John's-hill (South London Company's lines), *via* Strath-terrace, Bolingbroke-grove, and Bellevue-road, to the Surrey Tavern, at the junction of that road and Trinity-road.

Battersea Park-road (South London Company's lines), along Albert-road to the foot of Albert Bridge.

Camberweli-green (London County Council's lines), *via* Denmark-hill, Champion-park, Grove-vale, Lordship-lane, and London-road, to Devonshire-road, Forest Hill.

Goose Green, *via* East Dulwich-road and Peckham Rye, to the junction of Hall-road and Stuart-road, Peckham.

Southwark-street (South London Company's lines) at Hop Exchange Corner, *via* Southwark-street, Stamford-street, York-road, and across Westminster Bridge-road, thence (single line) to Lambeth Palace-road (same company's lines), and returning *via* Stangate over a proposed connection (No. 22), between London County Council's lines and the company's lines near Westminster Bridge-road.

Digitized by Google

Waterloo-road (London County Council's tramway terminus), along that road, to a point opposite York Hotel.

JUNCTION LINES.

Westminster Bridge-road (London County Council's lines), *via* St. George's-road, to Lambeth-road (South London Company's lines).

Westminster Bridge-road (London County Council's tramways terminus) to terminus at Stangate (South London Company's lines).

Newington-causeway (London County Council's lines), *via* Dantzic-street, to Southwark Bridge-road (South London Company's lines).

Newington-causeway (London County Council's lines) to Borough-road (South London Company's lines), at junction with Southwark Bridge-road.

Newington-butts (London County Council's lines) to St. George's-road (South London Company's lines).

St. George's Church (London County Council's lines), *via* Marshalsea-road, to Southwark Bridge-road (South London Company's lines).

Great Dover-street (London County Council's lines) to Bermondsey New-road (London, Deptford, and Greenwich Company's lines).

Old Kent-road (London County Council's lines) to St. James's-road (London, Deptford, and Greenwich Company's lines).

COMPANIES' MEETINGS AND REPORTS.

CITY AND SOUTH LONDON RAILWAY.

The thirty-second ordinary general meeting was held on Tuesday last at Winchester House, E.C., Mr. C. G. Mott presiding.

The **Chairman** expressed his disappointment at meeting the shareholders again with a reduced dividend, and believed that it would only prove temporary, it having been caused by exceptional circumstances which would not occur again. The report and accounts, containing the financial results, number of passengers, etc. (which appeared in last week's issue) were then presented. The cause of the lift accident which happened at London Bridge was, he stated, due to the breakage of one of the large steel shafts owing to the existence of a small flaw in it. The safety appliances attached to the lifts should have prevented such an accident as occurred to the cage, but the men employed by the contractors had been experimenting with the lifts and had taken off the safety balance. The accident had arisen from a combination of circumstances which was not likely to occur again. It had been arranged that the steel shafts in the lifts should now be 8in. in diameter, although this additional precaution really seemed to be unnecessary. The line had been worked for nearly 10 years without any previous accident to the lifts. Their platforms were connected with those of the Central London Railway by a subway, and another to connect them with the London Bridge Station of the Brighton Railway Company was being constructed. The extension to Islington was progressing favourably. He then referred to the capital and revenue accounts, and afterwards stated that the traffic was showing a satisfactory increase. For the first time the average receipt per passenger had exceeded 2d., the actual figures being 2·02d. When their line was first opened the uniform fare was 2d., but this had had to be altered owing to the omnibus competition for short distances. The Central London Company had also started with a uniform fare of 2d., but he feared that they would find it necessary later on to introduce modifications in their charge. The dividend recommended and agreed upon was 1¼ per cent. per annum for the half-year.

The motion for the adoption of the report was seconded by **Mr. C. S. Grenfell**, and carried.

EDISON AND SWAN ELECTRIC LIGHT.

The seventeenth ordinary general meeting of this Company was held on Tuesday at Cannon-street Hotel, E.C., Mr. J. Staats Forbes presiding.

The **Chairman** spoke of the large amount of stock which had accumulated owing to the establishment of branches in such a large number of towns. The articles in stock increased very largely from year to year, growing in proportion to the amount of the turnover. There was no occasion for alarm in this, but the Board had thought it necessary to make a very serious alteration in the stocktaking, and to revise the method of taking stock. They therefore came to the conclusion that they should close the year for the stocktaking by the month of June, which would give them something like absolute knowledge as to the nature of the stock. This had turned out to be a longer job than they had anticipated, but as far as it had gone the directors had every reason to believe that the stock, as stated in the account, was well within the actual saleable value of it from day to day. The profit and loss account showed that the stock was put down at £201,648 as an asset of the Company. This would not occur again, as they would have the stocktaking well up to the mark in 12 months' time. The report stated the amount available for distribution, after paying interest which had accrued. They had already paid something in the nature of a provisional dividend for the first half-year, and they proposed to pay at the same rate for the second half, making up a dividend of 6 per cent. for the year, carrying forward the balance of £6,199. Having ascertained since the accounts were made up that the stock carried into the balance-sheet was £6,000 at least more valuable than it was credited at, it would be seen that the balance might have been over £12,000 instead of £6,000. But the auditors, although they knew the stock was there, as the trade vouchers had not come in, would not give any credit for this, though there was no doubt that the money was there. The business of the Company had largely increased. For the corresponding period last year it was £241,400, while this year the turnover had been £285,500 The stock on May 31, 1900, amounted to £201,648, while the corresponding figure was £160,000. The item for depreciation on plant, etc., amounted to £13,936. The balance brought into the year was £10,599. The business had increased from £241,000 to £285,000, the stock had increased from £160,000 to £201,000, and the interest accruing from investments and other sources had increased by about £1,100. Against that there was the fact that the stock in hand at July 1, 1899, was £160,000; the wages, purchases, etc., amounted to £272,112; the salaries, directors' remuneration, etc., were £12,076. The depreciation on plant was £13,936, as against £9,000, and the balance of the profit and loss account was £43,388, as against £44,792. If they added the £6,000 which represented the value of the stock at its right amount, they would see that the balance was really £49,388, and it ought to be so but for the objection of the auditors. They had had to spend a good deal of money this year, and for that purpose they had raised fresh capital. This had come into charge, bringing the extra amount for interest up to £1,994. It cost them less to pay this interest than to pay the bankers for loans, and they had a considerable surplus to go on with. There was a rather heavy sum standing against sundry debtors and debit balances—£143,959, as against £90,000 in the preceding term. The Company gave long credit, and could not collect their money for some time, therefore the amount was brought in as approximate income for the month.

Mr. J. W. Swan, F.R.S., seconded the adoption of the report, which was carried unanimously.

On the motion of the **Chairman**, a dividend was declared at the rate of 6 per cent. per annum for the second half-year, making a dividend for the year of 6 per cent. per annum. The Chairman then said that he had reason to believe a combination existed amongst "B" shareholders and other dissatisfied shareholders in the Company, and he had taken upon himself the responsibility of issuing a circular sounding a note of warning, and to which the shareholders had responded in large numbers, so that there were no adverse proxies. He also took the opportunity of suggesting to the shareholders not to be in too great a hurry to part with their shares at a large discount. The directors knew when executors realised an estate, or when a shareholder sold his shares. The Board knew where they went to and upon what terms, and, therefore, they had thought it their duty to say that there was no reason for shareholders to part with their shares at less than their par value.

The meeting closed with a vote of thanks.

NATIONAL TELEPHONE.

The twenty-sixth ordinary general meeting of this Company was held last week at Cannon-street Hotel, E.C., Mr. J. Staats Forbes presiding.

In moving the adoption of the report and accounts (which appeared in our issue for July 20) the **Chairman** said that the net income had increased by £88,000, and the working expenses by £77,000, while the net result for the half-year was £227,262. The working expenses had gone up from 60·22 to 64·02 per cent., but that included the £25,000 of exceptional expenditure as the result of the snowstorm. The amount brought forward was about £2,000 less; the debenture and other interest had increased by £14,913, because in the interval the directors had issued debentures, and the interest on them had been paid up to date; and the preference and ordinary dividend was larger by £5,000, a portion of the ordinary shares sanctioned by the shareholders having been issued. The sum transferred to the reserve fund was £5,000 less than in the June half of 1899, and the amount carried forward was about £6,000 less. The directors proposed to pay the dividends upon the first, second, and third preference shares, and a dividend of 6 per cent. per annum, less income tax, on the ordinary shares; and they would carry £55,000 to the reserve fund.

The motion was seconded by the **Right Hon. Lord Harris, G.C.S.I.**, and adopted.

NOTTING HILL ELECTRIC LIGHTING.

An extraordinary general meeting of this Company was held at Winchester House on Wednesday last, when the following resolutions were adopted: "That the capital of the Company be increased to £200,000 by the creation of 10,000 new shares of £10 each, such new shares to rank as ordinary shares"; "That 2,200 of the new shares be issued forthwith at a premium of £2 per share, 1,100 to be offered *pro rata* to the holders of the founders' shares, and the remaining 1,100 *pro rata* to the holders of the ordinary and ordinary preference shares"; and "That the remainder of the new shares shall be issued at such times, and at such price, and under such conditions as the directors shall from time to time think fit, but so that the proportion thereof to be offered to the holders of the Company's founders' shares shall be the same as the proportion now offered under the last preceding resolution."

Digitized by Google

ANGLO-AMERICAN TELEGRAPH.

The half-yearly meeting was held on July 31 at Winchester House.

Mr. F. A. Bevan, who presided, stated that the ordinary receipts for the past half-year had been remarkably similar to those for the corresponding period of 1899, the difference in favour of the half-year under review having been £983. He observed that when the new German Azores cable was laid there would be no fewer than 13 cables across the Atlantic. Last year they earned over £19,000 from the repairing ship "Nina," but this year the amount had been reduced by £17,975. They had been laying a new cable between France and England; for many years they had a cable running from Salcombe to Brest, but it became worn, so the directors made a new line from Cuckmere to Havre. The new German Azores cable line was heavily subsidised by the German Government. This was to be opened on Sept. 1, and would then take a large portion of the outward traffic from Germany and America. With reference to the old subject of the French law-suit, he had been requested by their solicitor to ask the shareholders not to press this question on the present occasion. Matters were proceeding, but he could not prophesy what the result would be.

CROMPTON AND CO.

The ordinary general meeting of this Company was held on Monday last at Cannon-street Hotel, E.C., Mr. John Trotter presiding.

The **Chairman** gave a *résumé* of the report (which appeared in our last week's issue), and recommended the payment of a dividend at the rate of 9 per cent. per annum for the half-year, free of income tax, making with the interim dividend paid in January last 7½ per cent. for the year, and to carry the balance, £3,729, forward.

The report was adopted.

BIRMINGHAM AND ASTON TRAMWAYS.

Colonel E. J. L. Twynham presided at the meeting of the Birmingham and Aston Tramways Company, Limited, on the 27th ult., and drew attention to the increased cost of fuel.

Replying to an enquiry, **Mr. C. E. Mathews**, as solicitor to the Company, explained the position as to the possible handing over of the undertaking to the public authority. At present, he said, the Aston Council had a Bill under which they had powers to buy the line, and the Company might expect to hear from that body at any time. The notice to acquire would have to be a double one, for the Aston people could not buy one part of the line without buying the other.

The **Chairman**: At all events, we shall meet next year.

Messrs. C. Osborn and Lewis Richards, the retiring directors, were re-elected.

DUBLIN UNITED TRAMWAYS.

At the half-yearly meeting held on July 31, the **Chairman** (Mr. Wm. M. Murphy) declared that they had not yet arrived at the most economical basis for the production of electrical current, owing to the delay in the delivery of multiphase generating plant. They had to keep Ballsbridge station open for the present, but when they shut it down and supplied all the current from Ringsend that would represent the saving of £2,400 in a half-year. A dividend of 7 per cent. per annum was declared on the ordinary shares, an increase of 2 per cent. over last year. Nearly 18 million passengers were carried during last year, the number in 1891 being 8¼ million.

At a subsequent special meeting the Company was authorised to increase its borrowing powers by £300,000, to be issued as second debentures.

RAND CENTRAL ELECTRIC WORKS.

The annual general meeting was held on July 31 at Winchester House.

Sir C. Rivers Wilson, who presided, observed that, with reference to what passed at the meeting last year as to reserve fund, the directors had fulfilled their obligations by setting aside the small sum of £83, being 10 per cent. of the profit. Small progress was made as contrasted with that of the two previous years. In 1897 they worked at a loss of £16,000. In 1898 the loss was £5,472, and last year, working under favourable circumstances for three quarters of the year only, they came out with a small profit of about £840.

The report (already published in our last issue) was adopted, and it was resolved that, conditionally on Messrs. Siemens and Halske paying the Company in London within seven days £21,872. 8s. 1d., the proposed agreement referred to in the report be approved, and the directors authorised to carry the same into effect.

BRITISH ELECTRIC TRANSFORMER.

The report for the year ended 30th ult., to be submitted to the meeting to day, shows that, after paying all expenses and providing for repairs and depreciation, there remains a net profit of £6,184, which, with the amount brought forward from last year, makes a total available balance of £6,442. The Board proposes the payment of a dividend at the rate of 10 per cent. per annum on the subscribed capital, and a bonus of 2½ per cent. for the half-year, £2,120; to reserve fund, £2,500; to carry forward, £1,802.

LIVERPOOL OVERHEAD RAILWAY.

Abstract of the report of the directors, to be presented at the twenty-fourth ordinary half-yearly general meeting of the shareholders, to be held at the Law Association Rooms, 14, Cook-street, Liverpool, on Aug. 14:

In presenting the half-yearly statement of capital and revenue accounts to June 30, 1900, the directors have to report that the gross revenue receipts amount to £38,124. 1s. 2d., and the working expenses to £25,113. 3s. 9d. The number of passengers carried during the half-year ending June 30, 1900, is as follows: first-class, 635,449; second-class, including tramways, 2 477.025; workmen, special return tickets, 1,575,388—total, 4,687,862. There has been considerable delay in completing the Waterloo and Crosby tramways owing to the difficulty experienced by the local authorities in obtaining delivery of material. The line is now opened as far as Waterloo, and it is expected it will be completed to Crosby in about two months. The traffic on the portion opened has been satisfactory. The Bill in Parliament, promoted by the Company for the purpose of extending the main line to the Seaforth Station of the Lancashire and Yorkshire Railway, has passed both Houses of Parliament, and will, in due course, receive the Royal assent. The capital authorised at the last half-yearly meeting was offered to the shareholders on June 25 last in 5,000 ordinary £10 shares at £8 per share, and applications were received for considerably more than the amount required. The directors recommend the declaration of dividends at the following rates (less income tax), payable on and after Aug. 16 next: 5 per cent. per annum on preference shares, £3,000; 3 per cent. per annum on ordinary shares, £6,750; leaving a balance of £4,452. 12s. to be carried forward to next half-year.

CENTRAL LONDON RAILWAY.

The report of the directors for the half-year ended June 30 last states that the expenditure for the half-year amounted to £185,712, the total to June 30, 1900, being £3,353,596. The directors hoped to be able to open the railway for traffic in the early part of July, but their expectations were not fully realised, some modifications in the plant being found necessary during the experimental working, as explained in the engineer's report. The approval of the Board of Trade having been given, the railway was opened for traffic on Monday, July 30. In anticipation of the opening, H.R.H. the Prince of Wales, at the request of the directors, kindly inaugurated the undertaking by accompanying them, and other gentlemen connected with the company, in the first train that carried passengers over the whole length of the line. His Royal Highness was much interested, and cordially wished success to the new enterprise. As a commencement a week-day service of trains will be run from about 5 a.m. to 12 p.m., at intervals of five minutes, but more frequent trains will be provided, especially during the busiest hours of the day, as soon as practicable. A reduced service will be run on Sundays. Provision has also been made for the conveyance of workmen, in accordance with the company's Acts of Parliament.—*Financial News.*

WATERLOO AND CITY RAILWAY.

The report for the half-year ended June 30, to be submitted on the 9th inst., shows a total capital outlay of £589,073. A further expenditure of £25,000 is provided for by the capital powers of the Company. The gross receipts, less Government duty, amounted to £14,133. From this amount the London and South-Western Company retained £5 398 in respect of working expenses, leaving £8 735 payable by them, in order to provide, under agreement, for a dividend at the rate of 3 per cent. per annum, payable 11th inst., on the Company's ordinary and borrowed capital. The number of passengers carried during the past six months, exclusive of season-ticket holders, was 1,868,737, an increase of 152,912. The season-ticket holders on June 30 last numbered 911, as against 747.

Colchester.—The Town Council have entered into a contract with the War Office to light the barracks at 4½d. per unit for the first 50,000 units and 4d. per unit afterwards.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Halifax.—Tenders for incandescent lamps are required by the Corporation.

Lincoln.—The Town Council invite tenders for wattmeters and demand meters. Tenders by Sept. 14.

Sofia.—The District Treasurer invites tenders for the supply of telegraph material. Tenders by Aug. 6.

Hamburg.—Two 30-ton electric cranes are required. Enquiries may be made at the Town Hall. Tenders by Sept. 10.

Warrington.—Tenders are required by the Corporation for installation of mains and fittings at town hall and market.

Barcelona.—The Public Works Department, Madrid, invite tenders for a system of electric tramways in Barcelona. Tenders by Aug. 18.

Accrington.—The Corporation invite tenders for the wiring of their electricity works, Argyle-street, for electric lighting. Tenders by 10th inst.

Belfast.—The Electricity Committee invite tenders for the supply and erection of an auxiliary feed-water heater with pipe connections. Tenders by Aug. 15.

Stockport.—The Tramways Committee invite tenders for 20 double-deck tramcars, complete with electric equipment for overhead traction. Tenders by Aug. 31.

Bradford.—The Guardians invite tenders for the installation of electric lighting at their union workhouse. Tenders by Aug. 13. Details in our advertisement columns.

St. Petersburg.—The Posts and Telegraphs Department invite tenders for the working of the telephone systems in St. Petersburg, Moscow, Warsaw, Odessa, and Riga for 18 years from Nov. 1, 1901.

Salford.—The Corporation invite tenders for the supply, delivery, and erection of lighting cables, tramway feeders, and street lighting. Tenders by Aug. 13. Details in our advertisement columns.

Barnes.—The Urban District Council invite tenders for the supply and erection of pipework, condensers, etc., and overhead travelling crane. Tenders by Aug. 14. Details in our advertisement columns.

Paris.—The Association des Industriels de France contre les Accidents du Travail offer a prize of £40 for the best insulating gloves for the use of those employed in electric works. Particulars must be supplied by Dec. 31.

Newcastle-on-Tyne.—The Corporation invite tenders for the laying down in Newcastle of about five miles of double-line tramway, the rails and fastenings and the poles being supplied by the Corporation. Tenders by Aug. 22.

Edinburgh.—The Lord Provost, Magistrates, and Council are prepared to receive tenders for coal-conveying machinery for Dewar-place station, contract No. 54. Tenders by 13th inst. Details in our advertisement columns.

Leeds.—Tenders are invited for the lighting of St. George's Church, Leeds, with electric light. Particulars can be obtained by sending names to Mr. Henry Walker, architect, 8, Upper Fountaine-street, Leeds, before 8th inst.

Glasgow.—The Corporation invite tenders for the work in connection with lifting off roofs and other alterations to Maryhill tramway depôt. The whole of the work, which is principally joiners' work, will be let to one contractor. Tenders by Aug. 10.

Portsmouth.—The Corporation invite tenders for the supply, delivery, and erection of the whole of the plant and apparatus necessary to completely equip for electric traction their proposed power station at Vivash-road, Fratton-grove, Portsmouth. Tenders by Sept. 4. Details in our advertisement columns.

Torquay.—The Corporation invite tenders for two water-tube boilers, with superheaters, two inductor alternators and Willans engines, pipework, surface condensers, etc., extension to high-tension switchboard, wattmeters, etc., and transformers. Tenders by Aug. 6. Full details in our advertisement columns.

Grimsby.—The Corporation invite tenders to specification for the supply and delivery, in connection with the electric lighting of the borough, for additional steam dynamos: Section 1, engine; Section 2, dynamo; and extension of switchboard for dynamo No. 7, and traction work. Tenders by 18th inst. Details in our advertisement columns.

Aberdeen.—The Town Council invite alternative tenders for the supply of 650 tons steel girder straight-track tramway rails, weight about 100lb. per lineal yard; 150 tons steel girder curve-track rails, weight about 104lb. per lineal yard, in standard lengths of 60ft. or 45ft., as may be decided; also for 60 tons fishplates, weight about 75lb. per pair. Tenders by 24th inst. Details in our advertisement columns.

Grays.—The Urban District Council invite tenders for the supply, delivery, and erection of the following work in connection with the electric lighting of the district: (Section A) two Lancashire boilers and pipework; (B) two 100 kw. steam dynamos, with boosters and balancer; (C) fuel economiser; (D) switchboard; (E) battery; (F) travelling crane; (G) mains and street lamp fittings. Tenders by Aug. 9.

Hanley.—The Electric Lighting Committee invite tenders for the supply, delivery, and erection complete of two Lancashire boilers and fittings, including steam receiver; water-tank, girders, and pumps; fuel economiser, with engine or motor; smoke chimney, exhaust fan, with engine, etc.; feed-water heater; forced-draught fittings, firebars, or other appliances to boiler furnaces; and coal conveyor and bunkers. Tenders by 25th inst.

London, S.E.—The Directors of the South London Electric Supply Corporation, Limited, invite tenders for the supply and erection at their works at Bengeworth-road, Loughborough Junction, S.E., of a complete condensing plant for dealing with 28,000lb. of steam per hour, comprising surface condenser, steam-driven air and circulating pumps, cooling tower, and pipe connections. Tenders by 14th inst. Details in our advertisement columns.

London, W.—The Central Electric Supply Company invite tenders for the supply, delivery, and erection of (Specification 2A) dry-back marine boilers, 11ft. 6in. diameter and 14ft. long, gangways, feed and drain pipes, etc., complete, as required for each of three blocks of boilers. Each or all of the blocks can be tendered for, each block containing six boilers. Tenders are also to be submitted for mechanical stokers, with the shafting and gearing for driving them. Alternative tenders are invited for (Specification 2B) water-tube boilers as an alternative to the dry-back marine boilers, including the mountings, feed and drain pipes, etc. Copies of the specifications, with forms of tender, drawings, and general conditions, can be obtained from the General Manager, 19, Carnaby-street, Golden-square, W., on payment of £3. 3s., to be returned on receipt of a bona fide tender. Specifications and drawings can be seen at the office of Prof. Kennedy, 17, Victoria-street, S.W. Tenders, on the prescribed form, endorsed on the outside "Electric Plant—Tender to No. — Specification," must be sent to Mr. F. J. Walker, general manager, before 10 a.m. on Aug. 20.

London, E.C.—Tenders are invited by the Pacific Cable Committee on behalf of her Majesty's Government and the Governments of Canada, New South Wales, Victoria, New Zealand, and Queensland for the manufacture and laying in the Pacific Ocean of 3,272 nautical miles of telegraph cables between Vancouver and Fanning Island, Fanning Island and Fiji, Fiji and Norfolk Island, Norfolk Island and New Zealand, Norfolk Island and Queensland. It is proposed to divide the whole undertaking under three distinct contracts, for any one or more of which contractors may tender. Each of these contracts will include a clause under which the contractor guarantees the good electrical condition and working order of the cables for 30 consecutive days after the completion of the laying. A fourth contract is also proposed for surveying and sounding the whole route before the cables are laid. Forms of contract, specification, and tender may be obtained of Messrs. Clark, Forde, and Taylor, 4, Great Winchester-street, E.C., at whose offices charts showing the proposed route of the cable and the positions where soundings are to be taken may be inspected. The last day for the reception of tenders is Aug. 14. They must be enclosed in sealed covers, marked "Tender for Pacific Cable," must be addressed to Messrs. Clark, Forde, and Taylor, 4, Great Winchester-street, E.C., and must be delivered by 12 noon on that day.

RESULTS OF TENDERS.

Croydon.—Tenders have been accepted for the reconstructed tramways, motorcar equipments on the overhead principle, at £176,540.

Hampstead.—The Lighting Committee recommend that the tender of W. T. Glover and Co. be accepted for the supply of electric cables for the next 12 months.

Larne.—The Urban District Council have accepted the tender of the Larne Electric Light Works for the public lighting of town and boundaries for the ensuing three years from Aug. 1, at £535.

Hull.—The Corporation have accepted the tender of the Walsall Electrical Company, Liverpool, at £210, for the electric lighting installation and fittings for the Springhead pumping station, near Hull.

Newcastle.—The following tenders have been accepted: British Insulated Wire Company, trolley wires, £6,118. 15s. 7d.; S. Easten, 277, Westgate-road, Newcastle, for erection of the power station at the Manors, £32,544.

Hackney.—The Vestry have accepted a modified tender from J. Greenwood, Arthur-street, London Bridge, at £31,589. 8s. 6d., for the erection and construction of buildings, foundations, and chimney shaft for the Hackney electricity works.

London County Council.—The tender of Messrs. Pink and Moon to execute for £170 the alterations necessary to adapt a cowhouse at Farmfield as an engine-house, in connection with the electric light installation, has been accepted.

Hull.—The Electric Lighting Committee have accepted the tender of T. Parker, Limited, Wolverhampton, at £5,985, for the supply and erection of five high-tension continuous-current rotary transformers, with switch gear and accessories.

Beckenham.—The Urban District Council have received the following tenders for the erection of six brick transformer stations, 11ft. by 11ft. in size internally: F. W. Green, 62, Beckenham-road, Beckenham, £868; Foster Bros., St. Mary's-road, South Norwood, £737 (accepted).

Chelmsford.—The Town Council have accepted the tender of the Chelmsford Electric Lighting Company for lighting the public lamps in the borough, for a period of five years, at the following prices: for arc lamps £25. 5s. each per annum, and for incandescent lamps £3. 3s. per annum.

Bootle.—The Town Council have accepted the tender of Callender's Cable and Construction Company, Limited, London,

Digitized by Google

to supply and erect the arc lamps, cables, etc., required for the electric lighting of Derby, Rimrose, and Knowsley roads for the sum of £6,855. 1s. 5d., together with the further sum of £80 per annum for the maintenance of the cables for 10 years.

Hammersmith.—The following tenders are recommended for acceptance: Callender's Cable and Construction Company, for low-tension distributor cables and boxes (estimated total), £4 062; W. T. Glover and Co., for high-tension feeder cables (estimated total), £1,151; Watson, Gow, and Co., for 200 tons of 2in. cast-iron pipes at £7. 5s. per ton, £1,450, and 4 tons of specials at £9 per ton, £36.

Cardiff.—The Corporation have received the following tenders for the manufacture of about 1,000 tons of steel tramway rails; also for fishplates, sole-plates, tie-bars, bolts and nuts, points and crossings, drain rails, copper rail bonds, etc.: Dick, Kerr, and Co., rails and fishplates £8,522, tie-bars £565; Ibbotson Bros., fish-bolts and nuts, £170; Bayliss, Jones, and Bayliss, sole-plates, £508; Askham Bros., points and crossings £267, two crossings £88, drain rails £378; Felten and Guilleaume, copper bonds, £618. These tenders have been recommended by the committee for acceptance.

Dublin.—The Electric Lighting Committee, acting on the advice of Mr. Robert Hammond, M.I.C.E., the consulting engineer, have recommended the Council to accept the following tenders for the plant for the new electricity works at Pigeon House: Polyphase generators, with compound engines—General Electric Company, Limited, London (D. Stewart and Co., Glasgow, engines; Oerlikon, Switzerland, generators), £33,061. Boiler-house plant—Holdsworth and Sons, Lancashire boilers, £6,653; Holdsworth and Sons, economisers, £1,060; Babcock and Wilcox, Limited, water-tube boilers, £5,278.

BUSINESS NOTES.

TRACTION.

Central London Railway.—This line was opened to the public on Monday, and 84,500 passengers were carried on that day, and 90,000 on Tuesday.

Paisley.—Mr. Murphy's Tramway Bill has now been dropped. No further attempt will be made to revive the Bill during the present session of Parliament.

Aberdeen.—An enquiry has been commenced into the alleged refusal of tramway conductors to stop at the stations when there were people waiting to get on the cars.

Norwich.—Lieutenant-Colonel H. A. Yorke, R.E., made an official inspection of the Norwich tramway system on behalf of the Board of Trade on Thursday last week. The whole system was in full working yesterday.

Barrow.—The negotiations for the running of the present steam trams by electricity are making progress. It is expected that a complete system of electric trams will be running within 12 months in the town, also to the docks and Furness Abbey.

Oldham.—At Wednesday's meeting of the Town Council a resolution was carried empowering the town clerk to apply for leave to borrow £280,000 for the construction and equipment of the tramway scheme and the necessary works and buildings.

Chalk Farm.—The County Council on Monday informed the Hampstead Vestry that it has decided for the present to abandon the proposed tramway from Chalk Farm to Edgware-road, as the Vestry has not agreed to contribute to the cost of the necessary public improvements.

Manchester.—The Council have authorised the Tramways Committee to obtain tenders for the erection of temporary car-sheds and stables, and for the supply of the requisite horses, cars, and other equipment for working the tramways by horse traction until such time as the electrical system is complete.

Blackpool.—It is expected that everything will be in readiness for the work of laying the new electric tramway round Marton being rapidly proceeded with during the coming autumn and winter. The Tramway Committee have accepted tenders for the supply of rails and the complete electrical equipment for the whole route.

Sunderland.—Some of the new cars for the Sunderland electric tramway service, which is to be opened shortly, have arrived in the town. A trial was made on the 31th ult. of one of the new electric cars on the route from Christ Church-to Roker section. The journey was made in nine minutes, and the trial went off without hitch.

Adelaide.—We learn from the *New South Wales Railway Budget* that the South Australian Government will oppose any measure which proposes to hand over the city and suburban tramways to any private ownership for an indefinite time, or to any corporation or group of corporations, to the detriment of the rest. The Premier has asked the Railway Commissioners to report to him on the probable cost of acquiring the existing lines and converting them into electric trams.

Southwark.—At the last meeting of the St. Olave's Board of Works a letter was read from the London County Council, expressing their intention to seek powers to form an electric tramway along the new southern approach to the Tower Bridge when parliamentary powers had been obtained. They, however, proposed to proceed with the laying of the rails in anticipation of parliamentary sanction being obtained in order to prevent disturbance of the roadway when complete. The proposal was approved subject to wood paving being laid instead of stone.

Sheffield.—The electric car service on the Abbeydale-road section was commenced on the 28th ult. For some time the route has been electrically equipped, but the sanction of the Board of Trade has not been obtained. The Board of Trade having recently intimated that they are unable at present to send an inspector to examine the electric appliances, and if the Corporation deem it expedient they can run the electric cars at their own risk, the Tramways Committee decided to adopt this course.

Derby.—The proposed new tramways will be 13 miles 1 furlong 2 21 chains. The routes have been fixed, and the Tramways Committee have decided to recommend the Council to take powers for the compulsory acquisition of property near the electric lighting station, containing an area of about 6,030 square yards, as a site upon which to erect buildings for the generation of electricity. The Council has been recommended to approve the scheme, and to sanction the insertion of clauses in the next Bill in Parliament for alteration of the existing system, for the proposed extensions, for the scheduling of land proposed to be acquired for street widening and for generating station.

Southampton.—At a recent meeting of the Borough Council, the Sheriff expressed his regret to the inhabitants of Shirley for the bad tramway accommodation they were receiving. The committee had had new wheels put to the trailers, so that the latter might be utilised on the route, but even with them it was impossible for the committee to cope with the traffic. When they saw there was a jump from 50,000 to 120,000 passengers per week, and there were only 12 cars, they would not be surprised at the committee's inability to give an efficient service under the present circumstances. They had urged on the contractors, but he was afraid they would not have the additional cars for some time.

Stoke-on-Trent.—At a recent meeting of the Town Council the town clerk was instructed to draw the attention of the Potteries Electric Traction Company to the decision of the Court of Appeal in the case of the borough of Hyde *v.* the Oldham, Ashton, and Hyde Electric Tramway, Limited, the British Electric Traction Pioneer Company, Limited, and others, and to ask them whether, in the face of that decision, they still refused to sign the agreement as to the cables prepared by the town clerk and previously submitted by him. Proceedings were ordered to be taken against the Electric Traction Company, Limited, for the nuisance caused by the emission of black smoke from the chimney of their works in Bewstead-street.

Maidstone.—At a meeting of the Town Council on Monday, the General Purposes Committee recommended the desirability of application by the Town Council for a provisional order for the establishment of an electric tramway through convenient parts of the borough. The acquisition of an order would prevent adventuring companies making efforts to obtain one. Trams would give the working classes better facilities for reaching their homes. It was also urged that one of the great drawbacks to the electric light was that they would not have sufficient work in the daytime. Tramways would meet that difficulty. The report was adopted, formal resolutions in favour of making the application, and instructing the Electric Lighting Committee to have plans prepared, being carried.

Folkestone.—At the last meeting of the Council the minutes of the proceedings of the Tramways Sub Committee were read. From the same it appeared that the borough surveyor had been instructed to prepare the necessary plans for deposit in connection with parliamentary proceedings for powers to construct tramways for Folkestone. The sub-committee were also of opinion that it was not desirable that tramways should be constructed along the whole length of the Lower Sandgate road, but recommended that the Corporation scheme should include a line from the harbour, past the north side of the Pavilion Hotel, along Marine-terrace, Marine-parade, and the Lower Sandgate-road as far as the entrance to the Victoria Pier. The town clerk reported that the parliamentary agents recommended Messrs. Kincaid and Co. as an eminent firm of tramway engineers, and it was resolved to apply to them for their terms for submitting an estimate of the cost of the proposed tramways. This was done, and Messrs. Kincaid, in reply, undertook to furnish the Council with a report giving them an estimate of the cost of the construction and equipment of the tramway suitable to the requirements of the town for 50 guineas, together with travelling and hotel expenses. It was reported that an expert of Messrs. Kincaid's had visited the town for the purpose of making a report, and had been met and shown round by the mayor and the town clerk. After a lengthy discussion the matter was deferred until Lord Radnor's agents had been approached, and the Council had received the report and plan from the expert.

Birmingham.—From the report of the Public Works Committee, presented at the quarterly and special meeting of the City Council on July 31, we gather that after experimenting with sample poles and brackets the committee came to the conclusion that the wires should be suspended from centre poles along the Horse Fair and Bristol-street as far as Bromsgrove-street, and that in Suffolk-street and between Bromsgrove-street and the city boundary the wires should be suspended from poles with side arms. The wire is to be 5ft. 6in. from the kerbstone, except in the length between Wellington-road and Priory-road, and in the case of a few trees between Wellington-road and Belgrave-road, where it is to be 8ft. 3in. from the kerbstone. The type of car approved by the committee for use on the line is a four-wheeled double-decked car of the pattern known as the Liverpool pattern. It will accommodate about 46 passengers, and will be comfortably fitted up and well lighted. The bonding of the rails with copper bonds will be

Digitized by Google

carried out by the company, and the electric feeders will be laid by the committee under the supervision of Mr. Vaudrey, the city electrical engineer, to an approved specification and at the cost of the company. A formal agreement, embodying the terms already reported to the Council, has been entered into with the company, and the town clerk has been instructed to join the company, on behalf of the Corporation, in any application that may be necessary for the sanction of the Board of Trade to work the tramways on the overhead system. Negotiations are pending with reference to the application of the Birmingham and Midland Tramway Company for permission to equip, on the overhead electric system, the tramways leased to them, between Lionel-street and the city boundary in Dudley-road.

Bournemouth.—The General Purposes Committee's report, adopted without discussion at the last meeting of the Council, reads as follows: "The report by Messrs. Lacey, Clirehugh, and Sillar (the consulting engineers) and Mr. F. W. Lacey (borough engineer) on the tramway scheme was read. (*a*) Mr. Lawson proposed, Mr. Hawker seconded, to recommend that the joint report of the electrical engineers and borough engineer be adopted and carried out; and it was so unanimously resolved. (*b*) Mr. Lawson proposed, Mr. Newlyn seconded, to recommend that a committee be appointed to carry out the scheme as set out in the report, including the electric lighting mentioned in it, to consist of the Mayor, Aldermen Davis and Mattocks, and Councillors Abbott, Beckett, Gunning, Hawker, Hoare, Lawson, Mate, and Stockley; and it was so unanimously resolved. (*c*) Mr. Davis proposed, Mr. Hawker seconded, to recommend that application be made to the Urban District Council of Winton for their consent and assistance to the Corporation constructing a tramway in continuation of the Corporation tramway No. 11, along the Wimborne-road, to a point to be agreed on in the urban district; and it was so resolved. (*d*) It was resolved to recommend that the necessary steps be taken to apply for a provisional order under the Tramways Act, 1870, to supplement the order for the present session by authorising the construction of the additional tramways recommended in the above report, and the extension of tramway No. 11 to Winton. Land in Southcote-road.—Mr. Lawson reported negotiations with the owners of land in Southcote-road adjoining the Corporation depôt there. Recommended that the Tramway Committee be authorised to enter into a provisional contract for the purchase of the property in the Southcote-road known as the Cumberland Estate, through Messrs. Bicker and Pettitt, in connection with the tramway scheme."

Croydon.—At the last meeting of the County Borough Council the Tramways Committee reported: "The committee recommend that paragraph 2 of their report of May 31 last be rescinded, and that the tender of the British Thomson-Houston Company for the supply of 35 car bodies of the type made by Messrs. G. and F. Milnes and Co., of Birkenhead, be accepted in lieu of that made by the Brush Electrical Engineering Company. With reference to paragraph 6 of the report of this committee of Jan. 18 last, the committee recommend that a double line of tramway be laid from the Swan and Sugarloaf, Brighton road, to the borough boundary at Purley, and from the Thornton Heath Pond to the borough boundary at Norbury. The committee have had a conference with the Roads Committee with regard to the wood paving of the roads, but are unable without further information to make any definite recommendation to the Council with regard to this work. They propose again to meet the Roads Committee on Monday, and hope at the meeting of the Council to lay a definite proposition before them. Subject to the committee being able to do this, and to the acceptance of their recommendation by the Council, they recommend that the following tenders be accepted: British Thomson-Houston Company, Limited, motorcar equipments, feeders, test wires, road work, and overhead construction; J. Smith and Sons, Limited, additional car-sheds, Thornton Heath depôt; Mr. E J. Saunders, Brighton-road depôt buildings." Subsequently the Roads Committee met, and recommended no tender for the reconstruction of the track, but that it be done by the Tramways Committee in conjunction with the Roads Committee, these committees being empowered to advertise for and accept tenders for materials, and engage such labour as would be necessary. The amended estimates, therefore, were: reconstruction of track and paving, £102,000; overhead equipment contract, less a reduction (estimated) of £1,000 in connection with the use of the trolley poles for arc lighting, £20,045; feeders, test wires, and road work, £12,963; car bodies (35), £9,680; motorcar equipment, £13,052; excavation and guard wires, £1,400; car-sheds, £9,400; engineer's commission, £3,000; contingencies, £5,000—total, £176,540. The reports were agreed to.

LIGHTING AND GENERAL.

Metropolitan Electric Supply Co.—The transfer registers will be closed from 4th to 13th inst. inclusive.

Rand Central Electric Works.—Mr. H. Rogers has been appointed secretary vice Mr. H. Militz, resigned.

Shoreditch.—The Vestry have obtained from the London County Council a loan of £42,400 for electric lighting purposes.

Potteries Electric Traction Co.—The transfer books of the preference shares will be closed until the 15th inst. inclusive.

Castner Electrolytic Alkali Co., U.S.A.—Letters of allotment of the £200,000 £5 per cent. first mortgage debentures have been passed.

Guernsey.—The works of the Edmundson Corporation, Limited, at Amballes, were inaugurated last week by Sir T. G. Carey, bailiff.

Crewe.—At Wednesday's meeting of the Town Council it was decided to spend an additional £10,000 upon electric lighting.

London Gazette.—A receiving order has been made out *re* W. V. Scott, Shaftesbury-road, East Hammersmith, on creditors' petition.

British Electric Traction Co.—The transfer books and register of members of the preference shares will be closed until the 15th inst. inclusive.

Meyra Electric Co.—We have received from this Company a new price-list giving particulars of their dry batteries for electrical purposes.

Electric Automobile Syndicate, Limited.—A general meeting of members of this syndicate is announced for Oct. 3 to receive the liquidators' statement.

Thurlstone.—It has been arranged for a deputation to meet the Penistone Council and the Guardians on Aug. 9, to discuss the question of electric lighting.

Atlantic Cable.—The German Atlantic Telegraph Company will shortly lay the second section of the German-American cable from New York to the Azores.

Southgate.—The Council is taking steps to join with the other local authorities in approaching Parliament with a view to securing an order for the supply of electric light.

Battersea.—The foundation stone of the central electric generating station in Lombard-road will be laid on the 18th inst. by Mr. W. Mathews, J.P., chairman of the Vestry.

Cardiff.—It appears that negotiations are about to be reopened between the Public Works Committee and the National Telephone Company for the laying down of underground wires.

Twickenham.—The Council have given their formal consent to the application of the Department, dated Oct. 10, 1899, for permission to lay a system of underground pipes in the district.

Partnership.—We are informed that Messrs. F. E. and A. S. Elmore have entered into partnership as consulting electro-metallurgists, and have opened offices at 4, Bishopsgate-street Within, E.C.

Crystal Palace.—The effects of the recent accident were quickly alleviated by means of the plant kept in reserve within the building. This was brought up to 1,100 volts, and nearly three-quarters of a mile of cable were laid as temporary mains.

Leicester.—The total output of electric current from the central station for the half-year ending June 30 last was 489,055 Board of Trade units, as against 342,327 units in the corresponding period of last year, being an increase of 146 728 units, or 42 86 per cent.

Reno Inclined Elevator Syndicate.—The directors of this syndicate propose to hold a private view of their Reno inclined elevator at the Crystal Palace to day, this being the first time in which this patent electric stairway has been worked in the United Kingdom.

Lancaster.—The price for electric current is to be advanced as follows: for motor purposes, from 3d. to 3½d. per unit; for lighting purposes, 4½d. to 6d. per unit. It is stated that the electric lighting will be extended to North Ward as soon as there was a sufficient request from the applicants.

Accrington.—The Electric Lighting Committee propose to ask Messrs. Glover upon what terms they would be prepared to put in the house services from the mains to the meter previous to deciding whether they will employ Messrs. Glover to do the work instead of at once appointing a staff of wiremen.

W. T. Henley's Telegraph Works Co.—Interim dividends for the six months ended June 30, 1900, will be paid on Sept. 1, 1900, as follows: on the ordinary shares at the rate of 8 per cent. per annum, less income tax; on the preference shares at the rate of 4½ per cent. per annum, less income tax.

Patent Decision.—The Thomson-Houston Electric Company have obtained a decree, with costs, in the United States Circuit Court, South District, of New York, U.S.A., for an injunction against the Lorain Steel Company against the infringement of their claims 1, 2, 3, and 4 of the patent motor switch interlocks (Knight, Patent No. 428,169).

Bradford.—Mr. John Brigg, M.P., has given notice in the House of Commons to ask the Secretary to the Treasury, as representing the Postmaster-General, if he will explain why one part of the telephone district around Bradford is allowed to communicate by telephone with the post office at Bradford, while other parts of the same telephone district are not allowed the same privilege.

Appointments Vacant.—The Electric Lighting Committee of the Hull Corporation are prepared to take two electrical improvers into their electric light works for a period of two years, at a premium of £30.—The Tramways Department of the Glasgow Corporation require the services of a first-class mechanical engineer to take charge of the steam plant and general oversight of their power station.—Applications are invited for the post of senior demonstrator of electrical engineering at the South Western Polytechnic, Manresa road, Chelsea. Salary, £150 per annum.—Telegraph linesmen are required in Lagos. The engagement is for three years, with possible extension. Salary, £200 per annum Half-pay during voyage out. Free quarters or rent. Travelling expenses in colony. Second-class passages out and home, including rail third-class. After 12 months' continuous service six months' leave, with free passage and full salary. Applications will be received by the Crown Agents for the Colonies, Downing-street, London, S.W., on or before Aug. 13. Full particulars of these vacancies appear in our advertisement columns.—A switchboard, a fitter driver, and a jointer are required at Rochdale electricity works.

Digitized by Google

Walker.—Sanction has been received for the following loans: £8,288 for a refuse destructor; £18,418 for electric lighting, etc.; and £1,700 for electric free wiring. The Newcastle Electric Supply Company's Bill, as amended, has been read a second time in the House of Lords and passed the committee.

Cork.—At the last meeting of the Council the standing orders were suspended for the consideration of a recommendation to the effect that the public lighting of the city by electricity be extended by the erection of 85 additional arc lamps. The motion was discussed at great length, but was finally rejected.

Chester-le-Street.—The Chester-le Street Parish Lighting Company, Limited, intend to apply to the Board of Trade on or before Dec. 21 next for a provisional order authorising them to supply electricity for public and private purposes within the whole of the district of the Chester-le-Street Rural District Council.

Nelson.—Application is to be made for sanction to a loan of £2 500 for battery and switchboard for the electric lighting station. The question of the unsatisfactory state of the electric cables in Netherfield-road and Railway-street has been placed in the hands of Mr. Gibbings, the consulting engineer of the Town Council.

Egremont.—The Bill to confirm the Egremont electric lighting order of the District Council has received the Royal assent. The North British Electricity Supply Company, King-street, South Shields, intend to apply for a provisional order and confirming Bill to authorise them to supply electric energy within the urban district of Egremont.

Holiday Tours.—The Great Eastern Railway Company have issued several well-illustrated and handy booklets which they call annotated time-tables, and which give by the side of the usual figures a description of the places of interest passed by the train. Those we have seen refer to the Aldeburgh and Hunstanton express trains respectively.

Sunbury.—The Twickenham and Teddington Electric Supply Company, financed by the Edmundson's Electricity Corporation, who have just passed a Bill through both Houses for the supply of Twickenham, where they intend to erect their station, are now about to apply for powers to supply a district including Teddington, Sunbury, and Hampton.

Keswick.—The added portions of the Urban District Council—Great Crosthwaite and Chestnut Hill, Brow Top, etc.—were lighted for the first time on Monday. Each pillar is fitted with dual lamps, one only of which is lighted; but there is an automatic arrangement to switch the current on to the other in the case of damage to the filament of the one in use.

Swanage.—The Urban District Council have deferred giving their consent to the application of the Bournemouth and Poole Electricity Supply Company to a proposed provisional order, pending enquiries which are being made from other district councils which have adopted electric light to ascertain whether it would pay the Swanage Council to adopt the system.

Brighouse.—At last week's meeting of the Town Council a letter was read from the North British Electricity Supply Company, giving notice of their intention to apply for powers to supply electrical energy for public and private purposes within the borough of Brighouse, and the Gas and Electricity Committee were instructed to take the necessary steps when the Bill was deposited.

Newmarket.—The postal authorities having submitted a tracing showing the course of the proposed trunk telephone line between Bury St. Edmunds and Newmarket, the Council decided to refuse the sanction to the erection of poles and wires in the main thoroughfares of the town. They agreed to draw attention to the fact that already the telegraph wires are carried underground until they are outside the town.

Removal.—We are informed that the Edison and Swan Company, owing to the expansion of their business, have removed their supply department to large warehouses, 27, College hill (almost immediately opposite their head offices and showroom in Queen-street), where there are departments for the supply of accessories, electroliers, bell goods, glass, wires, and cables, etc., of which there are large and varied stocks.

Harrow.—A committee of the Council has under consideration the specification of the Harrow Electric Light Company for the wiring of the offices. They have agreed to recommend that instead of having a big centre 10 light fitting as described in the specification, that a three-light centre piece and five single pendants be fixed over the tables at a cost of £4. 5s. instead of £10, this meaning a saving of £3 in the wiring contract.

Brompton and Kensington Electricity Supply Co.—The directors have declared an interim dividend at the rate of 7 per cent. per annum on the preference shares and an interim dividend of 5 per cent. per annum on the ordinary shares for the half-year to June 30 last. The transfer books of the ordinary and preference shares respectively will accordingly be closed until 7th inst. for the preparation of dividend warrants payable 8th inst.

Aberdeen.—Mr. Bell has submitted plans showing how he proposes to lay out the ground at Dee Village for the purpose of the new electrical station, and they have been remitted to Mr. Smith (gas manager) and Mr. Bell for a report on the whole subject. Tenders will now be issued for additional plant, consisting of two 200 kw. sets and one 420 kw. set. The new plant has to be ready to meet the demands for electric lighting in the autumn and winter of 1901.

Metropolitan Asylums Board.—At the meeting of the Board on Saturday last, letters were read from the Local Government Board promising to issue an order authorising an additional expenditure of £1,280 on the electric light installation at the North-Western Hospital—the amount to be obtained by a loan which should be repaid in 10 years—but adding that they are advised that the amount of the electrical expert's charges in connection with the work was extraordinarily high.

Stourbridge.—The Urban District Council have adopted a report of their Destructor and Electric Powers Committee on the question of the utilisation of the provisional order obtained by the Council for the supply of electricity within the area of the urban district, advising that steps should be taken to lay down a plant sufficient to supply the present needs of the town. The committee also recommended that the application for a provisional order by the Midland Electric Corporation be opposed. The committee only proposes to supply a restricted area with electricity.

Tunbridge Wells.—The town clerk has received notice of an appeal by the National Telephone Company against the recent decision giving the Tunbridge Wells Corporation power to prevent the laying down of underground telephone wires. The Lighting Committee recommend the Council to at once proceed to erect an additional chimney, at an estimated cost of £3,500, and to obtain tenders for the execution of the work, which is to be carried out under the superintendence of Mr. Maxwell, the borough surveyor. A new flue and economiser, estimated to cost £1,000, which are rendered necessary by the erection of the new chimney, are also to be provided.

Fire.—On Friday night the lightning set fire to the Post Office telegraphs and telephones testing station and stores at Weedon. Within this testing station meet 172 main-line wires from Ireland, Scotland, and all parts of England, and pass through a delicate and expensive testing apparatus, which immediately and exactly locates a fault on any of the lines. The fire was soon extinguished, but many of the wires were fused and the testing apparatus was seriously damaged. The Post Office electricians at Weedon immediately set to work, and by joining the wires, without running them through the station, succeeded in restoring all communications by daybreak the next morning.

Stock Exchange.—The Stock Exchange Committee have ordered the British Aluminium Company's 20,000 7 per cent. cumulative preference shares of £10 each, fully paid, Nos. 1 to 20 000, to be quoted in the official list. Applications have been made to the committee to appoint a special settling day in and to grant a quotation to the Castner Electrolytic Alkali Company's (of the United States of America) £200,000 5 per cent. first mortgage sterling debentures of £100 each, and the County of London and Brush Provisional Electric Lighting Company's provisional certificates for £100,000 4½ per cent. debenture stock, and to appoint a special settling day in the Calcutta Electric Supply Corporation's further issue of 10,000 shares of £5 each. Application has also been made for Crompton and Co.'s further issue of 21,902 ordinary shares of £3 each, fully paid, Nos. 32,099 to 54,000, to be quoted in the official list.

Chichester.—The *Hampshire Telegraph* says: "The Chichester Town Council is now in a curious position with regard to the question of supplying electricity for lighting purposes. After one or two preliminary debates, and a report from a firm of electricians, it resolved more than two years ago to apply for a provisional order giving power to carry out electric lighting work to the exclusion of private companies. The order was obtained at an expense of nearly £300, but was for two years only. Since then the Council has considered a scheme proposed by the city surveyor, and approved, with some modifications, by Mr. Price, electrical expert, of Portsmouth, but at the last moment postponed the consideration of it, a further expense of 50 or 60 guineas being incurred. The order expired on July 1, and immediately the Council were apprised by the North British Electricity Supply Company of South Shields that they intend applying by memorial to the Board of Trade for a provisional order to authorise the company to supply electrical energy for public or private purposes within the city."

Dover.—We learn that 35 Dover Electric Light Company £5 shares were sold by auction recently by Messrs. Worsfold and Hayward. Ten sold for £7l. 5s., 20 for £135, and five for £33. 15s. The company has been in existence five years, and the amount above par realised in these shares is equal to 7½ per cent. on the investment for the whole period, without reckoning the 3 per cent. dividend received from the company last year. The Dover Electricity Supply Company have agreed to reduce the cost of lighting the Granville Gardens from £25 to £10, though the former amount is under the estimated cost, but the company desire that electric light should become popular. The National Telephone Company have made application for permission to lay underground telephone wires in various streets, etc., which will be sanctioned subject to their being laid under footways, to the proviso that if the municipality of Dover should afterwards obtain a license that the Telephone Company should agree to inter-communication over their wires, and that the company should pay a substantial sum for the concession.

Condensers.—We have received from Messrs. T. Ledward and Co., of 35, Queen Victoria-street, London, E.C., one of their latest catalogues, which gives a great deal of useful information relating to condensers, both of the ejector and evaporative types, manufactured under Ledward's patents. The advantages of condensing, as compared with non-condensing, engines are incidentally pointed out, while full directions are given for fixing the apparatus illustrated. Some excellent diagrams taken from engines working in conjunction with Ledward's patent ejector condensers are also given, together with numerous testimonials as to the efficiency of the apparatus supplied by the firm and a long list of electrical and other engineering works, etc., which have adopted the condensers.

Digitized by Google

A quantity of other useful information and tables relative to the expansion of steam, properties of saturated steam, strength of cast-iron pipes, diameters, areas, and circumferences of circles, etc., are included. The catalogue should be found exceedingly useful both by those wishing to instal condenser plants and those wishing merely to learn something about condensers.

Hammersmith.—The Electricity and Lighting Committee on Wednesday submitted a report with regard to the proposal to obtain a supply of water from the River Thames to the electricity station for condensing purposes, and the installation of a new system of condensing plant more applicable to the great advances anticipated in the capacity of the generating station in the future, the estimated cost of the works as approved by the Vestry on that date being as follows: excavation of road and laying pipes, £1,750; sewer, £2,200; penstocks, £150; cast-iron pipes, £1,800; sundry work to surface of road, £150; pumping station, £300—making £6,350; to which is added pumps, motors, and cables, £1,300; condensers and pipes, £1,250; contingencies, £1,100—bringing the total estimate to £10,000. The committee stated that they had approved plans prepared by the surveyor showing the various details included in the foregoing estimate of £6,350, and recommended that the plans be adopted, and that the surveyor be instructed to prepare specifications of the work, and that the matter be referred back to them to obtain tenders and report.

Parliament.—In the House of Lords during the past week the London, Walthamstow, and Epping Forest Railway (Abandonment) Bill was read a second time. The following Bills were read a third time and passed: Liverpool Corporation, Exeter Corporation, Christchurch and Bournemouth Tramways, Metropolitan District Railway, South Wales Electrical Power Distribution, and Plymouth, Stonehouse, and Devonport Tramways, West Ham Corporation, West Bromwich Corporation, South Lancashire Tramways, London County Tramways (No. 2), Newcastle-on-Tyne Electric Supply, Durham (County of) Electric Power Supply, Lancashire Electric Power. In the Commons the following Bills were read a third time: Rotherhithe and Ratcliff Tunnel, Ipswich Corporation Tramways, Great Grimsby Street Tramways, Roe's Patent, South Shields Corporation, Walsall Corporation, Rotherham Corporation, Whitechapel and Bow Railway. The Brompton and Piccadilly-circus Railway Bill was withdrawn. The Lords amendments to the following Bills were considered and agreed to: Aberdeen Corporation Tramways, Burnley Corporation.

Air-Compressors and Hoists.—Messrs. Reavell and Co., Limited, of Ranelagh Works, Ipswich, have sent us a nicely-executed and well-illustrated catalogue of the air-compressors and hoists manufactured by them under Reavell's patent. Amongst many others, an air-compressor of the "Quadruplex" single-acting type arranged for electrical driving is shown. The motor and the compressor are connected together by gear wheels, which run in an oil bath. This arrangement makes a combined plant, which can be moved about from place to place if the requirement of the work render this desirable All of the standard sizes quoted are adapted for electrical driving, and for the latter purpose the firm undertakes to supply motors when particulars as to the voltage available are given. The compressors are of the high-speed type, especially designed to work quietly at a fairly high speed, and to give a continuous supply of air, so as to reduce the size of the reservoirs which at present are used with pneumatic equipments. They are suited for supplying compressed air at 80lb. to 100lb. pressure for working all kinds of pneumatic tools in workshops, and the electrically-driven type is eminently adapted for colliery and quarry work, where compressed air is employed for rock drilling, etc. Full descriptions and dimensions, besides the prices of the different standard sizes, are given.

City of London.—At Thursday's meeting of the Court of Common Council a report was adopted on applications from the Postmaster-General to open up certain streets in the City, and erect stagings in support of wire cables. It was pointed out that the Postmaster-General wished to use, without the payment of any rent, the subways owned by the Corporation. According to the resolution passed on Thursday, the Corporation are reserving the right to charge such a rent as it might be entitled to. A similar application by the National Telephone Company in regard to the subways in front of the Mansion House was rejected. The following recommendations on the proposed erection of a generating station at Marsh Gate-lane, Bow, were agreed to: "(1) That the purchase money to be charged against the City undertaking for the portion of the site required for the erection of the City generating station be determined *pro rata* to the cost of the whole site; (2) that the Charing Cross and Strand Electricity Supply Corporation shall not acquire any interests in adjoining land without the previous consent of the Corporation being obtained, such consent, however, not to be unreasonably withheld; (3) that the Corporation agrees to allow the company the necessary running powers over the proposed line of railway shown on the plan submitted, subject to a nominal rental, and without prejuice in any way to the rights of the Corporation to use or alter such line of railway."

Morecambe.—Arrangements had been made by which the Electric Launch Power Syndicate was to obtain power for their launches from the Urban District Council's works at 3d. per unit, but this appears to have been only a temporary concession, as the Urban District Council recently attempted to increase this charge to 7d. per unit, which would be prohibitive. The directors have now succeeded in again getting this price reduced to the original 3d. The current is supplied to the generating station at the end of Calton-terrace at a pressure of 220 volts, and by means of a motor-dynamo the current is transformed to the voltage required by the boats. The cables are then conveyed by an iron main laid underneath the stage to an iron standard erected above the ordinary high-water mark at the foot of the landing-stage, where by means of cables attached to watertight boxes at the top of the standard the boats can be charged at their moorings. As a beginning two boats have been provided. The "Lady Ada," specially built for the company by the Vril Launch Company in the Isle of Wight, is 28ft. long, with a draught of 2ft. 6in., and carries 30 passengers; whilst the "Lady May," which was built on the Thames, is 40ft. long, with a draught of 2ft. 6in., and carries 45 passengers. Both are very handsome screw boats, capable of travelling 7½ knots, or about 10 miles, an hour, and a peculiarity is their great safety even in rough weather. The machinery, weighing about 2½ tons, is exactly in the middle of the boat, so that the danger of capsizing even when broadside on in a high sea is reduced to a minimum.

Bristol.—The Electrical Committee recently submitted a statement of the accounts of the electrical undertaking for the year ended March 25 last. The number of consumers on March 25, 1900, was 1,215, being an increase of 248 during the year. The number of lamps connected was 85,956 (of 8 c.p.), as compared with 68,536 at the corresponding period of the previous year. During the year a number of motors have been connected with the mains. The use of electricity for motive power in Bristol is in its infancy, and judging by its extensive use for similar purposes in other towns, the committee anticipate a much larger demand when its advantages are better known. The number of units sold was 1,812,511, being an increase of 449,725. An examination of the accounts will show that the financial results of the year have been satisfactory, considering that the effect of the reduction in the charges for private lighting made on Oct. 1, 1898, and for public lighting made on Jan. 1, 1899, has been felt throughout the year, whilst only a part of the previous financial year was affected. The gross receipts amounted to £31,717. 14s. 2d., and the gross expenditure to £17,962. 1s., leaving a gross profit of £13,755. 13s. 2s., from which has to be deducted interest on loans and bankers' overdraft, £6,019. 15s. 8d.; repayment of money borrowed, £7,590—£13,609. 15s. 8d.; leaving a balance of £145. 17s. 6d. The following statement exhibits the financial position of the undertaking at March 25, 1900: total capital expenditure, £252,588. 7s. 2d.; mortgage debt, £228,750; less paid off or set aside, £30,110—£198,620; balance at credit of reserve fund, £5,000; balance at credit of depreciation account, £2,024 17s. 7d. The accounts have been audited by Mr. Edwin John Richards, A.C.A., and Mr. Solomon Hare, F.C.A., city auditors, and their certificate is appended. A report from the city electrical engineer, statements as to the financial and commercial progress, and an historical note of the undertaking, were appended.

Gravesend.—In view of supplying the town of Gravesend with electric light and power, Mr. W. H. Trentham, consulting electrical engineer, has prepared a report for the chairman and members of the Electric Lighting Committee of Gravesend. As it is not easy to keep apart the two questions of light and power for tramway traction, Mr. Trentham proposes to combine them, but to keep the question of a refuse destructor apart. He gives figures concerning the electric lighting of 12 towns of a similar size as Gravesend, in which 10 show a profit, in one instance of nearly £2,500, while only two show a loss on the working. The following were the principal objections with which Mr. Trentham dealt with, one after the other, in a satisfactory manner: (1) that there is no demand for the electric light; (2) that electricity is very much dearer than gas; (3) that profits have only been made in much more populous towns than Gravesend; (4) that the light is not yet perfected, and that the time has not yet arrived for such an undertaking to be embarked upon; (5) that residents having already gone to the expense of having their premises fitted up with gas will not incur the, to some at all events, comparatively heavy cost of putting in wires and fittings for electricity. As soon as the electric supply is available the tramway company will require 280,000 units per annum, and if a charge of 1·63d., the rate paid at Wrexham, be made, the revenue under that head will be £1,925, but it is proposed to charge 1·75d., considering the present price of coal, which would bring this revenue to £2,041. It is proposed to erect a destructor to deal with 5,000 tons of refuse per annum, or about one ton per hour, at a cost of £3,500. The site proposed is near the gasworks. The lighting would only be done in the principal streets only at first by 800-c.p. arc lamps, 23ft high, and placed 65ft. apart. The following points were successfully proved: (1) that as electric lighting pays well in other towns of similar size, it should also pay in Gravesend; (2) that the addition of the tramway load would enable the undertaking to pay at an early date; (3) that if a destructor be established it should be in combination with the generating station.

Hornsey.—The Electrical Committee of the Urban Council at the last meeting recommended that Mr. Robert Hammond be appointed engineer to carry out the scheme for the supply of electrical energy for lighting and other purposes in the Hornsey district, subject to an agreement to be prepared by the Council's solicitor embodying Mr. Hammond's duties and remuneration as set out in the following particulars: Duties—to attend all necessary conferences with the Electricity Supply Committee in order to settle details of scheme; to draw specifications and prepare plans of plant, buildings, and works for public tender; to conduct all necessary correspondence with, or attend at, the Board of Trade to obtain "sanction of system"; to prepare necessary plans, data, etc., for the Local Government Board; to attend Local Government Board enquiry in connection with their granting sanction to loan; to report to the Electricity Supply Committee on the tenders received for the plant, buildings, etc.; to settle

Digitized by Google

technical details of contracts; to settle contract drawings and tabulate same; to inspect the plant in course of manufacture at makers' works; to inspect the progress of the work during execution on site; to prepare the maps of completed mains in accordance with the requirements of the Board of Trade; to keep the records of the accounts with contractors, measure up the work on site, and certify payments due to contractors as the work progresses; to undertake testing of plant on completion, and certify as to conformity of same with specification; to act as arbitrator in case of dispute under the contracts; to undertake all general engineering duties connected with the carrying out of the works, and to advise the Electricity Supply Committee throughout progress of works in all matters connected with the contracts and with the establishment of the undertaking. and to attend meetings of committee when necessary. Mr. Hammond's remuneration to be 5 per cent. on the cost of the executed work except buildings and any other work done by the Council's surveyor, payable as follows: 2½ per cent. on the amount of the contracts as they are from time to time given out, and the balance in the form of 2½ per cent. on the amount of certificates issued from time to time as the work proceeds. And in addition to the above fee of 5 per cent. an allowance to be made of such sums as the Council may on the recommendation of the Electricity Supply Committee from time to time consider reasonable, during the execution of the works to cover the services of clerk of works to be employed in superintending the carrying out of the work on the site thereof, and also an allowance for all reasonable travelling expenses incurred in the inspection of plant during construction. The report was adopted. The plans for the buildings are to be prepared by Mr. Lovegrove, the engineer to the Council.

Victoria Embankment.—On Tuesday the Highways Committee of the London County Council reported as follows: "We have, under the authority given to us by the Council on Feb. 15, 1898, invited tenders by public advertisement for the supply of the lamp standards which will be required in connection with the electric light installation for the Victoria embankment and Westminster Bridge; and the tenders received were opened at the meeting of the Council on July 10, and referred to us. It was stated in the advertisement that each person tendering was to submit his own design for the standards, or if he so desired he might submit alternative designs; and the specification contained an intimation, for the guidance of persons tendering, that the price considered adequate was about £30 per standard complete. The tenders sent in were as follows: A. Brown and Sons, Londonderry, £27 per lamp; Mackenzie Bros., Edinburgh, £28. 5s.; J. Allen and Son, Glasgow, £29. 10s.; W. Macfarlane and Co., Glasgow (two designs), £29. 10s. or £31; R. Carr and Co., London (two designs), £30; W. A. Baker and Co., Newport, Mon. (two designs), £32. 10s. or £35; W. Lucy and Co., Oxford, £34. 10s.; W. Singer and Co., Frome, £35; T. Brown and Co., Birmingham, £39. 10s. We have carefully examined the designs submitted, and have had the advice of the architect and the chief engineer with reference to them. Those submitted by Messrs. Macfarlane and Co. appeared to us to be the most satisfactory, and we asked them to submit a further design embodying what we considered to be the best points of each of those submitted with their tender. We have given instructions for all the designs, including the amended one sent in by Messrs. Macfarlane and Co., to be on view in the lobby of the Council chamber when this report is under consideration. Messrs. Macfarlane and Co. are willing to manufacture and supply the lamp standards which will be required, about 65 in number, at the price £30 each, making £1,950 in all, and to commence delivery within 100 working days from the date of order and to complete the delivery within 134 working days. The period allowed in the specification for the delivery of the standards was three months from date of order, and the time asked for by Messrs. Macfarlane and Co. is somewhat more, but we think that this may be conceded. It will be seen that other tenders were of less amounts than the price asked by Messrs. Macfarlane and Co.; but we would point out that in a matter of this kind, where the artistic character of the designs is a factor which must be considered, the small difference in price should not be allowed to stand in the way of the best design being adopted. Provision for the expenditure for, among other things, the lamp standards was made in the estimates, amounting in all to £25,000, approved by the Council on July 13, 1897, and Feb. 15, 1898, in respect of the electric light installation; and we recommend that the Council accept the tender of Messrs. W. Macfarlane and Co., for the supply of about 65 arc lamp standards, at the price of £30 each, required in connection with the electric light installation for the Victoria-embankment and Westminster Bridge, such standards to be completed in accordance with the design submitted to, and approved by, the Highways Committee on July 26, 1900."

LEGAL INTELLIGENCE.

TELEGRAPH LINES UNDER THE STREET.

Builders have an additional enemy to encounter. Telegraph lines under the street level have to be carefully guarded against. In the Edinburgh Small-Debt Court the first case of its kind in Scotland was heard recently. The Postmaster-General claimed £9. 8s. 1d. from Adam Loch, contractor, Shardwick place, Edinburgh, in respect of damage done to the telegraph line below a street in Leith, where defender was carrying on building operations. It was stated on behalf of the head of the Post Office that the telegraph line was melted by the heat from a tar-boiler which defender was using, and it was contended that under the Telegraph Act Mr. Loch was liable. Authorities from the English Courts were quoted in support of the contention.

Defender's plea was that as he did not know that the telegraph line was there, he should not be held liable. He had only carried out his operations in accordance with the recognised custom of the trade.

The Sheriff held that defender was liable, and accordingly gave decree for the amount sued.

ACTION DISCONTINUED.

The action between the Jandus Arc Lamp and Electric Company, Limited, and Mr. William James Davy has come to an abrupt ending by the action of the plaintiffs, who have notified that they wholly abandon their case.

THE POTTERIES TRAMWAY CONTRACT.

The case of Fell *v.* the British Electric Traction Company was further heard on Monday in the Queen's Bench Division of the High Court before Mr Justice Kennedy and a special jury. Mr. Lyttelton, Q.C., and Mr. Richards appeared for the plaintiff, and Mr. Pickford, Q.C., and Mr. H. Davies for the defendants. The case was to allow Mr. J. Fell, contractor, the plaintiff, to recover £5,872 alleged to be due to him under contract. This claim was denied by defendants. Some further evidence was heard on both sides, and the jury found a verdict for the defendants, and judgment was given accordingly for the defendants with costs.

PROVISIONAL PATENTS, 1900.

JULY 23.

13249. Improvements in and connected with the electrical transmission of images and in the recording of images. William Friese-Greene, 55, Chancery-lane, London.

13280. Improvements in arc lamps. Johann Friedrich Ackermann, 40, Chancery-lane, London. (Complete specification.)

JULY 24.

13293. Overhead railway signal by contact alarm. John Ephraim New, 29, Milton-villas, Clodeshall-road, Upper Saltley, Birmingham.

13356. Improvements in telephonic relays. William Phillips Thompson, 6, Lord-street, Liverpool. (Josiah Tice, William Grant Urmson, John William Parsons, and Henry Augustus Bell, United States.) (Complete specification.)

JULY 25.

13375. Improvements in or relating to electric ignition plugs Harry Frederick Atkins, 18, Hertford-street, Coventry.

13385. Improvements in the method of and means for medically applying electricity. Charles Thayer Driggs, Fife House, Kingston-on-Thames.

13401. An improved electrical converting transformer. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (La Société Anonyme pour la Transmission de la Force par L'electricité, France.)

13406. Improvements in or relating to insulating materials. Friedrich August Gottlieb Kirchberg, 111, Hatton-garden, London.

13415. Improvements in and in the manufacture of electric insulators. Carlos Alfonso López, 36, Chancery-lane, London. (Complete specification.)

JULY 26.

13447. An improved electric tramway system employing alternating currents, preferably polyphase. Claud Carew-Gibson, Hampden House, Phœnix-street, London.

13448. Electricity used in tanning. Axel Theodor Wedelin, 18, Eldan-street, London.

13472. Improvements in telegraphic transmitting, receiving, and translating arrangements. Alexander Muirhead, 323, High Holborn, London.

13478. Improvements in electric motor starting and regulating switches and cut-outs. Herbert Francis Hunt, 11, Burlington-chambers, New-street, Birmingham.

13479. Improvements in and relating to aerial conductors and like apparatus for transmitting and receiving electromagnetic impulses. James Tarbolton Armstrong and Axel Orling, 40, Vartry-road, South Tottenham, London.

13482. Improvements in current collectors for electric traction. Emile Bede, 4, South-street, Finsbury, London.

JULY 27.

13496. Improvements in electric switches. Walter Frederick Jones, Albert Works, Hammersmith, London.

13515. Improvements in or relating to overhead trolley wires or conductors for electric traction, overhead electric cables, or the like. Robert Hacking, 111, Hatton-garden, London.

Digitized by Google

13533. Improvements relating to electric motor vehicles. Edmond Draullette, 45, Southampton-buildings, Chancery-lane, London.

13538. Improvements in or connected with current arresters. James Grieve Lorrain, Norfolk House, Victoria-embankment, London. (Peter C. Burns, United States.) (Complete specification.)

13539. Improvements in or connected with current arresters and alarms. James Grieve Lorrain, Norfolk House, Victoria-embankment, London. (Peter C. Burns, United States.) (Complete specification.)

13540. Improvements in electric igniting arrangements for internal-combustion engines. Pierre Mauguin, 47, Lincoln's-inn-fields, London.

JULY 28.

13573. Improvements in apparatus for electrically lighting railway trains. Edwin Thorley Parker, Prince's-chambers, Wolverhampton.

13585. Improvements in electric ignition devices for internal-combustion motors. Pierre Mauguin, 47, Lincoln's-inn-fields, London.

13592. Improvements in or relating to electric light fittings. Henry Hill, 111, Hatton-garden, London.

13698. A new or improved current receiver or trolley for electric railways with overhead current conducting system. Georg Nast, 18, Buckingham-street, Strand, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on August 18.

1899.

13274. Manufacture of accumulators. Schanschieff.

15268. Electric lamps. British Thomson-Houston Company, Limited. (Rice.)

15911. Electromagnetic apparatus. Jones.

16382. Spindles and the driving of the same by electricity. Lorrain. (Sawyer and Robb.)

17257. Apparatus for generating electrical pressure. Adams.

17953. Means and appliances connected with air-tight electric arc lamps. Rathbone.

19129. Means to be employed in the electrolytic manufacture of chlorates. Imhoff, Raschen, and United Alkali Company, Limited.

21562. Separator for plates of secondary batteries. Leitner.

22338. Electrical switches. Evered and Co., Limited, and Evered.

1900.

5727. Electric heating and apparatus therefor. Trudeau.

6703. Magneto-electric machine for igniting purposes. Bergmann.

3866. Electric signalling apparatus. Newton. (Carleton.)

9373. Electric motors, batteries, and connections thereof for propelling automobiles and like vehicles. Hewitt, Lindstrom, and Hewitt.

10323. Telephone cables and apparatus for producing same. Cassirer.

10711. Electric signalling apparatus for railways and the like. De Filippi.

11190. Switches for high-tension electrical currents. Siemens Bros. and Co., Limited. (Siemens und Halske Aktiengesellschaft.)

NOTES.

Books Received.—We have received from Messrs. Longmans, Green, and Co. a copy of a book by Mr. Thomas Willans, entitled "The Life of Sir James N. Douglass, F.R.S.," formerly engineer-in-chief to the Trinity House.

Wireless Telegraphy.—We mentioned last week that experiments in wireless telegraphy were to be conducted between Ilfracombe and the Mumbles. The pole used is very tall, measuring 115ft. in height, and the apparatus is the ordinary Marconi coherer, the messages being taken on Morse printing instruments. The engineer in charge of the installation is, we learn, Mr. C. Harris, sectional engineer at Exeter Post Office.

French Automobiles.—We gather that there has been a split in the camp of the French automobilists, owing to one section of the French Automobile Club complaining that the other section did not do enough to encourage the use of automobiles in France. The dispute has resulted in the formation of a new club called the Moto Club of France, and we expect to hear soon that the employment of automobiles is going ahead at a high speed.

Japanese Railways.—We learn from the *Electrical World* of New York, that private advices from Japan state that the long projected railway from Nagoya to Seto will soon be an accomplished fact, and that it has been virtually decided that the motive power will be electricity. The capital of the enterprise, which has been furnished by the Japanese, has been increased from £25,000 to £40,000. Specifications are about to be prepared, and the electric equipment of the road will, it is estimated, mean an expenditure of £16,000.

The Sydenham Explosion.—The effects of the boiler explosion at the Crystal Palace Company's works do not appear to have been entirely got over yet. Thus during last week one side of Westow-hill and parts of Sydenham were plunged into darkness, and shopkeepers have had to resort to oil lamps, candles, and other primitive methods of illumination. It is not, we gather, expected that the electric light will be in working order for some little time. An inquest has been held on the bodies of the victims, another death having resulted from the explosion.

Feilden's Magazine.—The first birthday number of this magazine has just been issued. The number is a very good specimen of the whole of the numbers for the year which has just ended, and is very well illustrated and printed. It contains articles on "Railway Rolling Stock of High Capacity," the Simplon Tunnel, the Paris Exhibition, and the London Tramways and Light Railways Exhibition. There are also other articles and short notes, besides the usual review, called "Industrial Progress," which contains commercial notes gathered from all sources. The cover for this birthday number is unusually gay, but is at the same time very well executed.

A Right Decision.—The Brooklyn Rapid Transit Company are to be congratulated on the conviction of the three men who have lately done so much damage in attempting to depress the market value of the company's stock by spreading false reports. The charge brought against them was that of conspiring to depress the Brooklyn Rapid Transit stock, and one of the jury was offered a bribe to hold out and prevent an agreement as to guilt. The jury, however, found the prisoners guilty, and one was sentenced to six months' imprisonment and the other two to three months', the former having to pay also a fine of £100 and the latter two £50 each.

Electro-Embalming.—It is stated in the Portuguese Press that Dr. Variot, of Paris, has discovered a process for embalming bodies which he hopes will prove a great success. He not only embalms, but metalises the bodies by electroplating them. In this manner they can be preserved indefinitely and in such perfection that the most imperceptible wrinkles and lines are reproduced, and the embalmed body has the appearance of a metal statue. In order to electroplate a body it is given a bath in pure carbolic acid, and being strongly rubbed with nitrate of silver, the body is submerged in a galvanic bath, after which a slight layer of nitrite is applied to it.

Electric Cartridges.—We see it noted in *Commercial Intelligence* that a native of Italy has invented an electric cartridge, which he offers as a substitute for dynamite and smokeless powder in mines, rock blasting, and for heavy ordnance. The composition used in the cartridge is made up of carbonates of potash and chloride of ammonia, the proportion varying according to the use. The discharge is effected by an electric spark, which produces electrolytic effects upon the chemicals. The inventor claims that the cartridges, until subjected to the effect of electricity, are entirely inoffensive and perfectly safe; so that there will be no necessity for isolating the magazines where they are stored.

Colours in Artificial Light.—It is interesting to note that in matching colours the best substitute for daylight is the electric arc. In an article on the subject, the *Upholstery Trades' Review* states that after the arc light comes the magnesium flame, and under favourable atmospheric conditions the colourist, by examining his shades in the light of burning magnesium, may get their true daylight aspect. The aspect of colours under the electric arc light is, in nearly every case, identical with good daylight. There are, however, a few special cases where the dyed colours are extremely sensitive to any variation in the purity of light, and in these a slight difference is noticed between their daylight and electric light aspect.

A Large Electric Crane.—What is stated to be the largest electric crane in England has just been erected at the new armour-plate works of Messrs. Armstrong, Whitworth, and Co., at Openshaw. The crane, which is an overhead travelling machine, has been erected in the armour-plate casting department. It has during the last week or so been subjected to severe tests as to its lifting capacity, and during one test lifted a load of 135 tons. The span possessed by the crane is 100ft., and it is operated by means of four large electric motors, which can be easily switched on and off. On the whole, Messrs. Vaughan and Son, Limited, the makers of the apparatus, have every reason to be proud of so successful a piece of work.

The Cincinnati Strike.—We are pleased to find that the threatened strike of the employés of the Cincinnati Street Railway Company is not to take place. This is one of the instances recently where both employers and employés have agreed to consider in a fair and open way the questions raised. Owing to this, what threatened to be a serious disturbance of the traffic in Cincinnati has now been got over without any straining of the relations of the two parties interested. Amongst the reforms which have been agreed to, the company will reduce the hours of their motormen and conductors, and will allow employés in plain clothes to ride free on production of their badges. The company have also promised to arrange a system whereby the employés will be paid a regular dividend on an amount equal to their annual wages at the same rate as the shareholders receive on the shares they hold.

Institution of Junior Engineers.—The annual summer meeting is this year to be held at Newcastle-on-

Digitized by Google

Tyne from Monday next, Aug. 13, till Friday, Aug. 17. On Monday a reception will be held by the Mayor in the town hall, and visits will be paid to the works of Messrs. Swan and Hunter, and to those of the Electric Supply Company. On Tuesday Messrs. W. G. Armstrong, Whitworth, and Co.'s Elswick works, the engineering department of Durham College of Science, and the works of the Newcastle and District Lighting Company will be visited; and on Wednesday a trip will be taken down the river to inspect the Tyne Commissioners' works. On Thursday a visit will be paid to the works of the Wear Commission, and on Friday the United Alkali Company's works and the Corporation tramway works will be inspected. The summer dinner will take place at the County Hotel on Friday, the president (the Hon. C. A. Parsons, F.R.S.) in the chair.

Loud-Speaking Telephones.—Those who listened to the paper on "Wireless Telegraphy" which Dr. Lodge read some time ago at the Institution of Electrical Engineers, could not fail to have been struck by the way in which his telephones in relays gradually increased the sounds, and finally made a very loud noise indeed. An Hungarian has apparently hit on something the same principle, and the *Daily Mail* publishes an interview with him, in which he explains that he has nearly brought his instruments to such perfection as to telephone 1,000 miles, and at the far end to speak very loudly. His invention, he thinks, would be a great improvement on the electrophone, as instead of holding the telephone to the ears, one can sit and listen to all that is happening at the theatre in the same way that the sound in the phonograph can be heard. The inventor also hopes to use the system on board ship. The captain will be able to sit in his cabin and speak his orders to the crew, while the machine is roaring them out 10 times more loudly on deck.

Electric Traction and Trees.—We gather that complaints have been made against the new underground electric railway in New York, the reason given being that the excavations for it are hurting the trees in the streets. This is a variation of the usual lament that the overhead trolley is injurious. As to this matter one cannot speak with authority, but it is curious that while such complaints are being made, in Ireland electricity is said to have such a good effect on plant life that potatoes can be grown by the bushel where they previously only grew by the peck, in consequence of an arrangement of electrical circuits being conducted through the crops. The present complaint is, however, made before the railway has really had time to do much damage even by excavations, and it is difficult to see in what way the damage is effected. An American contemporary in mentioning the matter remarks that possibly the fading of the trees is caused by an entirely different cause—namely, the leakage of gas from the gas-mains. Our contemporary remarks that if this is the case, the obvious remedy for the killing of the trees is the use of electricity instead of gas for lighting.

Boston New South Station.—The paper read by Mr. Walter C. Kerr, entitled "The Mechanical Equipment of the New South Station, Boston," before the American Society of Mechanical Engineers, New York, has been reprinted and issued in the form of an attractive booklet by the British Westinghouse Electric and Manufacturing Company, Limited. We have received a copy of the paper, and in it a full and clearly-written account is given of this large well-equipped railway station. At the close of last year 737 trains were entering and leaving the new station daily, 65 of these within an hour in several instances, and in one case six trains depart and three arrive in less than two minutes. The equipment, which was entirely supplied by the Westinghouse Company, has been divided in the paper into 12 parts, and each of these parts is dealt with in detail. The divisions consist of the power-house, interlocking switch and signal system, the electric plant, heating and ventilation, disposal of drainage, roof drainage, icemaking, refrigerating and water-cooling plants, car-heating in sheds and yards, air-brake charging, steam and hot-water supply, fire protection, baggage and express lifts and elevators. The article is well illustrated, both from photographs and sectional drawings, and it should be worth the while of engineers in general to obtain a copy.

Automatic Tramway Brakes.—The report of the New York State Board of Railroad Commissioners has just been published on official tests made with automatic brakes for street railroad cars, to take the place of the old hand brakes such as are now mostly used in New York. The Board states that while nothing has been brought forward that will revolutionise the manner of stopping a car, the opportunity is afforded to present to the railway officers and to the public facts and figures showing what the best appliances known can do in the matter of stopping a car quickly. While the results are stated to be very satisfactory, there is still room for much improvement. After carefully considering the various points in each system and adding to or taking from the mechanical standing of the different brakes, as given in the report of the electrical experts, the Board gives the several brakes their proper order of merit, the Electric Selector and Signal Company, the Peckham Motor, Truck, and Wheel Company, and the Sterling Supply and Manufacturing Company being the first three. Their value, however, alters considerably in accordance with the work they have to do, and the order given cannot be looked upon as absolutely correct for every circumstance. On the subject of electrical brakes the Board consider that in almost every case these should replace the hand brakes now used.

Institution of Electrical Engineers.—The river party to which the American guests of the Institution of Electrical Engineers are invited will be given at Henley, electric launches taking a short run (probably to Shiplake and back) before the lunch, which will be at The Red Lion. After lunch the party will proceed to Boulter's Lock by launch, and will return to town by train from Maidenhead. The dinner on Aug. 13 will be at 7 for 7.30 p.m. at the Princes' Restaurant, Piccadilly. During the morning of the same day visits will be made to the laboratories of the Board of Trade, or (alternatively) to the Telegraph Department of the General Post Office, and in the afternoon to the Central London Railway and to the Davies-street station of the Westminster Electric Supply Corporation. On Aug. 14 the party will visit the School of Military Engineering and the Royal Dockyard at Chatham, and will partake of the hospitality of the Royal Engineers' mess at lunch. The members of the party have been most kindly invited to a reception by Lady Fraser in the afternoon. With respect to the grants of £5 to students of the Institution towards the expenses of a visit to the Paris Exhibition, which we announced in a previous issue, the following students of the Institution have been selected: J. F. Avila, A. Buckney, F. H. Clough, R. Fisher, A. J. L. Hurst, J. T. Irwin, T. L. James, F. K. Jewson, L. R Lester, C. N. Nettley, R. L. Pearson, M. Solomon, C. T. Stephenson, H. J. Thomson, W. A. Toppin, A. J. Tracey, S. A. Tunbridge, G. E. Turnbull, J. H. West, F. P. Whitaker.

Telegraph Engineers.—The annual conference of the Amalgamated Association of the Postal Telegraph Engineering Department was held at Leeds on Monday. The chairman was Mr. T. Landrick, of Leeds, and delegates

Digitized by Google

were present from most of the principal telegraph centres in the kingdom. The general secretary, Mr. George Young, of Northwich, reported that the association was in a stronger position then than it had ever been, this being mainly due to the increased membership. The expenditure had been unusually heavy owing to the large amount paid to the joint committee of the federated associations, but the committee had undoubtedly done excellent work. It was owing to the action of the committee that their claims had been brought before the House of Commons by Mr. Steadman. Since the last conference both Cardiff and Belfast had seceded from the association, although repeated efforts had been made to retain them. It was hoped that both these districts would return to the association. During the year they had had the welcome addition of Edinburgh, Coventry, and Holloway, all of whom had proved warm supporters of the cause. Holloway was exceptionally strong, and was making vast strides. A paper dealing with the Holloway men's grievances had been forwarded early in the year to the proper quarter, and much good was expected as the result. The officers for the ensuing year were afterwards elected, and several matters of importance to this branch of the postal telegraph service were discussed. It was decided to hold the next conference in Birmingham.

Technical Education.—In the *Technical Education Gazette* for July are given the full particulars of the special courses which have been arranged by the Technical Education Board of the London County Council for the coming session at University College, King's College, and Bedford College. At the University College, Gower-street, a course of 10 lectures intended for those engaged in the electrical or allied trades is to be given by Prof. J. A. Fleming, F.R.S. This course will comprise a theoretical and practical treatment of advanced methods in electrotechnical measurements, of the character required in electrical works and factories, in connection with electric lighting and electric power transmission. They will cover such subjects as the measurement of resistance, current, potential or E.M.F., electrical power, energy, and alternating-current measurements (single and polyphase). The lectures will be given between Oct. 17 and Dec. 19, the fee for the course being 5s. A course of lectures by Prof. Carus Wilson on the "Electric Motor and its Application to Electric Traction," will also be given between Jan. 23 and March 20 next, the fee being the same as in the previous course. At King's College, Prof. E. Wilson will deliver a course of lectures dealing with "Direct and Alternating Currents," the lectures commencing on Oct. 8, the fee being £1. 1s. The syllabus includes practically every point connected with the working of machines for both direct and alternating currents. There are numerous other courses at both the above-mentioned colleges, including mechanical engineering, chemistry, civil engineering, etc. The classes at the Bedford College are for women teachers only.

Northern Tramways.—We notice in the *Newcastle Daily Chronicle* an article dealing with the progress of the tramway undertakings in the Newcastle and neighbouring districts. Thus it is announced that in a few weeks the inhabitants of Sunderland will be the proud possessors of of an up-to-date system of electric tramways. The first section to be completed is the Christ Church-Roker route; but although this part has been finished for a few days, and highly successful trials have been made, it was found impossible to open the route to the public on Bank Holiday, as was anticipated. The trials made on Tuesday last were again highly satisfactory, the cars and drivers negotiating the traffic, which is considerable on this route, with great success. The section was inspected by the Board of Trade yesterday, and, if passed, is expected to commence passenger traffic on Aug. 15. We also learn that steady progress is being made with the work of relaying and extending the tramway system in the borough of Tynemouth and adapting it to electric power. The new rails, on a broader gauge than those formerly in use, have been laid over nearly the whole route. The station buildings are finished and awaiting the installation of the machinery, which is now on its way to Tynemouth. The work of relaying the lines was commenced last October, but little could be done during the winter owing to the severe weather. At Darlington we do not find the same felicitous state of affairs, there being at present a deadlock in the negotiations which have been proceeding between the Corporation and the Imperial Tramways Company on questions of the supply and price of electrical energy, street widening, and laying part of the tramlines. Neither party shows any disposition to go back from the position they have taken up, and in the meanwhile the danger of the conflicting views seems to be an indefinite postponement of the improvement, and a consequent retarding of the now rapidly growing borough.

Electricity in Indian Mines.—An announcement was made by Lord Ribblesdale at the meeting of the Road Block Company last week to the effect that an arrangement has been made with the Mysore Government for the transmission of electrical power from the Cauvery Falls to the Kolar Goldfield. The scheme in question will be what one may well call a long-distance transmission scheme, as the power is to be conveyed some 100 miles. The company have adopted an arrangement with the Indian Government, by which we understand the cost of the transmission machinery is to be borne by the Government, and to be gradually repaid by adding a certain sum to that paid for the current. The amount of power which it is expected to use at first is about 4,000 h.p., and even with this the owners of the mines expect to save considerably, and think the cost per horse-power will be much less than with the system now employed. One of the great things in which a saving will be effected is in fuel, as this in India commands a very high price and is comparatively scarce. Another item which will probably be reduced will be labour, as it is well known that wherever electricity is used in place of steam the amount of labour necessary is lessened. Again, in the cleaning and repair of machinery a saving will be brought about. At present, we believe the details of the scheme have not actually been settled, but are on a fair way towards that end. It is, perhaps, natural that electricity, where obtainable, should be preferred to steam for use in mining operations, as, apart from the less amount of time required in attending to the machines, it is very handy, and a motor can be placed in almost any position and in places which it would be impossible for steam power to be available. This announcement is, we hope, only a precedent for a number of other similar ones, as in Northern India especially a great deal might be done with water-power plants for such purposes as that mentioned above.

Automobile Racing.—What promises to be a very interesting and novel automobile exhibition and race meet is, we learn, to take place at Chicago next month under the auspices of the Inter-Ocean Publishing Corporation. The tests, races, and exhibitions are to be held in Washington Park from Sept. 18 to Sept. 22 Races are to take place at night, and great preparation are to be made to illuminate the course for these events. On the opening day a grand parade of some 500 automobiles is proposed to take place, and visitors will be able

Digitized by Google

to examine them at close quarters. On the second day tests are to be made as to the general utility of the vehicles, when vehicles using different forms of power will be classed together, the competitions taking place between vehicles stated to have certain capacities, and the rewards will take place in the ratio of load and weight of vehicle. To test the practical manipulation of vehicles, a series of dummy figures will be introduced on the tracks, some constantly shifting, some remaining permanent as the vehicles pass through them, causing frequent and sudden stops and turnings, to show the safety of the vehicles in crowded thoroughfares. There will also be provided a section of extremely rough and uneven roads, with mud and holes, and country road ruts, with logs, stones, and obstructions, requiring short stops and turns, and including both up and down grades, corresponding to country roads and city streets. These tests, it is thought, will be of great value to the automobile industry. In addition to the above contests are others equally interesting, and after the races are over a grand prize of £200 is to be given for the most valuable invention in automobiles which shall have been practically demonstrated during the exhibition. In all, about £2,000 are to be offered in prizes. The exhibition should be a great attraction to holiday makers, and prove very interesting and of great use to makers and users of motor-cars both for pleasure or for business purposes.

The Pacific Cable.—A Blue-book has just been published by the Canadian Government dealing with the question of the Pacific cable. The book contains a large number of letters and telegrams respecting the interests of Canada and the other Colonies. The period covered by the Blue-book is the eight months from August, 1899, till April, 1900. In one letter Sir Sandford Fleming draws Sir Wilfred Laurier's attention to the unnecessary delay in constituting the Provisional Board of Commissioners, and the consequent time allowed to the Eastern Extension Company to agitate the Australian Colonies against the Pacific cable scheme and in favour of their own Indian Ocean scheme. He also states in another letter that there are many circumstances that have given rise to the impression that the home authorities have unduly favoured the monopoly in its opposition to Canada and the Australian Colonies. A large number of cable messages passed between the Canadian and Australian Premiers, arising mainly from New South Wales and Victoria favouring the Eastern Extension Company's scheme. On March 30 Sir Sandford Fleming issued an address from Ottawa "to the British people in the Australasian Colonies," pointing out the urgent need of the cable to draw the British people in the outer empire nearer together, by bringing Canada and Australasia into direct and less costly communication. He held, he said, that nothing could take the place of the Pacific cable, and he felt it to be in the interests of the British Empire that no new obstacle should be raised to obstruct the immediate accomplishment of that undertaking. While firmly holding to that opinion, at the same time he recognises that there could not be too many cables if they were judiciously established to meet public needs. He was, therefore, unable to see any great reason for objecting to the Cape-Australian cable provided full provision was made for bringing it at any time when required under State control. Under State control it would, in conjunction with the Pacific cable, constitute the major portions of the great Imperial telegraph system.

The Lead Accumulator.—The current number of the *Journal* of the Chemical Society has the following abstract of a paper by Martin Mugdan in the *Zeitschrift Elektrochemie*: "The author shows that, when an accumulator is discharged, lead sulphate separates on both the positive and negative plates in almost theoretical quantity, and that no lead oxide is formed. If sodium sulphate is used as the electrolyte in place of sulphuric acid, however, some lead oxide is formed on the positive plate. A partially-oxidised negative plate takes up sulphuric acid very slowly, whereas a positive plate containing oxide absorbs the acid very rapidly. The potential difference between a negative (spongy-lead) plate and sulphuric acid of given concentration is independent of the quantity of lead sulphate on the plate. The alterations in the E.M.F. of an accumulator during charge and discharge are due to local changes of the concentration of the acid at the electrodes. When at rest the condition of affairs may be represented thus: $Pb,PbSO_4$ | acid | $PbSO_4.PbO_2$. During charge the acids at the electrodes are more, but during discharge, are less concentrated than the main bulk of the acid. The total E.M.F. is therefore obtained by superimposing the E.M.F.'s of two concentration cells on the main E.M.F. The two concentration cells may be represented thus: $Pb,PbSO_4$ | dil. or conc. acid | acid | $PbSO_4,Pb$ and $PbO_2.PbSO_4$ | dil. or conc. acid | normal acid | $PbSO_4,Pb$. The E.M.F.'s of these concentration cells are calculated from Nernst's theory, and compared with actual measurements made by the author. For acids containing less than 0·75 grm.-mol. per litre, the agreement is excellent. A change of concentration at the lead dioxide plate makes about 1·4 times as much difference in the E.M.F. as an equal change at the lead plate. Further, the concentration of the acid at the lead dioxide plate increases or decreases during charge and discharge $1+^{2v}/_{u}$ times as quickly as that at the lead plate (u and v are the relative mobilities of the H and SO_4 ions). The effect of the changes of concentration at both electrodes is to diminish the E.M.F. of the cell during discharge and increase it during charge."

A Flourishing Industry.—The condition of the electrical industry continues in Germany, as elsewhere, in a flourishing state. The principal manufacturing firms are without exception able to render excellent accounts of themselves, hence the rosy report of the Allgemeine Electricitäts-Gesellschaft, both with regard to its actual and prospective accomplishments, may be taken as a fair indication of the general state of the electrical industry in Germany. From this report it appears that the electrical industry has continued to develop satisfactorily, despite the increased price of raw materials and the tightness of money. The practical utilisation of blast-furnace gas has had a beneficial influence upon the construction of large dynamos as has also the rapid increase of high-tension installations, since the problem of running alternating and rotary current machines in parallel was satisfactory solved. The manufacture of small motors has also developed to a greater extent than anticipated. As regards the anticipated influence of the electrical industry upon the construction of machinery in general, this has showed itself in the perfecting of the power motor not less than in the transition to quick driving. In this connection, and having regard to the present coal famine, the solution of the problem of appreciably increasing the efficiency of the steam-engine would be greatly welcomed. According to experiments made at the Berlin Technical College the output of steam-engines might be increased by more than 50 per cent. without a greater consumption of steam. Last year 12,987 dynamo machines and electromotors, representing an aggregate output of 200,000 h.p., were turned out by the Allgemeine Electricitäts-Gesellschaft, besides enormous quantities of arc lamps, measuring instruments, switch gears and meters, etc. In continuance of their endeavours to perfect the Nernst lamp, the firm has introduced further improvements

Digitized by Google

in detail. The latest form of this lamp has, we understand, given satisfactory results after exhaustive tests, which fact has encouraged the firm to make extensive preparations for its manufacture in bulk, so that its early advent on the market may be expected. So far as the production of dynamo machines is concerned, another German firm—namely, Schuckert and Co., of Nuremberg—is able to show even better results for 1899. During the year in question, this firm turned out dynamo machines having an aggregate output of no less than 257,000 h.p., besides 14,000 arc lamps, 17,600 ampere-meters, 205 searchlights, 12,600 voltmeters, and transformers having an aggregate capacity of 15,500 kw., etc., all of which figures show a considerable increase over those for the previous year. As has been pointed out before, and may be pointed out again, practically unlimited capital has contributed mainly to these splendid results. It is to be regretted that the conditions in this respect here do not approximate more closely to those holding in Germany, for it is discouraging to see the development of home concerns retarded for the want of capital judiciously employed.

A Typewriting Telegraph.—Three patents have, we learn, been issued to Mr. Donald Murray, of New York, for an improved form of page-printing telegraph, employing an ordinary form of typewriting machine. The invention combines a recording instrument having a series of independently movable character levers, an electromagnetic perforating instrument, and a tape of paper, which passes through the perforating and recording instruments in succession. The perforator is connected with either a manual or an automatic transmitter at a distant station by a main-line telegraph wire, and a mechanical actuating device is provided whereby the perforated tape is enabled to operate the typewriter or similar instrument. At the receiving station the type machine is provided with a series of independently movable keys, each of which imprints a letter. To operate the typewriter, an actuating device, consisting of a series of notched bars or combs arranged compactly in parallel order and having a capacity for reciprocating motion, is employed, the power being supplied by an electric or other motor. The reciprocating combs are controlled by the perforated tape, which is divided into a series of successive longitudinal sections—say ½in. in length. Each section represents a letter or character, and is divided into a predetermined number of elemental parts. Each subdivision is either perforated or non-perforated. The perforations are arranged in a straight line, and the relative location of one or more perforations in any section determines the letter. The tape is moved along section by section across the ends or terminals of the reciprocating combs of the actuator. The actuator operating to press the perforated slip into contact with the ends of said combs forces one, two, or more of them to take the desired position, properly aligning the slots in the edge of the combs to permit the immediate subsequent operation of the desired one of the series of type-bars of the machine whereby the letter is imprinted. The transmitter, located at the distant station, throws upon the line short current impulses, which operate an electromagnetic perforator at the second station. The tape is fed along through the perforator, and the act of perforating and spacing is the result of a single current impulse of either positive or negative polarity. At the receiving station there is located an electromagnet, operated by a neutral relay in the main line. The armature of the magnet is spring-retracted, and a bar carried by it is in position to engage a simple form of paper punch or perforator. There is a finger capable of being projected in and out between the end of the bar and the end of the punch. When this finger is withdrawn, the armature fails to engage with the punch, and the paper is advanced one step, while the perforator is not operated. This finger or intermediary is controlled by a polarised electromagnet in the main-line circuit. A series of makes and breaks of negative polarity operate the step-by-step mechanism, and the paper is fed along without perforating, while one or more positive current impulses project the finger between the armature and punch, and perforate and space the paper. Each current impulse, whether perforating or spacing, moves the paper a single subdivision, or about ½in.

Cardiff Lighting.—We are sorry to see that, in spite of the power to control the whole of the electric lighting installation which the Cardiff Lighting Committee reluctantly gave Mr. Appelbee a short while since, the friction has not by any means ended. It is, however, this time not between the Lighting Committee and their engineer, but between various members of the staff. Last week, at the meeting of the Lighting Committee, the applications of five members of the staff for increased salaries were considered. In discussing the matter, Mr. Appelbee mentioned that the committee might be interested to know that five members of the staff were seeking employment elsewhere. This brought forth the remark from the Chairman that until the whole of the old staff had been cleared out they would not be able to do anything with the undertaking. Much surprise was, however, expressed when a letter was read from the mains superintendent, who was appointed only last June, also tendering his resignation. The committee questioned Mr. Appelbee on this matter, but however much he knew of the causes leading to the resignation he wisely left it to Mr. Illingworth himself to make all explanations. This gentleman, who could not be found at that particular time, was examined by the committee on Friday last at a meeting held specially for that purpose. The reasons Mr. Illingworth gave for his resignation appeared to be that he was greatly annoyed by the deputy engineer not allowing him to do his work in the way he thought best. He had also made representations as to the faults in the mains, sub-stations, junction boxes, etc., but these had not been remedied, or only very tardily. In this way he could see that in the winter many breakdowns would occur, and his reputation would suffer. The men also who were under him were inclined to be slovenly, and would not do so much work as they should have done. The matter, however, on which the mains superintendent felt most strongly was the interference of the deputy engineer, and Alderman Ramsdale remarked on this point that the agreement of Mr. Illingworth distinctly stated that Mr. Appelbee was his chief, and he did not see why he should be interfered with by the deputy engineer in any shape or form. The agreement intimated that Mr. Appelbee was the only authority. In reply to the criticisms on the management, Mr. Appelbee said he took entire responsibility for the outdoor department, and Mr. Illingworth was only responsible to him. He had received no complaint of the design of the junction boxes, and in regard to the water in the stations the repairs were kept for the public works man to do, and he was on his holidays. There was no danger, and the water was easily kept down. The necessary switch gear for the distributing stations had been ordered, and there was no difficulty in having all that Mr. Illingworth proposed done by next winter. Mr. Appelbee further told the committee that they were responsible for the appointment of the deputy engineer. He had not recommended him, and did not do so then. The final outcome of the meeting was that Mr. Illingworth withdrew his resignation pending a general enquiry which the committee is to hold.

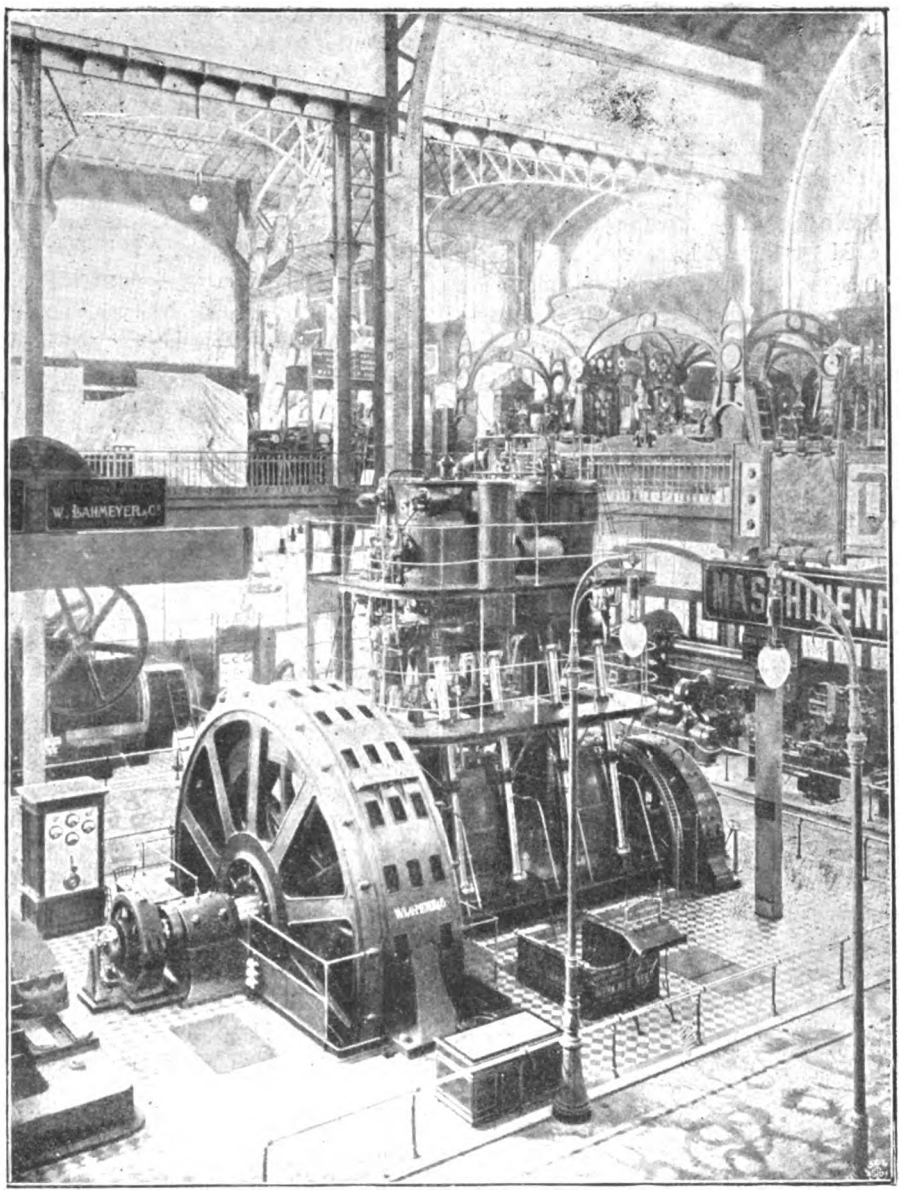
THE PARIS EXHIBITION.

[BY OUR OWN CORRESPONDENT.]

(Continued from page 121.)

The electric exhibit of Messrs. W. Lahmeyer and Co., of Frankfort-on-Main, consists of a 1,500-h.p. compound steam-engine running at 94 revolutions per minute, and two dynamos, one for 1,000 kw. three-phase current at 5,000 volts, the other for 400-kw. (maximum) at 500 volts; both are coupled directly to the engine shaft.

The three-phase generator is of the flywheel type—*i.e.*, the field magnets are fixed on the periphery of the flywheel and the armature on a large frame, which completely encloses the field magnets. The diameter of the rotating part is 5,800mm. (=18ft. 3½in.); the diameter of the centre of gravity of the rotating part, 4,730mm. (=15ft. 6½in.); the energy of the flywheel is 1,018,000 kgm. (= 24,117,000 foot pounds). The speed variation during one revolution is one three-hundredth of the normal speed only. By this combination of dynamo and flywheel it is claimed that the space required for the set is minimised, the material is almost entirely utilised, the magnetic leakage and the armature reaction are very small, and the ventilation is excellent and efficient. The flywheel consists of four pieces held together by bolts and wrought-iron rings. The magnets are of wrought iron, and are fixed by one wrought-iron bolt and one steady pin each, so that each magnet can easily be removed, rendering it unnecessary to dismantle the dynamo. The cross-section of the magnet is circular, so as to give without any excessive pressure drop a minimum of the winding length and, consequently, of loss of energy in the coils. The pole-pieces are almost square, so as to reduce as much as possible the magnetic leakage. They are of solid wrought iron, thus giving a more substantial construction than laminated magnets, and rendering any resonance impossible when the machine is working in parallel with other machines. The eddy currents generated in the magnets help to prevent a "drive" on the machines by their damping effect. Excessive heating of the machine is prevented by great attention to obtain correct dimensions of the air-space and a suitable form of slots in the tunnel-wound armature. Each coil is formed by a rectangular copper ribbon, the width of which is normal to the surface of the magnet. The insulation consists of paper. By so wiring, the space of the magnet is well utilised, and a deformation of the coil by the effect of the centrifugal force is practically obviated. The exciting current is generated by an exciter mounted on the same shaft as the main dynamo, giving 65 volts. The voltage of the three-phase generator is regulated by inserting resistance in the fields of the exciter, this arrangement doing away with the heavy resistances usually employed in the main circuit, so avoiding loss of energy and all risks of heating at the back of the switchboard. The armature is stationary and consists of laminated iron, the segments of which are held together by bolts in a cast frame. Two end plates, reinforced by radial arms, render impossible any vibration of the frame, so that the machine runs almost without noise even at full load. The armature generates current at 5,000 volts between the outers, and is wound in micanite tubes which have been subjected to an insulation



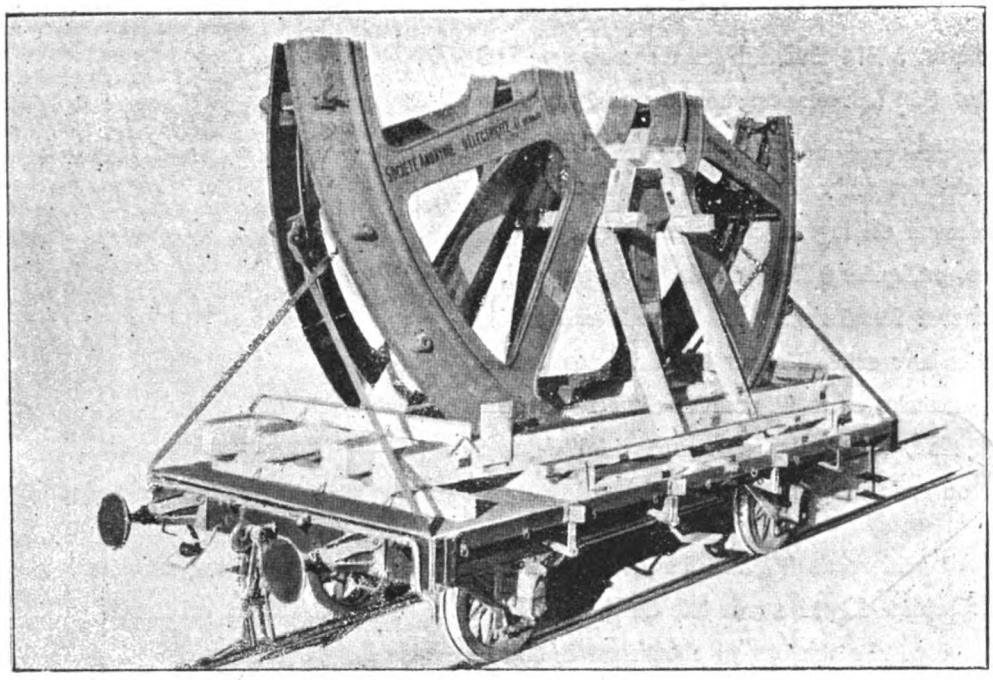
General View of Messrs. W. Lahmeyer and Co.'s Exhibit at Paris.

Digitized by Google

resistance test at 10,000 volts. The tubes and the slots are of circular section. This secures a good insulation, and at the same time the hysteresis and eddy-current losses in the teeth are minimised. The energy losses are as follows:

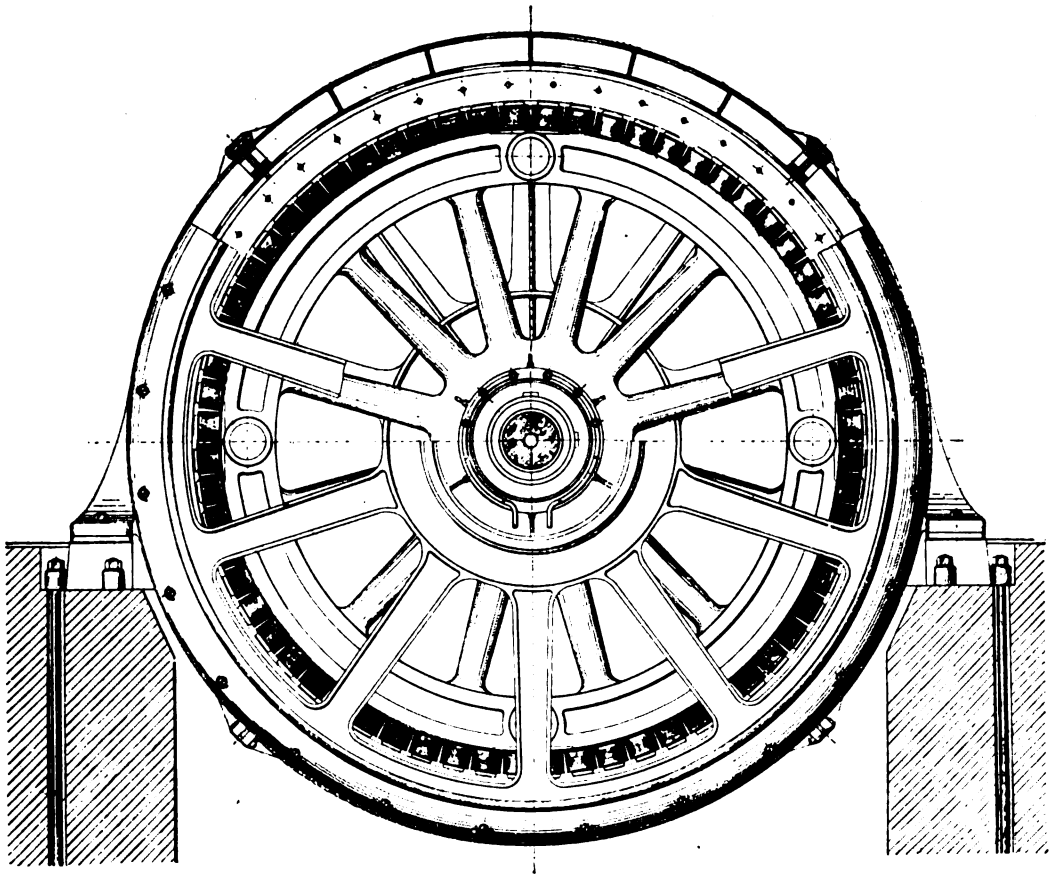
Power absorbed by armature copper.....	13,700	watts.
,, ,, ,, ,, core.....	13,100	,,
,, ,, ,, ,, teeth.....	9,100	,,
,, ,, ,, ,, excitation.....	13,800	,,
Total	49,700	watts.

The electric efficiency is therefore 95 3 per cent. at full load (non-inductive). Special attention has been given to secure a small drop in voltage between full and no load. It is about 6 per cent. for non-inductive load. This result is attained by a strong magnetic field and high saturation of the magnets. The short-circuit current is about 3.5, or four times the current at full load for a constant excitation. The magnetisation of the iron is always beyond the bend of the curve.



Method of Transport of Dynamo Frames.

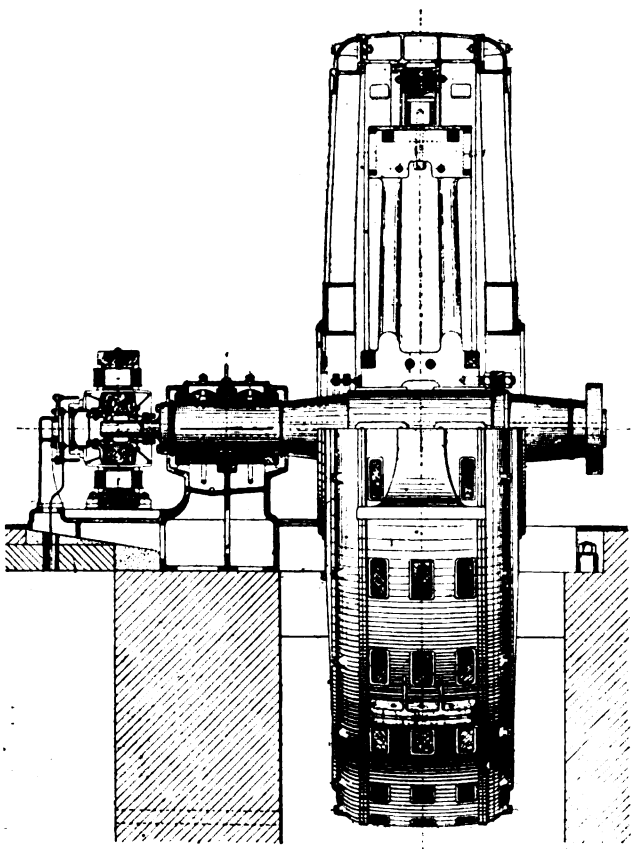
The method of arranging the measuring instruments is patented by Messrs. W. Lahmeyer and Co., Limited. This arrangement excludes any possibility of an accident to anybody in proximity to the instruments, as all readings are taken off a low-tension circuit. In each phase one of the armature coils is separated from the others, and is connected with the primary windings of a special transformer (ratio of windings, 1 : 1), the secondary windings of which are in series with the rest of the coils. All readings are taken in the primary windings, the amperes in these being the same as in the machine. The voltmeter is



Cross-Section of Dynamo.

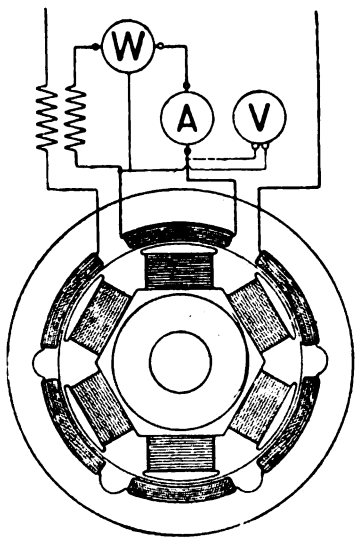
Digitized by Google

calibrated so as to give the voltage of the one coil multiplied by the number of coils, thus giving the voltage of the dynamo. This arrangement gives very exact readings, and the difference of the air-space at the different coils does not influence in any appreciable way the accuracy] of [the] readings. This arrangement has been



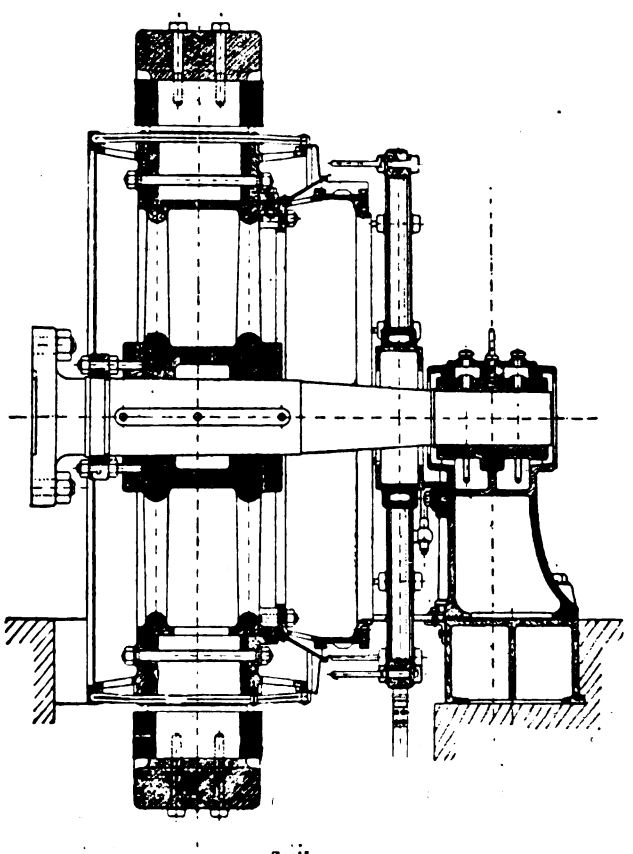
Section of Dynamo.

applied to many machines built by Messrs. W. Lahmeyer and Co., Limited, and has given entire satisfaction. The shaft of the combined set is made in three pieces coupled together by ordinary flanged couplings. The exciter armature is wound on the end of the shaft which extends beyond the extreme bearing on the three-phase side of the set. The exciter fields are bolted to a bracket fitted to the pedestal.



Arrangement of Circuits.

As we have seen above, a direct-current dynamo is coupled to the engine shaft on the other side. This dynamo is built for a normal capacity of 400 kw. at 500 volts and revolutions per minute. The dynamo is of the multi-per type. The yoke consists of two semi-circular parts, on wh 12 cast-steel poles are held, each by two iron bolts. The les and pole-pieces are cast in one piece. The armature of the drum type, and is bar wound in two layers in 609 milled slots, which are insulated with mica. The armature is not banded in the ordinary way, but the conductors are secured by small brass strips, which are held on the periphery by pins. At the back end of the armature all connections are in a piece with the conductors, the bars having been bent on a special former, so that the number



Section.

of sweated joints is reduced to a minimum. The method of fixing the winding by these strips facilitates removal of a damaged bar. The commutator is built up of cold-drawn copper segments with mica insulation. The brush connections are fixed on an I-shaped ring, and are well insulated by ambroine. All screws of the brush-holder which can possibly be got at from the outside are protected by caps of the same material. This machine has been designed for traction work, and is specially adapted for severe overloads and sudden variations of the load without sparking of the commutator. Even at 440 volts—the pressure used at the Exhibition—no rocking of the brushes is necessary. The diameter of the armature is 1,400mm. (=about 55in.), its length 400mm. (=15$\frac{3}{4}$in.). At full load and 530 volts the mechanical and electrical efficiency is 93·2 per cent. The power absorbed by the armature copper is 2 per cent., by the excitation 1·5 per cent. There is very little heating, the rise in temperature being only 30deg. C. for the armature iron and 25deg. C. for the induction coils. The saturation of the iron is such as to give (at constant excitation) a difference in voltage of 10 per cent. only between full and no load. For starting the engine the following arrangement has been devised. A toothed disc has been placed on the shaft, which is engaged by a small pinion driven by a 7-h.p. motor (220 volts, 700 revolutions). This switch pinion disengages itself automatically as soon as the machine is started.

The steam-engine was supplied by the Maschinenbaugesellschaft, Nürnberg. It is a vertical two-crank engine, and develops 1,700 i.h.p., or 1,500 effective horse-power, at 10 atmospheres (147lb. per square inch). The engine is provided with a jet condenser. It is bolted to a bed-plate which consists of two parts. Each part is cast in one piece with two bearings. The shaft has a coupling at both ends for connection with the dynamos. The diameter of the high-pressure cylinder is 865mm. (=34$\frac{1}{16}$in.), and that of the low-pressure cylinder 1,350mm. (=53$\frac{1}{8}$in.), with a stroke of 1,100mm. (=43$\frac{5}{16}$in.). The two air-pumps are driven from the

Digitized by Google

connecting rod by means of a beam with a diameter of 670mm. (=26⅜in.), and a stroke of 350mm. (=13¾in.). The approximate weights are as follows: steam-engine, 120 tons; three-phase dynamo, 124 tons; direct-current dynamo, 31 tons—total weight, 275 tons.

At the Exhibition the oil is supplied by the Vacuum Oil Company, of New York. A serious difficulty was experienced for the transportation of the three-phase dynamo frames. The way in which this difficulty has been overcome is graphically illustrated on the annexed figure. In consequence of the high pressure at which current is generated in the three-phase machine, many very distant points in the Exhibition are illuminated by its agency—for instance, the Alexander Bridge and the main portal of the Exhibition.

(To be continued.)

THE EVOLUTION OF SWITCH GEARS FOR HIGH-PRESSURE ALTERNATING CURRENTS.

BY W. E. WARRILOW.

INTRODUCTION.

The equipment of an alternating-current station with an efficient switching apparatus is a most important problem, and when compared with the continuous-current system, the importance is greatly increased by reason of the higher pressures employed, and consequently the difficulties encountered in the provision of effective means of quenching arcs in fuses and switches. A glance at the development of the high-pressure switch gear will no doubt prove of some interest, not so much on the grounds that anything new will be said on the subject (except, perhaps, in dealing with the later types), but that a collecting together of the various forms of gear employed will afford excellent opportunities of comparison, and illustrate the many advances in construction. The rapidity of these advances may be said to have brought about a distinct revolution when compared with the progress of other mechanical apparatus, and when a look is taken at the later types of gear, it is hardly possible to credit the statement that the older examples were in use within such recent times.

In the early days of alternating-current supply, the attention of electrical engineers was almost entirely devoted to the perfection of the generator and its engine, the switchboard problem being considered of a simpler nature. It was accordingly constructed on the most primitive scale. When compared to the dynamo, and considering the demands made upon it, the wonder is that more accidents and "burn outs" did not occur. However, since the construction of dynamos and engines has more or less settled down to standard direct-coupled types, the controlling apparatus has received a greater amount of attention in proportion to its importance, with corresponding excellent results. One of the questions which an engineer of a few years ago had to answer was, What form shall the switch gear take?—*i.e.*, there were two distinct types open to his choice:

1. The isolated gear, generally consisting of a panel or pillar placed (either on a gallery or the floor) opposite each machine to which it was connected.
2. The collected gear, in which all the apparatus was concentrated into a comparatively small space.

Each had their adherents, and the advantages or otherwise of each were as follows:

For the isolated gear it was said that, in case of prolonged arcs and the setting fire to a panel, the disaster was confined to the apparatus controlling one machine, the other units being unaffected thermally, if not electrically. In handling the connections which had been made "dead," there was no possibility of coming in contact with other "live" panels. Against the same gear it was urged that parallel running was rendered difficult by reason of the distance separating the panels; that in case a number of machines were running greater attendance was necessary; and that the scattered nature of the gear did not lend itself in any way to the ornamental appearance of the station. For the collected gear it was said that small space was occupied, parallel running was rendered more simple, less attendance was necessary, and when neatly arranged the apparatus presented an ornamental appearance, and added greatly to the *ensemble* of a station. Against this class of gear it was said that, in case of fire, the accident was liable to affect the entire supply in consequence of the destruction of the whole board, or the rendering necessary of the shutting down in order that the fire might be extinguished; that the connections at the back of the board presented a veritable death-trap to the electrician, who, though protected with rubber gloves on the hands, might stumble against the terminals when working with bare arms, and, in the case of double-pole boards, come to grief. The danger of handling these connections becomes still more evident when it is considered that though the electrician would have made dead the panel on which to work, the proximity of "live" contacts greatly increased the possibilities of accidents.

In spite of the apparent advantages of the isolated gear (on the ground that the supply was less liable to serious interruption), it has developed up to a certain point and gone no further. This is due, not so much to its unsightliness (as it has been made very ornamental), but to the fact that the collected gear possesses more marked advantages, and can be made to meet all the requirements of the alternating-current engineer. The most important developments have taken place with this form of apparatus, and so satisfactory have they proved that the concentrated gear may be said to have come to stay.

It will be seen that the engineer had no mean problem to solve in the provision of a good switchboard for his station in years gone by. His choice of apparatus was very limited, and the conditions to be fulfilled so important, that in some cases the board was designed by the engineer to meet his own special requirements. However be the arrangement of the gear of the isolated or collected class, the switchboard consists essentially of two distinct yet inseparable forms of gear—that dealing with the high-pressure alternating currents, and that controlling the low-pressure or exciter currents. The former is by far the more important of the two, and has presented enormous difficulties in the way of construction, and the latter has proved of equal importance almost, save that more information has been to hand, consequently the difficulties have been more readily overcome. The high-pressure portion of the gear will consist of panels containing fusing, switching, and recording apparatus for a certain number of dynamos and circuits, also the synchronising and pressure recording instruments. The low-pressure section will be fitted with switch ammeter and rheostat for dealing with the currents from the exciter to the alternator field.

The development of these various types of gear has not taken place with any degree of uniformity, so that the improved examples of each type seldom found their way to any one switchboard. The means of controlling the exciter currents on a board might be of a most effective nature, but the high-pressure circuits would be dealt with by dangerous and inefficient apparatus, or the opposite might be the case. It is not until quite recently that efficient apparatus of both sections have been combined on one switchboard. In dealing with the evolution of high-pressure switch gears, it will be necessary to describe well-known types of apparatus, so that nothing particularly new may be looked for in the following lines; but the principal object aimed at will be an illustration of the progress made, and the degrees of safety or efficiency heretofore unattained or unattempted which have been reached. Comparison is the only method available in such a description, so that when the accounts of the earlier examples of gear are perused, they must be taken as necessary to the object in view rather than as illustrations of apparatus hitherto undescribed. The practice of American and Continental engineers will not be dealt with, as it can be said with truth that their designs have had no marked effect on the manufactures of electrical engineers in this country. Moreover, the subject in hand will occupy quite sufficient space without discussing the work of engineers in other countries, whose labours alone

Digitized by Google

would fill a large volume if considered apart from the work of others.

The descriptions following will apply to apparatus used in connection with switchboards for dealing with currents at 2,000 volts pressure, as this voltage has been most commonly adopted in this country, consequently a greater amount of information is available concerning gears controlling it. Extra high-pressure stations, however, do exist, but as the difference in arrangement is mostly one of insulation, the few examples extant will be considered as having no direct bearing on the subject. The drawings are diagrammatic solely, and do not necessarily represent precise details of construction, as they are given to illustrate the principle of the apparatus described. The leading types of switchboard will be dealt with, and the accounts of each will include the high and low pressure gears, as if the description of each section be kept separate, the main object of illustrating the growth of the complete gear will be defeated; moreover, if both are considered together, the statement made above, that the progress of each has not been uniform, will be borne out.

(To be continued.)

SOME NOVEL INVENTIONS OF NIKOLA TESLA.

BY J. WRIGHT.

Most members of the electrical profession associate the name of Nikola Tesla with high-frequency and high-potential currents, and few are acquainted with the fact that he has also invented several novelties for use in other branches of the profession. It is of some of these extraneous productions that I purpose treating in the course of this paper.

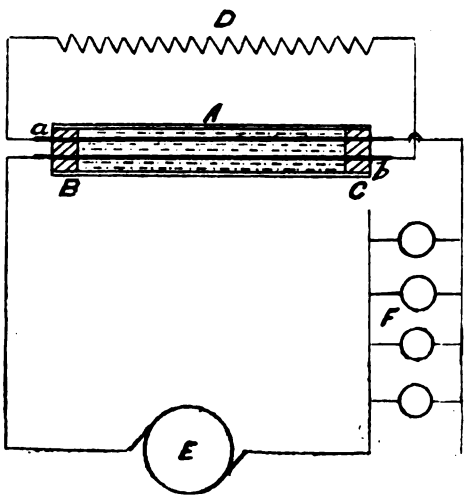


FIG. 1.

The first item consists of an electrolytic meter, the principle underlying the action of which is as follows: A conductor is immersed in a metallic solution, and the current to be measured is passed through it. The action of the current in passing is to remove from or deposit on the conductor a certain quantity of metal, and by so doing alter the electrical resistance of the conductor, which can thus, if necessary, be caused to register automatically when the current passing rises above or falls below certain limits. Fig. 1 is a diagrammatic view of the apparatus. A is the glass containing tube of cylindrical form, sealed at each end by an insulating and watertight plug, B C, through which pass the leading-in wires; *a b* are the active conductors of the apparatus. They are placed parallel to one another throughout the length of the tube, A, and are connected in series through a resistance, D, with the generator, E, and energy-consuming circuits, F, in such a manner that there is an equal difference of potential between them throughout their whole length.

Under the conditions described above a current passing through *a* and *b* will establish a difference of potential between them proportional to the current strength. This gives rise to a leakage between them which is proportional to the potential difference, and therefore to the strength of the current passing through the conductors. Again, owing to the fact that there is a constant difference of potential between the two conductors throughout their entire length, the current density through the electrolyte will also be uniform, and as a natural consequence the metal will be removed at a uniform rate from one conductor and deposited at an equal rate on the opposite one, thus causing an alteration in their electrical resistances proportional to the strength of the current passing through them, from which given quantity the value of the latter can be readily ascertained—in the first instance by experiment, and in the second by comparison. It will be seen that this apparatus is somewhat similar in principle to that of Edison, with this difference—that the results depend in one case on electrical resistance, and in the other on actual weight.

The *modus operandi* of the apparatus is as follows: The two conductors, *a* and *b*, are first accurately gauged and measured for resistance, the results being carefully noted. A fixed current is then passed through the instrument for a certain time, and the respective diminution and increase in the resistance of *a* and *b* is then ascertained. From the facts thus gathered a constant is obtained whereby the instrument is rendered capable of accurately recording any succeeding currents which may traverse the active conductors, *a* and *b*. A test of its accuracy is provided by the separate measurement of the two conductors, when the gain in the resistance of one should equal the simultaneous loss in the other, or, as a further proof, the resistance of the two conductors measured in series with the resistance, D, should be a constant quantity. It is hardly necessary to mention that at certain intervals the direction of the current in the two conductors, *a* and *b*, must be reversed in order to equalise the metallic reduction and deposition respectively. The advantages appertaining to this form of meter are obvious: The readings can be made directly by means of an ohmmeter; the whole of the current may be passed through it provided that the gauge of the two wires, *a* and *b*, be sufficiently large, thus rendering the use of shunts and attendant inaccuracies unnecessary. The accuracy of the instrument is not impaired to any appreciable extent by temperature variations. Above all, it is a cheap form of apparatus for the purpose.

The next inventions with which I purpose dealing are

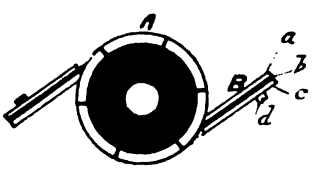

FIG. 2.

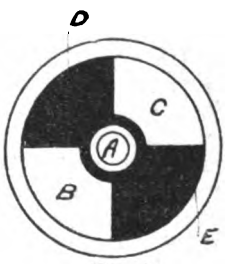

FIG. 3.

those involved in the manufacture of dynamo commutators and brushes, in which sparking is reduced to a minimum or even rendered impossible. Devices for the reduction of this generally necessary evil were no doubt suggested to Mr. Tesla by his marked antipathy to commutators of any description, brought to light by a consideration of his commutatorless motors. Fig. 2, which is a diagram of an anti-sparking brush device designed by him, will help to explain its principle. A is the end view of an ordinary continuous-current dynamo commutator, B being the brush, which is divided into three principal parts: *a*, the metallic brush, as usual; *b*, a plate of mica or other suitable insulating material, such as asbestos paper; and *c*, a flexible spring, which regulates the pressure of *b*, and is governed by the set screw, *d*. The principle of the device will no doubt be understood from its construction. The formation of an arc or spark between the brush, *a*, and the commutator segment which is just leaving it is prevented by the contact made between the insulating strip, *b*, and the corresponding insulating material of the commutator. In some forms of this brush two separate strips of insulating material have been introduced at *b*, instead of one, with advantage.

In another device designed with the same object in

Digitized by Google

view—viz., the elimination of sparking between commutator segments and collectors—both apparatus take the form of discs with their faces well surfaced revolving accurately against one another. Fig. 3 is a diagrammatic end view of the commutator disc of one of these devices. A is the dynamo shaft; B and C are the metallic sectors; D and E the corresponding sectors of insulating material, this being only a simple two-part commutator. The whole surface of the disc in Fig. 3 is accurately faced and smoothed, so that both metallic and insulating sectors are flush with one another. The collector disc is the facsimile of that shown in Fig. 3, but is not keyed to the shaft of the dynamo.

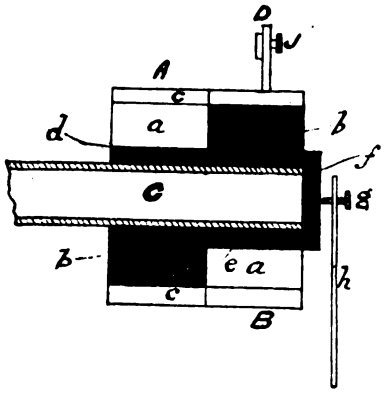

FIG. 4.

A general idea of the complete apparatus may be gained by a study of Fig. 4, which represents a longitudinal section of the commutator, A, and B, the collector; *a a* represent two metallic and *b b* two insulating sectors; *c c* are insulating rings which surround the outside edges of the sectors, and prevent a dissolution of partnership on the ground of centrifugal force; C is the dynamo shaft, through the tubular extremity of which are brought the wires from the armature coils; *d* is an insulating collar placed between the sectors and the shaft to prevent contact, and revolving with the latter; *e* is a similar insulating sleeve for the collector, and the dynamo shaft revolves inside it; a cap, *f*, is screwed on the end of this movable sleeve, and the pressure of a set screw, *g*, on the end of a stiff steel spring, *h*, serves to maintain good surface contact, between the commutator and collector surfaces; D is a quadrant for adjustment with a set screw, *j*, which takes the place of the ordinary brush-rocker, and serves to set the angle of the collectors. The advantages of this form of dynamo commutation will also be readily seen. The short-circuiting interval is reduced to a minimum by the simultaneous "make" and "break" of the sectors, which reduces sparking, besides increasing the efficiency of the machine.

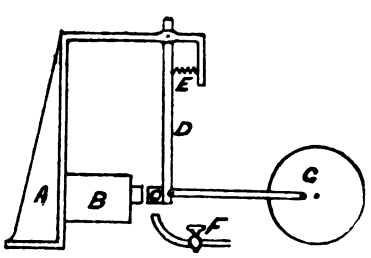

FIG. 5.

In another form of the same device a liquid—mercury, to wit—takes the place of the solid metallic sectors. The two discs are built completely of insulating material in this case, and in place of the solid metallic sectors cavities are left in their faces. The terminals of the collector end in airtight spring plungers or buffers, which serve to regulate the pressure of the mercury under the action of centrifugal force, and also to ensure a good contact between it and the terminal screws. In both forms the insulating blocks should be constructed of some durable material, such as glass or marble, whilst in the solid form the efficiency and durability may be augmented by facing the edges of the metal segments, between which the major portion of the sparking would tend to take place with some durable conducting material, such as platinum.

In the course of his electrical research, Tesla has not failed to study the subject of thermomagnetism, and as a result he constructed one or two rather ingenious forms of thermomagnetic motor, which are, however, for obvious reasons, still in an experimental stage. They are founded on the fact proved by Dr. William Gilbert at the beginning of the seventeenth century, that a magnet or lodestone when heated to redness is deprived of its magnetism. The principle underlying the device is illustrated in Fig. 5, in which A is a standard or support carrying a magnet, B, permanent or otherwise. C is an armature of the latter, forming the bob of a pendulum rod, D, supported above; E is a spiral spring which comes into play when the armature is demagnetised; F is a gas-burner or other suitable source of heat; and G is a wheel and connecting rod by which the power is converted into the ordinary form of rotary motion. Its action is as follows: The armature, C, is in the first instance attracted by the magnet against the tension of the spring, E. On heating C by means of the burner, F, it loses its magnetism and is drawn back by the spring out of the flame. On cooling, the magnetism again comes into play, and the armature returns to its original position, to be again heated, and so it goes on, the motion being of necessity somewhat slow.

There are several modifications of this motor, all working on the same main principle. In one the core of the electromagnet is made movable, and takes the place of the swinging armature, C, which is fixed. To the end of the magnet core it attached a shield, which, when the armature loses its magnetism and the core is drawn back by the spring in consequence, comes between the armature and the flame, and allows the former to cool by intercepting the

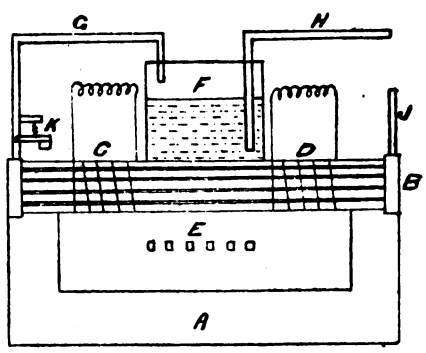

FIG. 6.

heat rays. In another form the armature rocks over the two pole-faces of a permanent horseshoe magnet spanned by a sheet-iron keeper, which latter is heated by a burner whose tap valve is controlled by the rocking armature itself.

A study of the reverse of these conditions also led Mr. Tesla to construct a pyro-magnetic generator based on the undermentioned laws: "Electricity, or electrical energy, is developed in any conducting body by subjecting such body to a varying magnetic influence. The magnetic properties of iron or other magnetic material may be partially or entirely destroyed or caused to disappear by raising it to a certain temperature, but restored and caused to reappear by again lowering its temperature to a certain degree." Tesla's apparatus for practically applying these laws is represented diagrammatically in Fig. 6. A is a permanent magnet, the poles of which are bridged across by a casing containing a number of iron tubes, B. Round this compound bridging-piece are wound the collecting coils, C and D, which serve to collect the current generated. E is a closed furnace surrounding the central portion of the bridging-piece, and surmounted by a boiler, F, the steam generated in which is conveyed to the tubes, B, in the bridging-piece by the pipe, G. H is the water-supply pipe, and J the exhaust. The admission of steam is regulated by a valve, K, under the control of the magnet, A.

From the several inventions dealt with above, it will be seen that Mr. Tesla has not confined his labours solely to the field of high frequencies.

THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

EIGHTH ANNUAL MEETING AT KIEL.

[BY OUR OWN CORRESPONDENT.]

(Continued from page 118.)

Another interesting paper read was that by Prof. Dr. Wedding, who described a new form of arc lamp called the Bremer, after Hugo Bremer, of Neheim, its introducer. According to the figures obtained by Prof. Wedding as the outcome of practical experiments with the lamp, it would seem to combine simplicity of construction and regulation with high efficiency. It is not my intention at present, however, to discuss the paper at any length, though it may be mentioned that the higher efficiency claimed over that possessed by the ordinary type of arc lamp is obtained by incorporating a larger proportion of non-conducting metallic salts, such as calcium, silicium, or magnesium, with the carbon used in the lamp, thus ensuring a better diffusion of the light. The figures given by the professor showed that a continuous-current arc lamp of the Bremer type taking 12 amperes at 45 volts terminal potential consumed only 0·13 of a watt per candle-power of light obtained, while an alternating-current arc lamp of the same type taking 5½ amperes consumed about half a watt per candle with the arc exposed. Prof. Wedding thinks it possible, however, to reduce the latter figure to that obtained with the continuous-current arc. The consumption of carbon by the new lamp is about double that which takes place in the ordinary type, but, in contrast to the blue-violet light yielded by the ordinary arc, the Bremer yields a light rich in orange and yellow-green rays. The lamp has four carbon pencils, between which the arc is formed. These pencils or rods are placed in pairs at an angle to each other. In order to form the arc one of the pairs of carbons is pulled away from the other by an electromagnet. As the carbon is consumed, the length of the arc is automatically regulated by the weight of the carbons and auxiliary weights attached to the same, thus obviating the necessity for any special mechanism. It is claimed that the Bremer type of lamp may be made to yield three times the volume of light given by an ordinary arc lamp with the same consumption of energy. This is, of course, a great feature in its favour, but it remains to be seen what actual success will be obtained by the new lamp. For the present it may be regarded as still in an experimental stage. The greater consumption of carbon compared with that consumed by the ordinary type of lamp is a serious drawback to its ultimate success on the market, but this may be overcome as suggested by Prof. Wedding. At any rate, the fact must be faced that the tendency of recent improvements in connection with arc lamps has been in the direction of retarding the consumption of carbon, and the long-burning qualities obtained must, therefore, be looked upon as essential and not secondary to the success of any new lamp.

A slight digression may now be made in order to give some interesting particulars relative to the employment of electricity in the German navy, which are contained amongst the printed matter distributed to those who took part in the meeting. From this source it appears that until the year 1890 electricity was only generally employed in the German navy for lighting the interior of the ships and for searchlights. It was first towards the middle of the year 1890 that electricity was extensively employed for power purposes in the German navy, when the coast defence vessel "Aegir" was provided with a comprehensive electrical equipment. The installation included nine primary generators designed to yield a terminal potential of 120 volts. Of these machines three had an output of 48 kw. each, and were driven by steam-engines, while the remaining six each had an output of 33 kw., being driven in pairs by three steam-turbines. Since first installed this primary plant has undergone some modification, consisting now of six units in all—viz., three steam turbo-dynamos of 48 kw. capacity each for working the gun turrets, and three steam dynamos for lighting and general power purposes. The plant is not all situated in one part of the ship, but in two different compartments, one of which is in the stern of the vessel. Each of the 48-kw. dynamos is of the multipolar compound-wound type, having six poles. The shunt winding consists of copper wire 2·9mm. in diameter, and is connected in series with a regulating resistance. The series winding consists of three layers of insulated copper strip, and is excited by the whole of the current flowing through the external circuit. The armature possesses 240 coils of copper wire 3·6mm. in diameter in two layers, while the commutator has a corresponding number of segments made of hard bronze from which the current is collected by means of copper brushes. Each of the three machines may be simultaneously employed for lighting and power purposes. The three turrets are each worked by a series-wound motor, which transmits its motion to the roller base of the turret by means of worm and toothed-wheel gearing, the motor obtaining its driving current from one of the compound-wound steam turbo-generators, which latter have also been successfully employed as auxiliaries to the other steam-driven sets for lighting purposes, and experimentally for supplying energy to the steering apparatus. The five ammunition hoists on board are calculated to lift an aggregate weight of 1,323lb. in 20 seconds to a height of 29ft. Each of the shunt-wound motors which work these hoists has an output of 6 h.p. when running at 800 revolutions and consuming 50 amperes of current at 120 volts terminal pressure. The power for driving the steering gear on board the "Aegir" is provided by two shunt-wound motors connected in parallel, which run in opposite directions to each other. When both are running at their normal speed—namely, 300 revolutions per minute—the toothed gear wheels revolve without actuating the rudder shaft. If, however, the speeds of the motors be varied relatively, this shaft is then turned in the direction of the quicker-running motor. By means of worm and toothed gearing this motion is finally transmitted to the rudder. The relative variation of the speed of the motors is accomplished through the steering wheels, the conductors to which are arranged in parallel with the shunt winding of the motors. At both sides of the centre position of the steering wheel three contacts are provided, over which an insulated contact arm, firmly attached to the hand lever, slides. These two sets of three contacts each correspond to three different speeds of the rudder shaft in the one or other direction. Moreover, the apparatus is so arranged that a turn of the steering wheel towards the right corresponds to a turn of the rudder to starboard, and *vice versâ*. The rudder may be turned through its extreme limit of action in 30 seconds. Mounted near the steering wheels are the instruments which indicate the position of the helm. These are nothing more nor less than voltmeters provided with a scale corresponding to the different angles of the rudder instead of volt divisions. The variation of pressure, which causes a deflection of the pointers towards starboard or port, is effected by a graduated resistance, whose sliding contact is connected to a pulley. In order to prevent an unintentional movement of the rudder, a regulator is attached to the rudder shaft, which automatically admits a flow of current through the shunt winding of the quicker-running motor, thereby equalising the speeds of the two motors. The capstan on board the "Aegir" is likewise electrically driven, a series-wound motor of 15 h.p. when running at 500 revolutions per minute being employed for the purpose. The gear for shipping and unshipping the boats is also electrically worked. Further, the windlasses used for raising the anchors are driven by shunt-wound motors, which, with 120 volts terminal pressure, a speed of 1,000 revolutions per minute, and taking from 25½ kw. to 38 kw., are each capable of developing from 30 h.p. to 45 h.p. For starting and controlling these motors a large resistance is placed near the anchors, while a smaller one is provided in the exciting circuits. There are also on board 10 electrically-driven ventilating fans. These are nearly always running, being of neat appearance, and needing very little attention. The repairing tools on board, such as lathes, boring machines, etc., are likewise motor-driven, besides which the generating plant supplies current for the searchlights, shiplighting, and various signalling apparatus, etc.—in fact, it may be said that elec-

Digitized by Google

tricity is utilised on board the "Aegir" for almost every purpose which admits of its application.

Valuable experience has been gained from the electrical installation on board the "Aegir," and this has not been lost on the powers that be. For instance, anchor windlasses are no longer provided with electrical means of driving in the German navy, steam having proved more suited to this particular purpose, since the motors when loosening the anchors from the ground absorbed so much energy that a single primary generator was unable to furnish the requisite current, and parallel running did not seem advisable on account of the involved danger of reversing the poles of the compound-wound machines. The experience gained on the "Aegir" has also proved of service in other directions.

One consequence of the increased use found for electrical energy has been that the pressure of the primary current generated has increased. Formerly when searchlights were responsible for the bulk of the energy consumed, the generators were wound to give 65 volts terminal pressure. On the newer ships of the line in the German navy a pressure of 75 volts is generated, while upon the newer cruisers a uniform pressure of 110 volts has been adopted.

The battleships of the "Kaiser" class now building are to be provided with generating plant consisting of four shunt-wound machines of 60 kw. output each. The interior lighting of each of these ships will require from 35 kw. to 40 kw., while the five searchlights with which each is equipped will absorb another 45 kw. to 50 kw. What energy remains for disposal is to be utilised for driving ventilating fans, ammunition hoists, gun turrets, and coal hoists, etc. Besides the primary generators, the ships of the above-mentioned class are to be provided with accumulators for supplying current to certain of the ship's apparatus. The batteries will be worked in parallel with the primary generators if required, to which they act as a reserve, being of sufficient capacity to supply the signal lamps and ship's lights for a long time in case the main source of supply should fail. In part the new ships will be provided each with three batteries of accumulators, of which one will remain in parallel with the primary generators for service at a moment's notice in case of necessity, while the other two will supply at a lower pressure (35 volts) to the ship's telegraphs, etc. One of the latter batteries will be charged as the other is discharged.

I have by no means exhausted the source of information already mentioned, but the above notes should give some idea of the extent to which electricity is usefully applied in the German navy. That attention should be drawn to the matter is all the more necessary having regard to the obsolete methods of hoisting ammunition, etc., still prevailing in our own navy, upon the protection of which our very existence as a nation is admitted to depend. Individual instances of good progress in this direction may be pointed to, but, as a whole, our navy is woefully behind the times in matters of detail and consequent moment. In the course of an excellent series of articles describing the manœuvres recently completed from the vantage point of one of our more modern cruisers, Mr. H. W. Wilson asks some very pertinent questions in the *Daily Mail*. Speaking of "shell hoists," he says: "The bugle's fierce note is heard, caught up and re-echoed by other bugles in other parts of the ship. Then follows the snapping and clicking of breech-blocks opening and shutting, and all the elaborate mimicry of a furious battle. But if this were the 'real thing,' would not these two forecastle guns before us be hard put to it to keep up the supply of ammunition? The 100lb. shells, the heavy brass cartridge cases, with their 13lb. of cordite, have to be hoisted by four men a height of 42ft. from the magazine in the sweltering bowels of the ship below to the cool daylight of the upper deck. Other navies harness electricity or hydraulics to do such work; our fleet will have none of these agents, alleging their liability to breakdown. Years ago I saw in French and Italian cruisers projectiles and charges whipped up by the half-dozen by such instrumentality. Is there not risk in our fleet—even in our best and newest ships—of our fire being too slow? And in speaking thus, I am only reflecting the sentiments of certain officers on board." Further comment is needless.

(To be continued.)

LOSSES IN SMALL LIGHTING PLANTS.*

BY B. V. SWENSON AND A. W. RICHTER.

The history of the development of electric lighting shows that the splendid advancement which has been made in the economical production of electric current is due largely to careful and scientific tests of electric plants and apparatus which have been made from time to time.

The complete commercial test when properly planned and executed will demonstrate the exact conditions under which a plant is operating, showing the losses which occur in the various parts of the system. By a proper interpretation of the test all losses may be located, and means may then be devised for improving the efficiency of the plant. The report of such a test should be arranged in a simple, straightforward manner, and should contain all essential data. A brief description of the test should be given, and the results and conclusions should be plainly and logically set forth.

Large plants have been tested more frequently than smaller ones, but in a general way these tests have also been of advantage to the smaller plants, as they have shown where machinery and other apparatus were faulty or uneconomical, the result being that manufacturers have improved their product very materially.

In consequence of this, some of the apparatus, as, for example, the steam-engine, has been so perfected that but little improvement in its efficiency is possible. Again, various station appliances, both mechanical and electrical, have been devised for increasing the station output and efficiency.

When such tests have been made, they have usually brought forth excellent results. Small lighting plants, however, have suffered in this particular, the reason being largely the lack of a full appreciation of the value of such tests. Then, too, it very often happens that the management realises that improvements might be made and yet is not aware of the fact that, by means of a scientific investigation of a thoroughly practical nature, one can determine just where improvements can best be made.

In a large number of cases, small plants, as well as large ones, would be greatly benefited by a practical test, if properly conducted and interpreted. This is especially true of some of the earlier plants, containing machinery and apparatus which, although the very best at the time of installation, is now almost or entirely out of date.

Very frequently in a case of this kind a test will demonstrate that it would be a good investment to "scrap" certain apparatus and to replace with new and more modern equipment. Indeed, it many times occurs that the saving made in one or two years will more than pay the cost of making the change.

It must not be understood in this connection that the writers are condemning old apparatus in general and advocating its replacement with new equipment in all cases. Far from it, for it very frequently occurs that apparatus which has been installed for a number of years will, with certain changes, still serve economically and well. Instances have come to the attention of the writers in which entire new equipment has been advocated, but where, by a proper remodelling of the plant, probably replacing some equipment with new and rearranging the plant in general, it may be operated practically as economically as with new equipment, and with far less expenditure of capital.

In order to illustrate the importance of what has been said, the results are given of one of the tests recently made by the writers in this immediate vicinity.

The plant in question is a combined lighting and pumping station. The boiler-room contains two return tubular boilers, each of 43-h.p. capacity. The feed water was taken from the main and passed through an open exhaust heater before entering the boilers. The engine-room contains a 125-h.p. Ideal engine, directly belted to a 90-kw. 2,200-volt Westinghouse alternator. The switchboard is arranged to control two single-phase feeders, each of 45 kw. capacity. The pump-house contains two duplex Deane

* Paper read before the North-Western Electrical Association at Waupaca, Wis., June 27, 1900, and reproduced in the *Western Electrician*.

Digitized by Google

pumps, each of which (at the ordinary speed of operation) has a capacity of 400,000 gallons in 24 hours.

Time will not permit of a detailed description of such a test, neither does it come within the scope of this paper, but a few of the general results obtained may be of interest. The object of the test was to determine the efficiencies of the plant and all parts thereof under actual operating conditions, and to decide upon what changes, if any, were advisable.

The coal was weighed as it was brought into the boiler-house; the water was pumped into two weighing tanks, so arranged that one could be filled while the other was being emptied. Calorimeter tests at boilers and engine were taken every hour; all other boiler-room readings were taken at half-hour intervals. Indicator cards at the engine and all engine and switchboard readings were taken every 10 minutes. In the pump house all readings were taken at 15-minute intervals.

The station was operated under ordinary working conditions. Boiler No. 1 was started at 2.15 p.m., and at 3.15 p.m. one of the city pumps was started. Boiler No. 2 was fired up at 4.5 p.m., and the city pump was stopped at 5.31 p.m., after which there was an entire stoppage until five minutes of six, when the lighting engine and alternator were started. The arc circuit was thrown on at 7.28 p.m. and stopped at 12 midnight. The whole plant was shut down at 1.15 a.m.

All instruments used were carefully calibrated in the laboratories of the University of Wisconsin, both before and after the test. The data were taken by the writers, with the assistance of two students of the university, and entirely independent of the station employés. Some of the results of the test follow:

Steam pressure, pounds	72·2
Draught gauge, inches of water	0·375
Escaping gas, degrees Fahrenheit	407
Feed water, degrees Fahrenheit	136
Kind of coal	Indiana block
Total coal consumed, pounds	3,394
Dry coal consumed, pounds	3,275
Refuse, pounds	390
Refuse, per cent.	11·5
Flue gases—Carbon dioxide, per cent.	6·57
Oxygen, per cent.	13·43
Quality of steam, per cent.	98·5
Total weight of water used, pounds	19,242
Total water evaporated, dry steam, pounds	18,950
Evaporation per pound of fuel, actual pounds	5·79
Evaporation same from and at 212deg. F.	6·45
Evaporation same of combustible, actual, pounds	6·57
Evaporation from and at 212deg. F. per pound of combustible, pounds	7·32
Evaporation per square foot of heating surface per hour, actual, pounds	1·44
Evaporation per square foot heating surface per hour from and at 212deg. F.	1 61
Standard commercial horse-power	56·55
Builder's rating at 15 square feet of heating surface (two boilers)	80 60
Ratio of commercial to builder's rating, per cent.	70·2
Time of engine and alternator trial, 5.50 p.m. to 1.10 a.m.	
Duration of engine and alternator test, hours	7·33
Water pumped into boilers, pounds	16,254
Water drawn from separator at engine, pounds	370
Dry steam charged to engine, after deducting that used by calorimeter, separator, and auxiliary pump, pounds	15 323
Dry steam charged to plant, after deducting that used by calorimeters and auxiliary pump, pounds	15,683
Coal charged to plant, 5.50 p.m. to 1.10 a.m., pounds	2,681
Average indicated horse-power of engine	62·3
Maximum indicated horse-power of engine (8.40 p.m.)	93·2
Total watt-hours	179 350
Average electrical horse-power	33 2
Maximum electrical horse-power	56·2
Load factor (average electrical horse-power ÷ maximum electrical horse-power) per cent.	39
Water pumped into boiler per engine, indicated horse-power hour, pounds	31 2
Dry steam per engine indicated horse-power hour, pounds	33 5
Dry steam per plant indicated horse-power hour, pounds	34·3
Coal per engine indicated horse-power hour, pounds	5·37
Watt-hours per pound of coal	66·9
Friction of engine, alternator excited, and exciter, horse-power	21·2
Friction of engine, per cent. of total load	8
Average efficiency (electrical horse-power ÷ indicated horse-power), per cent.	53 2
Maximum efficiency (electrical horse power ÷ indicated horse-power), per cent.	62·8

Duty of city pump:

Per pump displacement per 1,000,000 B.T.U., foot-pounds	13,810,000
Per tank displacement per 1,000,000 B.T.U., foot-pounds	12,780,000
Per pump displacement per 1,000lb. dry steam, foot-pounds	13,940,000
Per tank displacement per 1,000lb. dry steam, foot-pounds	12,900,000

The management was under the impression that the boilers and heater were not of sufficient capacity, and that it would be necessary to purchase a larger boiler and heater, which would entail a considerable investment of capital. The test shows that the boilers are operated at an average of but 70 per cent. of their rated capacity, and during the two hours of heaviest load they operate at but 5 per cent. above rated capacity. It will be seen, therefore, that the boilers are of sufficient capacity for the present requirements of the plant. The temperature of the feed water (Fig. 1),

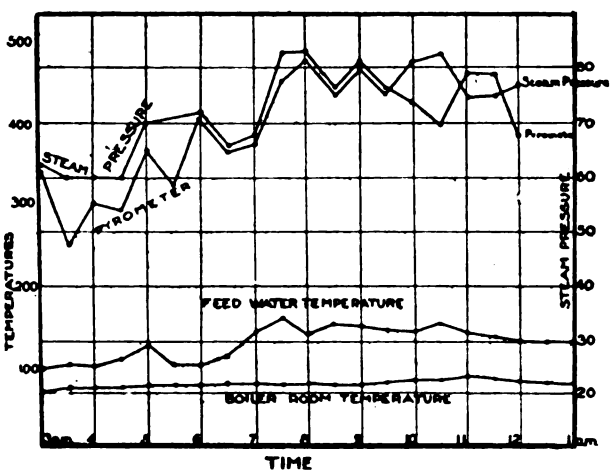

FIG. 1.—Boiler-Room Readings.

as given in the test (133deg. F.), is lower than that of the water as ordinarily pumped into the boilers. This result is due to cooling, while the water was pumped into the barrels and from there into the boilers. In order to find the actual temperature at the time when no test was being made, the temperature of the feed water was taken on the evening following the test. The data obtained showed an average temperature of 204deg. F. and a temperature of 208deg. F. at the time of maximum load (7.30 to 10 p.m.). This temperature is as high as can be obtained by the use of an exhaust heater without increasing the back pressure on the engine. A higher temperature would be conclusive proof that the back pressure is excessive, and is therefore undesirable.

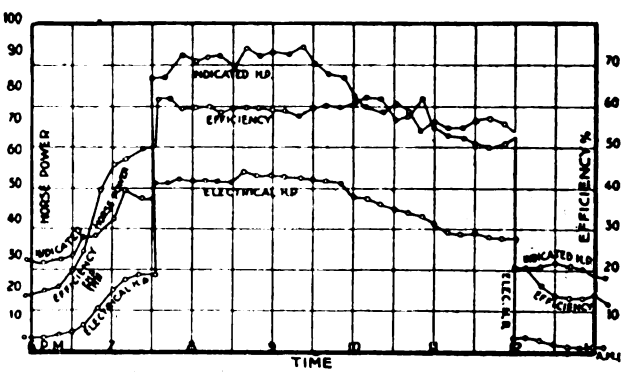

FIG 2.—Engine and Alternator Load Curves.

The indicator cards show that in all cases the pressure drops to atmospheric pressure immediately after opening the exhaust, and gradually rises until compression begins, reaching about 3 8lb. during the time of heaviest load, and 2 5lb. during the time of light load. This rise is caused principally by the piping, and cannot well be avoided when both engine and pump exhaust into the same heater. The average back pressure of the engine—namely, 1·9lb. for the period of heavy load and 1 2lb. for the period of light load—is very good. The back pressure on the pump, while it was in operation, was less than 2lb. The heater is therefore of sufficient capacity for the present needs of the plant, as shown by the test.

Digitized by Google

The evaporation (pounds of water per pound of combustible from and at 212deg. F.)—namely, 7·32lb.—is fairly good, considering the conditions and the method of handling the plant.

The flue-gas analysis shows an average of 6·57 per cent. of carbon dioxide. This result is too low, and shows that too much air is admitted to the furnace. It was found that during the time of light load and after starting boiler No. 2, a test of the flue gases showed but 2·3 per cent. of carbon dioxide, while during the time of heavy load (8.15 to 10.15 p.m.) there was about 8 per cent. of carbon dioxide. This last result is fairly good, although it can be improved upon. With very careful handling of the dampers and fire an average result of from 8 to 10 per cent. can easily be obtained.

The steam-pipe from boilers to engine was not covered. The test shows that during 7½ hours 407lb. of steam (equal to 2·54 per cent. of the total amount) was lost between boilers and engine. This loss was due in part to radiation, and partly to steam escaping with the water in the separator, due to the fact that the drain from the separator was not

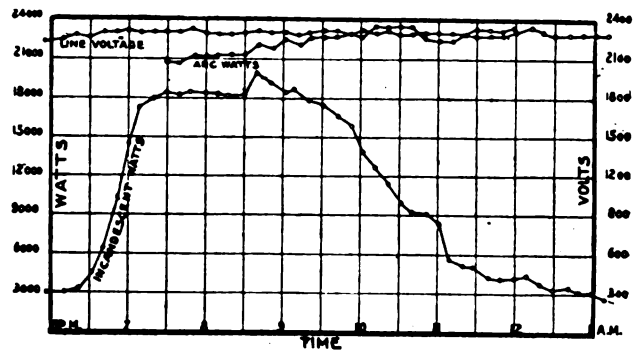

FIG. 3.—Line Load Curves.

kept entirely closed. Assuming a radiation of one British thermal unit per square foot of radiating surface per degree per hour, 1 per cent. is accounted for, leaving 1·54 per cent. to be charged to the separator.

The engine and alternator are both of very recent design, and, if they were operated at anywhere near full load, would leave little to be desired in this direction. Load and efficiency curves of engine and alternator are shown in Fig. 2. Electrical and indicated horse-power data are given as vertical distances, and time as horizontal distances. It will thus be seen that the electrical and indicated horse-power can at once be read off for any time of the day.

The average electrical horse-power is but 33·2, while the average indicated horse-power is 62·3. The maximum elec-

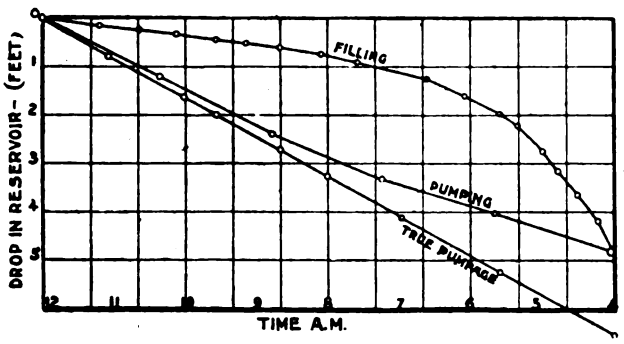

FIG. 4.—Water Curves.

trical horse-power is only 56·2, and the maximum indicated horse-power is 93·2. The minimum electrical and indicated horse-power are 3·6 and 24·8 respectively. These figures show to how great an extent the unit is underloaded. The low efficiency, which is due to this cause, averages 53·2 per cent., reaching a maximum of 62·8 per cent. at 10.10 p.m., and having a minimum value of about 14 per cent. This means that on the average 53·2 per cent. of the power generated in the engine cylinder reaches the switchboard; the remainder, 46·8 per cent., is lost in the transmission. When the lighting unit is in operation all night, this loss is increased to a considerable extent.

An investigation was made of the saving, if any, that might be made by the addition of a smaller unit, which might be operated during the period of light load and when the arc lights are not in use. It was found that with a run to 1 a.m. the investment would bear a good percentage of interest.

The horse-power and efficiency curves show the very light load on the electric station during the earlier hours of the evening and after the arcs are taken off at night, the efficiency of the unit falling as low as 13 per cent. It is evident that a smaller unit, if installed, will decrease the cost of operation to a considerable extent, besides furnishing a duplicate outfit. In case of accident to one of the units, the station will still be able to furnish light to its patrons.

A 30-kw. unit will be able to operate the incandescent circuit during the entire run, and it is therefore advisable to instal a unit of this size. The average electrical horse-power for the incandescent circuit during the entire run is 14·6 e.h.p., and the maximum is 26·8 e.h.p.

The results of the test show that the changes contemplated before the test was made are not necessary at present, but that other changes might be made which would greatly improve the economical operation of the plant.

[The paper was read by Prof. Swenson, who, at its conclusion, explained the diagrams (Fig. 3, showing the line load curves, and Fig. 4 the pumping tests) in somewhat greater detail. The graphical demonstration of heat losses in furnace, boiler, auxiliaries, engine, and dynamo, here

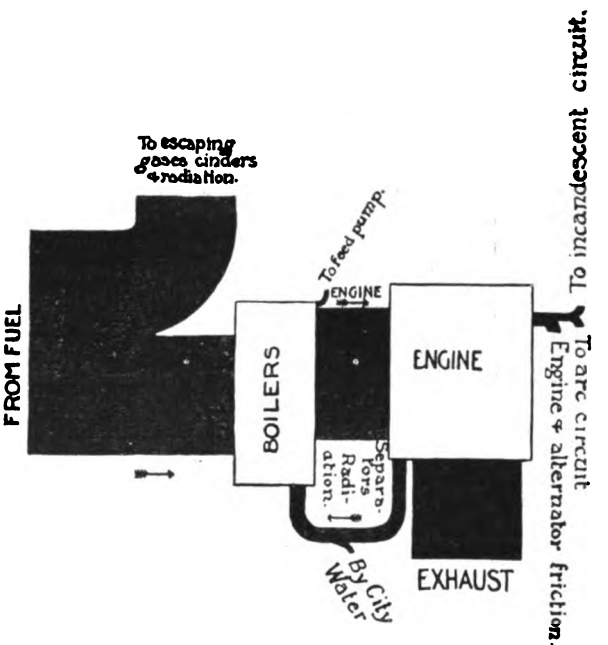

FIG. 5.—Diagram showing Losses in Heat Energy from Fuel to Switchboard.

denominated Fig. 5, was viewed with especial interest by those present.]

CONDUIT v. TROLLEY.

The following appeared in the *Daily Mail* of Wednesday, Aug. 8:

Against the Costly Conduit.

THE CASE FOR THE TROLLEY TRAM IN LONDON.

BY J. CLIFTON ROBINSON, C.E., MANAGING DIRECTOR AND ENGINEER TO THE LONDON UNITED TRAMWAYS COMPANY, LIMITED.

The adoption of the conduit system on electric tramways is a mistake which, if persisted in, will, in my opinion, entail loss on the working, and will delay, by its costliness of construction, the development of rapid transit in London. The conduit system will be found practically impossible in many of the central parts, while its cost will be at the least double that of the trolley, and it is naturally liable to more frequent interruption both from physical and climatic causes.

In proposing to adopt the conduit, the London County Council is, in fact, going contrary to the consensus of opinion

Digitized by Google

on electric tramways throughout the world. The trolley has proved itself to be the simpler and cheaper of construction, easier in maintenance, and more economical in working cost from day to day, than any other method yet known. With an extended personal experience embracing nearly the whole of Europe, North America, and Canada, and after a most careful enquiry into all known inventions and proposals, I am firmly convinced that, for many reasons, the electric trolley system is to-day the best method of tramway traction which any community can adopt.

The Conduit's Sole Advantage.

The only advantage possessed or that can be claimed for the conduit over the trolley is that it does away with the overhead wires necessary in the trolley system. These wires have been talked about and written about until to some they have become bogeys. In actual use they present no inconvenience, and their alleged unsightliness is a mere exaggeration. There is no danger with them, for if they from any cause accidentally break, the current is at once automatically cut off. Those who wish to judge of their outward appearance should satisfy themselves by inspecting the installation now being made along the streets of the western suburbs by the London United Tramways system. The conduit, as above hinted, has inherent faults which help to prove its impossibility for London. It is, besides, very costly. A well-equipped trolley line ought not to cost more than £20,000 per mile of double track, while the construction of a conduit system would at least run into double that amount for the known quantities of the work; while for the unknown factors, which must arise in many parts of central London, it is impossible to estimate the outlay further than to say that it must be gigantic. In proof of this let me briefly describe the construction of the conduit system.

How the Conduit is Built.

It requires a continuous chamber to be made below the surface of the street, going down, with its concrete foundations, to from 4ft. to 6ft., and strong enough to bear any weight, up to a traction engine, that can be brought upon it. This subway, or "conduit," must be open to the street by a continuous slot, from ¾in. to 1½in. wide, through which the plough of the car goes, to pick up current from an insulated yet open electric conductor. The construction and maintenance of such a conduit would present insuperable difficulties in London, for there, immediately below the roadway, is found a maze of pipes of every kind, including sewers, gas-pipes, water-mains, and many others. The most experienced surveyors and engineers cannot tell without excavation where many of these pipes are, for after long years all trace of them has been lost. They bend and twist, and intersect and bisect the streets in a way almost impossible to believe.

If the conduit system were adopted, the whole of these pipes within 3ft. or 4ft. of the surface of the roadway would have to be taken up, diverted, and relaid. The cost of doing this, in the oldest streets, might well run into many thousands of pounds, while in many parts it would be almost impracticable for the most experienced to estimate the cost.

What about Gas and Water Mains?

A further practical difficulty, of course, is that the County Council would not be permitted to move gas or water mains. It would first have to open up the street to find where the pipes where, and then it would have to wait the convenience of the gas or water company, which would do the work when it was most convenient to them, and then send the bill of costs (over which there would be little or no control). As an example of this, I may state that, in altering the elevation of a bridge at Hounslow, the London United Tramways found it necessary to lower some water-mains. The water company kept us waiting months before it did the work—and we could do nothing but wait.

This brings me to the next point. The placing of a trolley line involves no more disturbance of the streets than the ordinary relaying of part of a roadway. One-half of the line is done at a time, and the street otherwise remains open for traffic. But in the building of a conduit, streets must be entirely closed to vehicular traffic for probably months at a time, and to many tradesmen along the streets through which the conduit line is run this would mean dislocation of business, and to everyone much loss and inconvenience.

What are the Advantages?

The great practical question remains. After the conduit has been built, after the tremendous cost has been met, and the engineering problems have been effectually overcome, would it present any advantage over the trolley? Would it work better or cheaper? Experience goes to show that it would not work nearly so well. The conduit, with its open slot, practically acts as an open sewer. All filth, all rubbish, drift into it. It presents greater dangers for electrolysing gas and water mains than does the trolley, for with every fall of rain the current is dissipated all around. When floods of water come down the roads in the rainy weather peculiar to this climate, as in some of the hilly parts of northern London, the conduit will for the time be stopped. There is, further, an actual personal danger, for the slot would present a constant temptation to children or mischievous persons to choke it up with anything they could pass down the slot; or, ignorant of their power, to try to obtain "shocks" by reaching down to the naked electric conductor with wires or metal rods.

Conduits Abandoned Elsewhere.

The objections to the conduit are—they seem to be theoretical, but not practical. In establishing electric tramways, London is only following the lead of many other cities. Some cities began by trying the electric conduit, but only to abandon it, in nearly every case, for the overhead trolley. New York City is often quoted by advocates of the conduit as a case in their favour; but to quote New York as an example for London is absurd, for the conditions of the two cities differ so largely that there can be no comparison. When conduit lines began recently to be established in New York, there were already in existence underground tracks built for the cable lines which could be readily adapted. Conduits are, further, easy to build in New York, because there does not exist the same maze of unknown zigzag mains to deal with which are to be found in London.

When the London United Tramways Company wished to introduce electric traction on its line in West London, the London County Council used all its influence to induce us to establish the conduit on at least those sections of our system within London. But rather than listen to the voice of the charmer, we waited for two years or more till we at last secured powers to use the trolley line over all our routes.

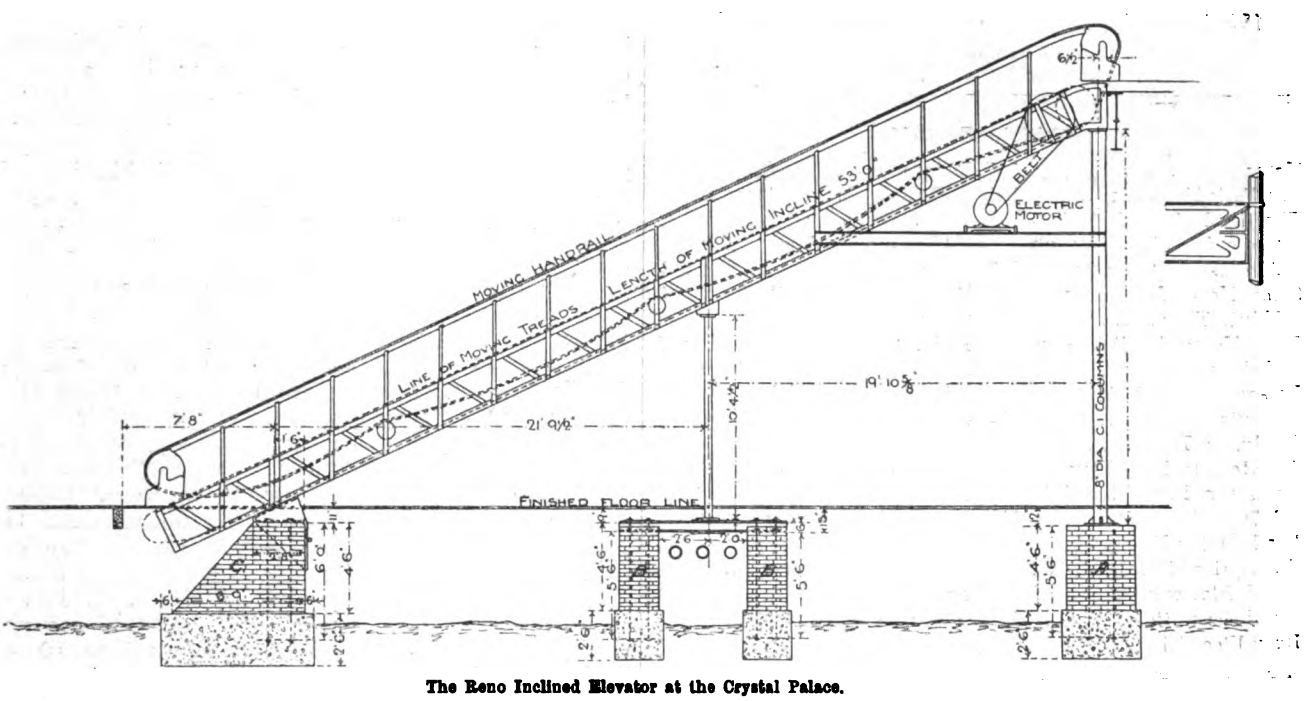
Our approaching electric inauguration, which will take place this autumn, will at once, I believe, shatter the prejudices of many who had objected to the trolley. For the trolley, wherever it has been established, has been a complete success, and has converted its most determined foes into its greatest advocates.

THE RENO INCLINED ELEVATOR.

The introduction of yet another American innovation into this country was celebrated on Friday last, when a number of Pressmen and others visited the Crystal Palace for the purpose of seeing the elevator installed there by the Reno Inclined Elevator Construction Syndicate, of 70, Finsbury-pavement, London, E.C., in operation. It is the first elevator of its kind erected in this country, though, we understand, already extensively adopted in the States, not to mention the Paris Exhibition and elsewhere. The accompanying illustrations will enable the construction of the elevator to be readily understood. When intended for single-file service, the elevator is given a width of 3½ft., for double service 5ft., and is built at an angle of 25deg., as shown. The structure consists of steel framework, bolted at the top to the steel floor beam or header, and similarly supported at the bottom. Near the middle it is supported by a steel column, the weight at that point being about 2,100lb. The moving incline consists of a series of hardwood slats or treads of a special form, attached to an endless chain, rotated by a sprocket wheel. These slats have fastened to them a series of rubber-covered longitudinal ridges, each being ¾in. wide and 1in. high. They serve as a comfortable footing for the passengers. To ensure a perfectly smooth and safe landing at the upper end of the machine, the feet of the passenger, which rest upon these rubber-covered ridges, are slid off as they arrive upon a comb shaped landing consisting of cast-iron prongs, which

Digitized by Google

fit into the grooves separating the ridges. To each end of the wooden slats is attached a small anti-friction wheel made of hemacite. These roll upon angle-iron tracks on both their upward and downward passages, and insure easy and noiseless running. The endless tread chain, besides passing over the sprocket wheel at the upper end of the machine, also passes over an idler sprocket wheel at the lower end. Attached to the shaft of the upper wheel is a reduction gearing directly connected with the electric



The Reno Inclined Elevator at the Crystal Palace.

motor. The speed of the motor, 550 revolutions per minute, is thus reduced to about 14 revolutions per minute at the driving sprocket, which gives the moving incline a speed of 90ft. per minute.

In order to steady the passenger in his ascent on the machine a moving handrail is provided. This consists of an endless steel chain of special construction, which slides in a groove in a steel bar running from one end of the machine to the other, the upper and lower ends of the chain passing around sprocket wheels enclosed in ornamental

step on to the inclined surface, when they are carried easily and comfortably—at the Crystal Palace—from the ground level to the gallery above, a height of 21ft. 7½in., the over-all length of the elevator being 51ft. In this manner the elevator is capable of dealing with 3,000 passengers per hour, its capacity being equal, it is claimed, to that of six vertical lifts. When fully loaded the elevator requires about 6·4 h.p. to drive it at its normal speed, and when empty 1·4 h.p. This power is furnished by an electric motor coupled as shown in one of the accompanying illustrations. The short drive from the motor to the main shaft was necessitated in this case by special conditions. The elevator is designed to obviate the disadvantages of the vertical type of elevator. Its greater relative capacity is sufficiently obvious, and the advantages of having an elevator constantly at work during business hours, and, moreover, available at any moment without wait or bother, give the new elevator a wide field of applicability and usefulness. It is claimed, amongst

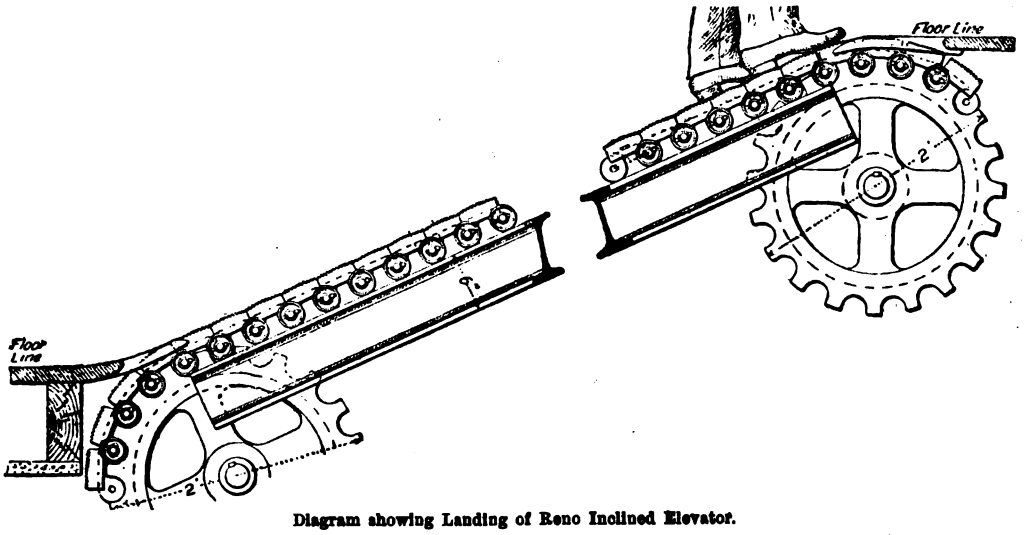


Diagram showing Landing of Reno Inclined Elevator.

iron casings. The chain, after passing around these sprocket wheels, also passes over a third sprocket wheel on the main shaft of the machine, which thus drives the handrail the same rate of speed as the moving platform. The handrail chain is covered by flexible rubber covering, which presents a comfortable surface for passengers to grasp. Needless to say, this chain handrail is another special feature of the machine. It is built up of cast-steel interchangeable links, so that it may be easily tightened up if necessary. The elevator is intended to run continuously, passengers having simply to

many other advantages, that the elevator makes the second floor or basement of store buildings almost as accessible to the public as the ground floor. Its adaptability as a freight elevator for steamships, docks, warehouses, and factories is also pointed out. Places of entertainment like the Crystal Palace, for instance, should benefit by its introduction on account of its novelty. As to actual results in this direction it may be mentioned, in conclusion, that the Reno inclined elevator at the Crystal Palace on Bank Holiday took up over 10,000 passengers at a charge of 1d. per head without hitch.

FROM THE INTERNATIONAL IN 1878 TO THAT IN 1900.

Twenty-two years ago Paris was engaged, as now, with an international exhibition. Then Gramme, Jablochkoff, Planté, and one or two others made that leap in electrical practice which has since given rise to the dominant industry of the world. Till then various men had laboured and experimented, but the results of the labours and experiments had not taken the world by storm; but the time had come, and since that exhibition there has been no going back. Even with the glamour of the 1878 exhibition upon us but few believed in the possibilities of electric light as an artificial illuminant. If any reader cares to do so, let him turn up the *Journal of Science* for February, 1879, and he will find therein two or three very suggestive papers. In one, Mr. W. Mattieu Williams details his experience from 1845 onward with investigations into the applications of electricity. His conclusions are emphatically stated. He says: "During the intervening thirty years I have abstained from further meddling with the electric light, because all that I had seen then and have heard of since has convinced me that, although as a scientific achievement the electric light is a splendid success, its practical application to all purposes where cost is a matter of serious consideration is a complete and hopeless failure, and must of necessity continue to be so." What danger there is in prophesying unless you know, and how often during the past twenty years must Mr. Mattieu Williams have wished those words unsaid. Had the conclusions been different, it is possible we should not have had to wait till this year of grace to know how near Mr. Staite and his colleagues were to the solution of the problem, not only as regards the lamp, but also the dynamo. It was Gramme's work in the latter direction that made progress possible and rapid. Williams refers to Staite's attempt to obtain a lamp by means of a carbon rod in a Torricellian vacuum, and Prof. Ayrton in the same number describes his work upon such a lamp as long back as 1873, though after obtaining a vacuum he filled his globe with nitrogen. The third paper we have referred to is one by Profs. Elihu Thomson and E. J. Houston, showing that size, weight, and cost of the copper conductor required for transmitting power over a distance of 500 miles or more were not, as some writers at that time insisted, prohibitive in either of these directions. It was in April, 1879, that the late Dr. Hopkinson read his first classic paper at the Mechanical Engineers, and started the scientific process of the construction of electrical engineering apparatus. How vast the work done in all directions between the years 1878 and 1881 can be understood by referring to the reports of the electrical exhibition held in Paris in 1881.

The avidity with which electric lighting was taken up in other countries, and especially in America, where the prevailing conditions were altogether in its favour, led to legislative action in this country, and gave us the justly celebrated 1882 Bill. The

Digitized by Google

passing of this Bill led to the following remarks by Sir F. Bramwell: "The passing of this Bill must be looked upon as the beginning of the end of the carrying out of public enterprises by means of private capital." He also correctly prophesied stagnation while the inequitable conditions of the Bill remained. As we all know, these conditions had to be modified by a subsequent Act, and then came a period of activity. It is well to occasionally remember the facts of rise and progress. In our last issue we pointed out how useful American energy had been to the industry, and the moral of our present remarks may be taken to indicate that France has by her exhibitions at critical times made the world acquainted with the position of electrical matters, and by these "bold advertisements" has conduced largely, if not entirely, to epoch-making. If the Britishers have not taken kindly to Paris this year, it is not that they deprecate the value of the interchange of opinions or the examination of differences in practice, but from other and varied causes which it is needless to elaborate. The facts remain as we have stated, that the electrical industry owes much to exhibitions in Paris.

FORTHCOMING EVENTS.

SUNDAY, AUG. 12.

Institution of Electrical Engineers.—American Institute's visit. Trip up the Thames in launches.

MONDAY, AUG. 13.

Institution of Electrical Engineers.—American visit. Dinner at Prince's Restaurant, Piccadilly, at 7 p.m. Also, during the day, visits to Board of Trade Laboratories, Telegraph Department of G.P.O., Central London Railway, and Westminster Electric Lighting Station.

Institute of Junior Engineers.—Summer meeting at Newcastle-upon-Tyne. Reception at Town Hall by the Mayor. Visit Messrs. Swan and Hunter's and the Electric Supply Company's works.

TUESDAY, AUG. 14.

Institution of Electrical Engineers.—Visits to School of Military Engineering and Royal Dockyard, Chatham. Lunch at Royal Engineers' Mess Reception by Lady Fraser in the afternoon.

Institution of Junior Engineers.—Visit Messrs. Armstrong, Whitworth, and Co.'s Elswick Works, the Engineering Department of Durham College of Science, and the Newcastle and District Electric Lighting Company's works.

WEDNESDAY, AUG. 15.

Institution of Junior Engineers.—Trip on the river to inspect the Tyne Improvement Commissioners' works.

THURSDAY, AUG. 16.

Institution of Electrical Engineers.—First day of joint meeting of English and American Institutions in Paris. Subject for discussion, "The Relative Advantages of Alternate and Continuous Current for a General Supply of Electricity."

Institution of Junior Engineers.—Excursion to Sunderland to inspect the works of the River Wear Commission.

FRIDAY, AUG. 17.

Institution of Electrical Engineers.—Paris meeting, second day.

Institution of Junior Engineers.—Visit the Allhusen Works of the United Alkali Company, the preliminary works of Corporation electric tramways. Summer dinner at County Hotel.

SATURDAY, AUG. 18.

Battersea Vestry.—At 3.30 p.m., foundation-stone laying of Lombard-road central electric station.

International Congress of Electricians at Paris.—Aug. 18-25.

WEDNESDAY, AUG. 22.

Institution of Electrical Engineers.—Paris meeting; reception in the British Royal Pavilion in the Paris Exhibition, 5 to 7 p.m.

WEDNESDAY, SEPT. 5.

British Association.—Annual meeting at Bradford.

Paris.—The Association des Industriels de France contre les Accidents du Travail offer a prize of £40 for the best insulating gloves for the use of those employed in electric works. Particulars must be supplied by Dec. 31.

DESCRIPTION OF THE BLACKPOOL AND FLEETWOOD TRAMROAD AND GENERATING STATION.*

BY TOM G. LUMB, A.M.I.C.E.

The Blackpool and Fleetwood electric tramroad constitutes one of the most popular amusements we have in our midst to-day. It opens out a part of the Fylde possessing charms and beauties absolutely unknown to the great majority of the vast crowds of holiday makers. The ride on a smoothly-running electric car over the cliffs at North Shore and Bispham through the famous "Wilds of Norbreck," and thence to Rossall and Fleetwood, adds a new joy to the delights of a holiday at Blackpool. For several miles the line skirts the edge of the coast, and passengers have the advantage of a magnificent uninterrupted view of the sea on the one side and the verdant meadows and pastures on the other as far east as Bleasdale Moors. Judging by the number of passengers this season, the novelty and attractions of the ride strongly appeal to the holiday makers. Persons having business to transact in Fleetwood, or any of the intervening villages, find the cars a great convenience. Numbers of private residences are being erected along the route. The line, over 8½ miles in length, double track, was laid in a few months, and speaks well for the smartness and efficiency of the staff of the contractors, Messrs. Dick, Kerr, and Co. It is one of the best paying tramroads, if not the best, in the world. One could hardly grasp the fact that in the first 12 weeks no less than 550,000 passengers were conveyed, thus realising over £12,000, and this with only 10 open cars running.

The line commences opposite Talbot-road railway station, and passes along Dickson and Warbreck roads to the Gynn (single line with numerous passing places). From Derby-road to the Gynn there is a "double single" line—that is, the cars go up and down the road on the left-hand side, thus having a double track, but the distance between the tracks is not sufficient for cars to pass. The line then passes through the deep cutting made out of the top of the cliffs to Uncle Tom's Cabin, which was Blackpool's first place of amusement. At Uncle Tom's the ordinary form of tramway construction gives place to a light railway type of construction. Just before crossing the borough boundary of Blackpool there is the commencement of an incline with a gradient of 1 in 42, which brings the tramroad to 95ft. above the level of the sea, this being its greatest height. After leaving Uncle Tom's Cabin we come to the road leading to Bispham and the commencement of the Norbreck Estate, which is being laid out for building purposes, and upon which there are already several private residences erected. Up to Norbreck the line runs along the edge of the cliffs; then it takes a turn inland into the heart of Cleveleys, crossing the main road and running parallel with it to Rossall. Passing Rossall College the line turns to the north-east, and runs with easy curves direct to West-street, Fleetwood, passing the second accumulator station and car-shed just before reaching the town and cutting off the big corner by the hutments. The terminus, as at Blackpool, is near the station and the landing-stage for the Belfast, Douglas, and ferry steamers.

Permanent Way.—The track is of standard gauge and double throughout, except in Blackpool, where passing places are provided. The permanent way includes both tramway and light railway forms of construction. From Talbot-road terminus to the Blackpool borough boundary, and again from Poulton-street, Fleetwood, to the terminus, the line is a tramway. The intervening section—about 6½ miles in length—has, however, all the characteristics of a light railway, the line being fenced and the road being designed for comparatively high speeds. As regards the tramway construction, there are no novel points to note, except that the groove of the rails is made slightly larger to suit the thicker flange required for running on the Vignole rails. The roadway was excavated to a depth of 12in. for the full width of the tracks, and for 18in. on each side of the outside rails. A foundation of 6in. of concrete was then laid down, and on this were laid the girder rails. The rails used in Blackpool

* From the *Transactions* of the Royal Institution of Public Health.

Digitized by Google

weigh 98lb. per yard, and those in Fleetwood 83lb. They are tied to gauge by steel bars at intervals of 9ft. The sets which bring the roadway up to the rail level are of granite. On the tramway sections the electrical connections between the rail ends consists of two copper bonds of the "Daniel" type. On the tramroad the form of construction is entirely different. The route lies across fields, and as the road-bed had to be made throughout it will be readily understood that the work could not be carried out so rapidly as in the case of a tramway. In the latter, materials can be deposited all along the route, and several gangs of men can be simultaneously employed at intervals along the route. There was no roadway beside the route of the tramroad, and ballast, sleepers, rails, etc., had to be carried forward on the rails as the line was prepared, the contractors using small steam-engines for hauling material and for inspection. A large amount of excavation (123,000 cubic yards) was required, the cuttings ranging up to about 16ft. in depth. The great bulk of the material excavated was hard and tough red clay, very difficult to work; in fact, the "gullets" had to be blasted out, as in heavy railway construction. There are six barrel culverts on the line, each 6ft. in diameter, and built of three half-brick rings on a very strong concrete foundation. In building these, close poling and pumping was required (in all except one case), the material met with being "quick" clay and running sand. In some cases the work at the culverts had to be close timbered and finished in lengths of 6ft. or 8ft., the bottom being so bad. There are 10 level crossings on the line, seven of which are on public roads, and all are provided with cattle guards. The track on this section consists of Vignole rails, weighing 56lb. per yard, and laid on transverse sleepers, with centres 3ft. 6¾in. apart. Round all curves, fangbolts, and clips fix the rails in place. The rails are spiked directly to creosoted redwood sleepers (9ft. by 9in. by 4½in.), chairs not being used, and the sleepers are embedded in 12in. of ballast in the usual way. A feature of special interest, since its use is wholly new in this country, is the "plastic rail bond." This bond has been used with what appear to be very successful results in America. It is composed of two portions: a plastic or putty-like metal compound, which makes contact between the rail and the metal of the joint, and a flexible elastic cork case to hold the plastic part in position. In putting the bond in place, contact spots, about 2in. diameter, at the end of both rails and fishplates, rust and scale are cleaned off, and the centre of each of these spaces is rubbed with a special alloy, which changes any iron rust to pure metallic iron, and forms a silver-like deposit, which repels water and will not corrode. One side of the cork case, containing the plastic material and the steel spring, is then placed upon the prepared surface of the web of the rail, and a similar case is attached to the end of the next rail. The fishplate is then bolted down, and, as the bolts are tightened, the cork case is compressed to half its former thickness, and the amalgam in the case comes into full contact with the rail and fishplate, giving an electrical connection between the rails of low resistance. The bond is thus entirely concealed from view, and it is protected by the cork case from injury arising from movement between the rail and the fishplate.

Generating Station.—The generating station and principal car-shed is situated about two miles from the Blackpool terminus and a quarter of a mile from the line, with which the car-shed is connected by a spur track. All the buildings, including a lofty chimney, are constructed of brick. The whole of the installation is compactly and conveniently arranged. The boiler-room measures 68ft. by 66ft., and the engine-room 77ft. by 32ft. The car-shed is 170ft. by 67ft., and is capable of accommodating 24 cars. The Fleetwood car-shed is 116ft. by 67ft., and has accommodation for 18 cars. At the terminus close to the old barracks, known as Euston Barracks, there is a third car-shed, with waiting-rooms, stores, and office. At Bispham, Norbreck, Cleveleys, and Rossall there are waiting-rooms for the convenience of passengers, together with places for stores. Four Lancashire boilers, constructed by Galloways, Limited, of Manchester, form the steam-raising plant. Each boiler is 30ft. long by 8ft. diameter, and the steam pressure is 120lb. Water is obtained from a reservoir adjacent to the engine-room, which is filled by surface water collected from the surrounding fields and springs. It is also provided with one of Klein's patent coolers. If required, water can also be drawn from the local supply, and a storage tank has been constructed above a small outbuilding near the boiler-room. The reservoir, however, is expected to supply all requirements. After passing through the hot-well, the water is fed to the boilers through a set of Green's economisers of 288 tubes. Two direct steam-driven Worthington feed pumps are employed. All steam and exhaust pipes are placed in a basement beneath the engine-room, giving easy access to all parts. The steam-pipes are arranged to form a ring. The main pipe and the branch to each engine are fitted with a steam separator. A water-gauge indicates the amount of water collected, and by means of a valve the attendant may clear the separator of water when required. There are five open marine-type vertical compound engines of 200 h.p. each, running at a speed of 175 revolutions per minute, with cylinders 12in. and 24in. in diameter and 16in. stroke, constructed by Messrs. Mather and Platt. Direct coupled to each engine is a multipolar dynamo capable of giving a continuous output of 120 kw. at 505 volts, to which I shall again allude presently. The engines have cast-iron standards at the back, which, with the polished steel columns in front, serve to support the cylinders and guides for the piston rods. The pistons are supplied with Mather and Platt cylinder rings, packed with metallic packing. The Pickering throttle governor is used, and the engines have hand regulation for the expansion gear. Although the engines usually run condensing, valves are provided so that exhaust may be made direct to the atmosphere. Ledward ejector condensers are used, the condensing water being taken from the storage tank. After leaving the engine-room the water passes down a wooden troughing, and for some distance around the reservoir before entering it. This is used at the times the cooling tower is not needed. The water for the condenser is pumped up by centrifugal pumps driven by Mather and Platt's single-acting enclosed high-speed engines, the pumps being coupled direct upon the same bed-plate. The dynamos, which were constructed by Mather and Platt, have six poles. They have shunt-wound magnets. The yoke casting is in one piece, and the upper half of the machine can be easily removed, this giving access to the armature, which is of the slotted series drum type. The brushes are of the laminated spring type. A noticeable feature in the dynamos is the collar connecting the fields coils and encircling the armature. This arrangement effectually prevents all sparking, and its advantages more than counterbalance the slight loss in electrical efficiency which it entails. As the efficiency of the generators is 93 per cent., it will be seen that the effect of the collars is negligible. The dynamos run with great steadiness, and as the rise in temperature of no part of the machine exceeds 25deg. when working continuously on full load, they run absolutely cool. From the generators the current is conducted to the switchboard, which is fitted with the usual measuring instruments, switches, and automatic circuit breaker of the "Cutler" type, mounted on slate panels, of which there are five, two for the dynamos, two for the feeders, and one for the Board of Trade testing instruments and station switches. Three boosters have been included in the equipment of the station. They stand along the wall beside the switchboard, and occupy little space. These machines consist of a four-pole motor connected direct to a four-pole generator in the same bed-plate. The motor is connected to the switchboard 'bus bars, and the speed may be varied to suit the voltage required by means of a resistance inserted in the shunt windings. The generator side of the booster is capable of developing 130 amperes at 200 volts. By means of suitable switches any feeder may be connected to a booster, by which the pressure at the feeding point is automatically kept constant. This allows all the dynamos to be run in parallel at the same voltage, and all the feeders may be of the same size. By means of the boosters the accumulators may be charged independently of the line. The engine-room is provided with a five-ton travelling crane, which is also designed for use in the adjacent car-shed, which has

Digitized by Google

space and pits for 24 cars. The trolley wires are brought into the shed, so that the cars can be conveniently shunted. At one end of the shed is an 8-h.p. Mather and Platt "Manchester" motor, which drives a shaft for operating tools required for repairs, etc. The whole of the station buildings are lighted by incandescent lamps controlled from one central distribution board.

Distributing System.—Current is conveyed from the generating station to the line by four feeders, each consisting of $^{37}/_{14}$ copper cables, lead-covered and armoured, and laid in trenches along the trolley line. The feeders have an insulation resistance of not less than 1,000 megohms per mile. They are taken into cast-iron section boxes, which are placed at intervals of half a mile along the line, and are then connected with the trolley wire through four wedge switches placed in the section boxes. One feeder cable runs direct to the accumulator station situated near the termini at Fleetwood. At this station there are batteries of 250 cells, made by the Chloride Electrical Storage Syndicate, the battery having a capacity of 300 ampere-hours at a voltage of 500. A small switchboard, fitted with recording voltmeter, for measuring the drop in the rails, and with Aron ampere-hour meters, and watt-hour meters to register the charge and discharge of the cells, is provided at the accumulator station, so that the cells may be connected in parallel with the trolley wire, or the feeder may alone be directly connected to the line, or the cells disconnected from the line and coupled direct to the feeder for charging. Usually the batteries will be in parallel with the trolley wire, as their principal function is to steady the voltage on the line and supply sudden demands for current, thus relieving the generating plant from undue strains. Another important use of the accumulator is to provide power independently of the generating station for early morning or night cars, thus allowing the generators to be shut down over longer periods than would otherwise be the case. The batteries at Bispham and Fleetwood will provide sufficient current for 100 car miles, or six return journeys. This use of batteries for traction, which was first introduced by Messrs. Mather and Platt on the Douglas and Laxey electric tramway, is now frequently employed. Mather and Platt have since made use of batteries on the Snaefell Mountain Railway and the Stockholm and Rimbo Electric Railway, and the system has also been adopted at Leeds and Halifax. In all these installations Chloride cells have been used, with results that appear, so far at least, to be very successful.

Overhead Work—Throughout the line a double trolley wire has been erected, one over each track. The trolley wires, which are ·348in. diameter, are supported on standards, to which the wire is attached by means of brass ears insulated from the pole-arms by Etna insulators. In Blackpool side poles with single arms, fitted with ornamental scroll work, are used, except in a few instances where the width of the road necessitated span wire construction. Along the tramroad and in Fleetwood centre poles with double bracket arms are used. On the poles along the tramroad ornamental scroll work is dispensed with, and the standards are of the simplest character. The trolley wires are divided by section insulators at each section box, so that any section may be cut out if necessary.

Rolling-Stock.—The company have at present in stock 12 open cars, 12 closed cars, and three trail cars; and 12 more cars are in course of construction at the new car works at Preston. Each motorcar is 34ft. 5in. long, and is mounted on two bogie trucks with 28in. wheels. There is seating capacity for 48 passengers, and the car weighs when loaded 12 tons. On each bogie is mounted an iron-clad motor of the G.E. 1,000 type, rated to give about 35 h.p. The motor is geared to the axle through a single-reduction cut gear, enclosed in an oil bath, the ratio of reduction being about 4 to 1. The controllers are of the series-parallel type. As there are no outside seats, the trolley pole is of the ordinary swivel type. The cars are well lighted with incandescent lamps.

The undertaking was initiated by Mr. B. Sykes and Mr. T. S. Turnbull, of Manchester, by whom a syndicate was formed. Dr. Edward Hopkinson, of Messrs. Mather and Platt, and Mr. George Flett, of Messrs. Dick, Kerr, and Co., were prominent members, and obtained an Act of Parliament in 1896 incorporating the Blackpool and Fleetwood Tramroad Company. The portion of the line within the borough of Blackpool was constructed by the Corporation and leased by the tramroad company. The remaining length, from the borough boundary to the Fleetwood terminus, was constructed for the company by Messrs. Dick, Kerr, and Co., Limited, of London. Messrs. Mather and Platt, of Salford, Manchester, carried out the electrical equipment of the power station, overhead work, and the rolling-stock. The whole of the work, excepting the electrical equipment, was carried out under Messrs. Garlick and Sykes, the engineers to the company, with Tom G. Lumb as resident engineer. Mr. H. F. Parshall, of London, was the consulting engineer for the electrical equipment, and Mr. McMahon acted as electrical engineer for the company. The work was commenced about the end of July, 1897, and completed in March, 1898. From July 14 to Dec. 31, 1898, the number of car miles was 173,997. From Jan. 1 to June 30, 1899, the number of car miles was 181,568. The number of passengers carried from July 14 to Dec. 31, 1898, was 734,293; from Jan. 1 to June 30, 1899, was 620,897; and from June 30 to Sept. 9 the number carried was 798,956. The secretary and manager is Mr. John Cameron, who has made a name for himself throughout the tramway world, and the fact of the £10 shares having reached £23. 10s. per share gives one an idea of his capabilities as manager. I have to thank him and Mr. McMahon, the electrical engineer, for their courtesy in supplying me with particulars up to date.

REPORT OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION COMMITTEE ON THE PHOTOMETRIC VALUE OF ARC LAMPS.

This committee, composed of Henry L. Doherty, W. E. Goldsborough, and J. Q. Brown, have presented a progress report at the Chicago meeting of the association. Through the good offices of Purdue University, La Fayette, Ind., the committee has been able to take advantage of the excellent laboratory facilities afforded by the school of electrical engineering in that institution, of which Prof. Goldsborough is the director.

In an accompanying report, Prof. C. P. Matthews, who performed the photometric work, gives a detailed description of the methods and devices perfected by him to minimise the errors and uncertainties arising in arc light photometry. The most unique of these is the adoption of two mirrors instead of one to direct the light from the source to the photometer. These mirrors are placed on opposite sides of the arc, and, as a result, the illumination of the photometer disc is rendered fairly uniform. Thus the fluctuations, so troublesome when measurements are made in the usual way with a single mirror, are greatly reduced. The colour difference is also lessened by the use of a rotating sectored disc of very small angular aperture. This diminishes the apparent illumination of both sides of the photometric field to a point where the colour difference ceases to be troublesome. Another device for lessening the labour of the process, and also the retinal fatigue, is the recording drum. This has been already described, but in these tests it has been used with an electromagnetic recorder, which somewhat enhances its usefulness. To test the efficacy of this combination of devices in eliminating errors peculiar both to the source and to the method, readings were made by a number of observers. These measurements show a very satisfactory agreement, demonstrate that the end sought has been accomplished, and that personal and other errors are not greatly in excess of those met with in the photometry of steady and monochromatic sources.

Reference to Fig. 1 will show the disposition of the apparatus as used in these tests. The two mirrors, M M', are mounted at the extremities of iron arms, and are suitably counterbalanced as shown. The arc is fixed in the centre of rotation at *a*, and light is incident upon the photometer disc at *c*, by the two paths

Digitized by Google

shown in dotted lines, direct light from the arc being cut out by a screen not shown in the figure. This plan necessitates a fixed photometer, P, and in order that a variable illumination may be produced to balance that due to the arc, a cord and windlass are arranged, W, permitting the observer to move with facility the secondary standard, S, which is an incandescent lamp. At D is shown a long wooden cylinder, upon which is wrapped the paper to receive the records of the test. These records are made by an electromagnetic device, R, which punctures the paper whenever an electric circuit is closed at the button, B. The observer, seated before the photometer in a closely-screened enclosure, operating with one hand the windlass, and with the other the push-button, is enabled to take settings with relatively great rapidity and accuracy. At a point 200cm. to the right of the photometer disc a reserve standard is mounted on an arm which may be swung into a position in line with the bar. This reserve standard was carefully evaluated once for all in terms of the Hefner lamp. To determine the intensity of the secondary standard, S, it is only necessary to turn the reserve into position, and record a series of readings in the same way as for the arc. This operation is carried out at the end of each test, or more frequently if any change has been made in the temporary standard. Thus it will be seen that, should the lamp under test be found particularly weak at certain angles, the limit of the bar might be reached in the attempt to get a setting. In such case it is necessary to stop down the temporary standard, and to again refer it to the reserve. It may be added that the reserve is never allowed to burn more than a few minutes, and cannot possibly deteriorate under such conditions of use. With this disposition of the mirrors, the angle of incidence at the photometer disc is constant. In Fig. 1 this angle is shown at more than twice its actual value in order to reduce the length of the drawing. The real value of this angle was 5° – 54′. To make a correction for this lack of normal incidence would mean the division of the intensities, as found, by the cosine of 5° – 54′, or ·9947. Failure to do this introduces an error of about one-half of 1 per cent., which is clearly negligible in work of this character. It is, of course, necessary in testing sources with large globes or shades to use mirrors of size such that the globe or shade may be seen in its entirety when the eye is placed at the point C (Fig. 1); and it is further necessary that the distance *a b c* should be large. It is important to note that the double-mirror method, while enormously diminishing the fluctuation due to wandering of the arc, can have no effect on such fluctuations as are due to variations in length of the arc, or to variations in the current.

A preliminary test of much interest is described as follows: "When an opalescent inner globe is used, the globe itself becomes more or less luminous by diffusion. The diffusion differs with the height of the arc in the globe; that is to say, with the length of the lower carbon. To ascertain the magnitude of this effect, I have carried through three tests on the same lamp and inner globe, and also the same carbons, the lower carbons being cut successively to the lengths of 4¾in., 2¾in., and 1¼in. The results appear in Fig. 2. In every case the arc was placed at the centre of the mirror system." An inspection of these results shows that least light is obtained with the arc at the top of the globe, and most light when the arc is at the mid-point. This is explained in part by the fact that, with the arc at the top, a good part of the luminous flux is incident upon the non-reflecting surface of the gas cap. While the second and third positions yield a considerably increased flux of light with a clean globe, they must be considered as impossible conditions in practice, since by the time the arc has descended to these points the globe has received a coating. The net result, then, as the lamp burns is due to an increase in light flux due to the descending arc, and a diminution in light flux due to the formation of a coating. How this affects the quantity of light emitted—*i.e.*, the product of flux and time integrated throughout the life of the carbons—is a subject for future investigation, and involves the questions of carbons, shape of globes, etc. In the tests the initial condition, the simplest to obtain, was chosen, even though the light emitted may be less than at some subsequent period in the life of the carbons.

The first investigation taken up by Prof. Matthews was intended to settle the status of the 110-volt direct-current enclosed arc lamp as found in its commercial form to-day. Reports are made upon eight different lamps of this tyye.

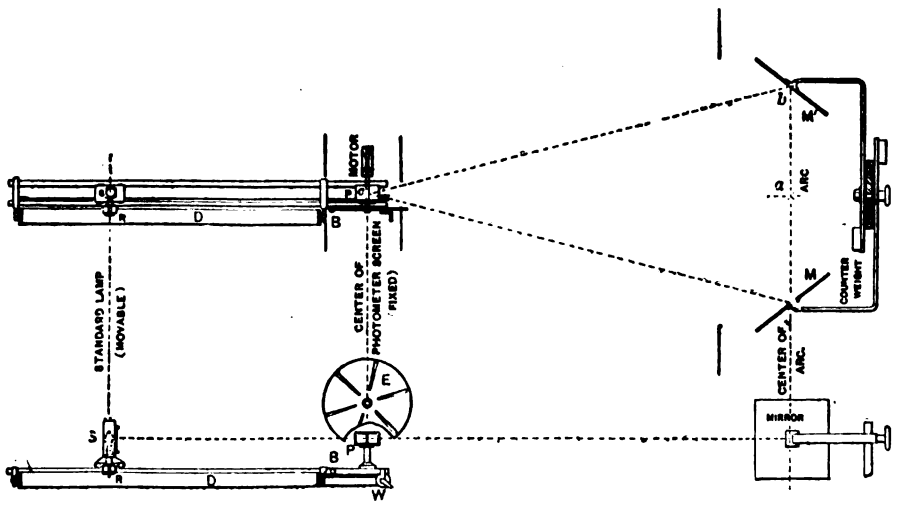

FIG. 1.

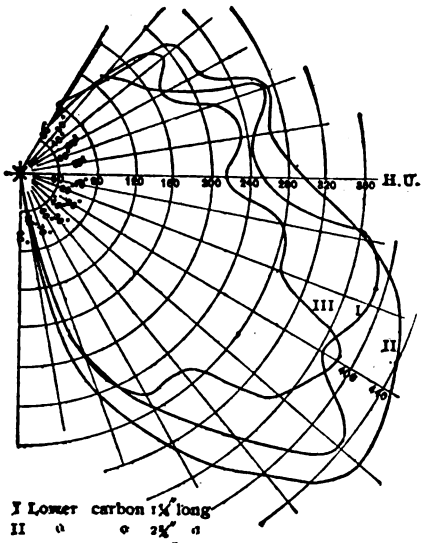
The tests were made upon the lamps as sent by the makers, but with a certain uniformity in conditions. These conditions are: (1) the same brand of carbons throughout; (2) an opalescent or milky inner and a clear outer globe, as supplied; (3) an opalescent inner and an opal ground, or milky outer globe, as supplied. Thus there are two regions where curve II. extends beyond curve I.

Fig. 3 shows the results of a representative test on one of these lamps. The regularity and relative position of these curves are indicative of the accuracy of the methods employed. The curves show very clearly the slight absorption of the clear outer and the large absorption of the opalescent outer. The clear outer globe shows some diffusion, as it tends to round out the curve. In the case of the opalescent outer globe, the diffusion is so marked that the luminous intensity is practically constant throughout a very large solid angle. In the higher angles above the horizontal the intensity is greatly increased, producing the effect, approximately, of a luminous sphere of equal intrinsic brightness. This results in the elimination of shadows, and the production of a pleasing light for interiors. The quality of light is also changed to a considerable extent through the absorption of the excess of violet rays otherwise very marked in the light of the arc. This result is attained, however, at a diminished efficiency. In this and nearly all the curves with the opalescent outer globes, a certain wavy outline is noticed. This effect is due, in large part, to the variations in the diffusive power of the globe itself. One finds difference in thickness and translucency to a considerable extent in such globes, and as the angle

Digitized by Google

of view changes these differences would tend to distort the distribution curve.

At a common terminal E.M.F. of 110 volts, seven of these lamps take an average current of 4 90 amperes, which means an average total power consumption in each lamp of 539 watts. With 80 volts at the arc, this power is divided into 147 watts waste in the resistance coils and 392 watts



I Lower carbon 1¼" long
II " " 2½" "
III " " 4½" "

FIG. 2.

in the arc. The average yield of light, expressed as mean spherical intensity, is:

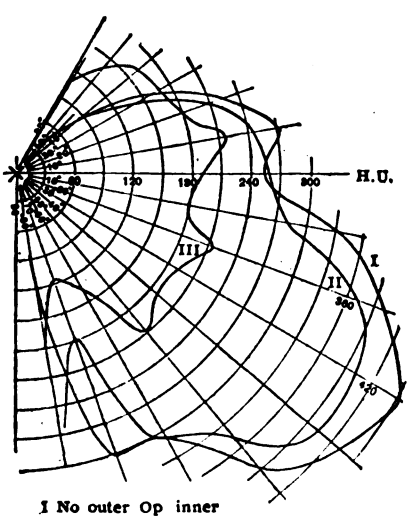
Opalescent inner, no outer*	256 H.U.
Opalescent inner, clear outer	207 H.U.
Opalescent inner, opalescent outer	177 H.U.

* The computations for no outer globe have not the same value as the others, for the reason that the number of such tests was less.

Hence the power required to produce one unit of light in this type of lamp is:

Opalescent inner, no outer	2·10 watts.
Opalescent inner, clear outer	2·66 watts.
Opalescent inner, opalescent outer	3·04 watts.

Attention was called to the fact that these figures give the value of this type of lamp as a light producer, and not



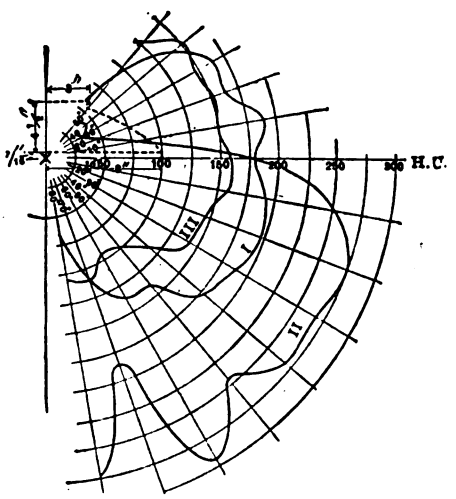
I No outer Op inner
II Clear " " "
III Op. " " "

FIG. 3.

a light distributor. The efficiency of the type as a distributor of light can best be found from a consideration of the curves of illumination—a matter which does not form a part of this investigation.

The second investigation reported deals with the general status of the 110-volt, alternating-current, enclosed arc lamp in its commercial form. Conditions similar to those described in the preceding tests obtained throughout this investigation. Seven lamps were subjected to tests. Of the results, none are more instructive than those obtained on lamp 106 (Fig. 4). The highly beneficial effect of a shade on an alternating-current lamp is here well shown. The large upward lobe of the distribution curve is intercepted and turned into useful directions. It is to be remembered that these distribution curves represent the state of affairs when the lamp is newly trimmed. As the arc burns lower, the upward flux of light is strengthened and the value of the lamp as a light source improves, because the shade then reflects a larger flux of light into useful directions. The shade in this case extends downward to a plane about ½in. above the arc, when the latter is at its highest point. The horizontal intensity with shade is slightly less than with clear outer globe, showing that the latter strengthens this intensity by diffusion more than it reduces by absorption. The increase in intensity from the horizontal to 20deg. B is very marked when the shade is employed in the position here indicated, and these are angles of most importance in street-lighting, if not in interiors. The mean hemispherical intensity is altered by the substitution of the shade for the clear outer globe in the ratio of 254 : 169, or 50 per cent. increase. It is worth noting that the curvature of this shade is admirable for the effect sought. A shade which is concave outwards will divert a portion of the luminous flux upwards, where it is largely dissipated by absorption.

As to the efficiency of this type of lamp, the following table gives a recapitulation of the power measurements on the alternating-current lamps. The mean power consump-



I Op inner Clear outer
II Op. " Shade
III Op. " Op. outer

FIG. 4.

tion of seven lamps is 417 watts. The average value of the mean spherical intensity is:

With clear outer globe	159 H.U.
With opalescent outer globe	130 H.U.

Therefore, as light producers, the average efficiency is:

With clear outer globe	2·62
With opalescent outer globe	3·20

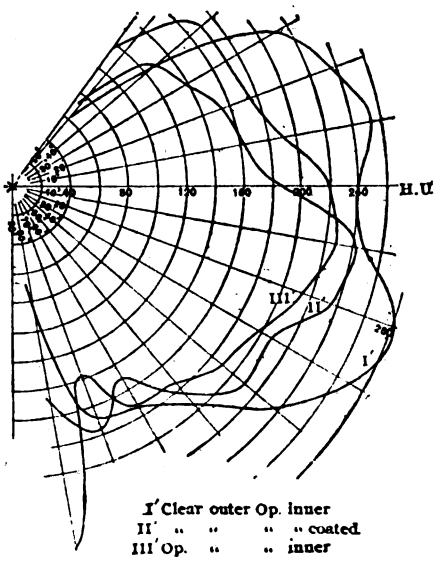
In watts per mean spherical Hefner unit. The mean power in the arc is 342 watts, and in the mechanism 74 watts.

On the Relative Merits of the Direct-Current and Alternating-Current Lamps as Light Sources.—Regarding these lamps merely as light producers, the average direct-current lamp yields, with opalescent inner and a clear outer globe, 207 H.U., whereas the average alternating-current lamp for circuits of the same pressure yields 159 H.U., which gives the former lamp an advantage as a light source, irrespective of efficiency, in the ratio of 48 : 159, or 30 per cent. It is pretty well demonstrated that the alternating arc is *per se* less efficient than the direct-current arc. Just what the proper ratio may be is a matter for physical research, and varies with several factors, such as current density, wave form, etc. Comparing the average performance of the lamps in the first series of tests with the average performance of the lamps in the second series of tests, one finds very nearly the same power consumption per light unit—viz.:

	D.C.	A.C.
Clear outer	2·66	2·62
Opalescent outer	3·04	3·20

Digitized by Google

The difference is slightly in favour of the alternating-current lamp in the first case, and somewhat more in favour of the direct-current lamp in the second. To compare the direct-current lamp with the alternating-current lamp on the basis of mean spherical intensity is not always fair. When an outer diffusing globe is used, this basis of comparison is correct enough, for the reason that the distribution of intensity is fairly constant in all directions both for the direct and alternating current types. For outdoor use,

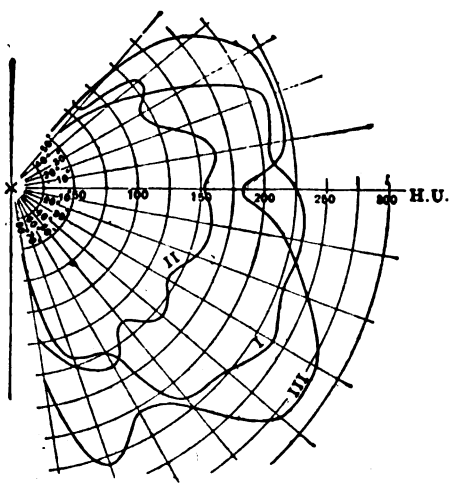


I' Clear outer Op. inner
II' " " " " coated
III' Op. " " inner

FIG. 5.

however, lamps will be provided with inner globes only, or clear outer globes, or shades, as the case may be. In any event the upward luminous flux which passes the globes or shades is practically of no utility. Hence, for outdoor use, the mean hemispherical intensity below a plane passing through the arc is a better basis for comparison.

The average direct-current lamp in this series of tests yields a mean hemispherical intensity of 273 H.U. with clear outer globe. The average alternating-current lamp yields but 190 H.U. This gives the former an advantage



I Op. inner: Clear outer
II Op. " : Op. "
III Op. " coated : Clear outer

FIG. 6.

as a useful light source represented by the ratio of 83 : 190, or 43 7 per cent. Moreover, the power required per unit intensity is in the two cases 1·97 watts and 2·19 watts per mean hemispherical H.U., so that not only does the direct-current lamps with clear outer globes give a stronger mean intensity below the arc, but it does so at a higher efficiency. But it is wasteful to use an alternating current lamp for street-lighting without a shade or reflector. The tests on lamps 102 and 106 enable one to draw certain interesting comparisons. They give mean hemispherical intensities respectively of 266 and 254 H.U., or very nearly the same as the average direct-current lamp with clear outer. This yield is obtained at a power consumption of only 418 watts, which is 1·61 watts per H.U. This emphasises the great importance of a shade on the alternating-current lamp. Finally, comparing this last result with the performance of direct-current lamp 1, with no outer globe and no shade, the mean hemispherical intensity is 362 H.U., the power consumption 558 watts, and the power per H.U. 1·54 watts. The conclusion based on this single comparison is that for street-lighting, the direct-current lamp without shade gives 39 per cent. more useful light than the alternating-current lamp with shade, and at slightly greater economy. The accompanying table gives the summarised results of the preceding investigations:

* Condition of no outer globe. † Condition with shade on lamp. A. Power factor lamp. B. Power factor arc. Note.—All marked values not included in the mean.

The report concludes with a description of certain preliminary experiments to determine the amount of light absorbed by the coating of ash formed on the inner globe of the enclosed arc, and the time law of its formation. But two representative examples of these measurements are here given. Fig. 5 refers to a direct-current lamp having a large inner globe of the closed-bottom type. Curve I.' shrinks to curve II.' in 106 hours, and the absorption is 16·6 per cent. In Fig. 6, which represents the result of a coating test on an alternating-current lamp, one finds the striking result of more light with coating than without. The absorption is 12 5 per cent. It is important here to remember that, with the arc at the top, the strong upper lobe of the distribution curve of the alternating arc is very much curtailed. Now, as the arc lowers this lobe unfolds, as it were. In 70 hours' time the coating has not formed with sufficient rapidity to offset this increase in luminous flux. Hence the result shown.—*Electrical World.*

Krupp's Works, Essen.—Some idea as to the extent of the electrical installation at Krupp's Works, Essen, where upwards of 27,000 workpeople are employed, may be gathered from a few bare facts. The supply of electricity to the works for lighting and heating purposes is provided for by three generating stations and six distribution sub-stations. Radiating from these are 26 85 km. of underground feeder cables and 90 km. of overhead distributor cables, which supply energy to nearly 900 arc lamps, 6,724 incandescent lamps, and 179 electromotors. That the electric generating plant in its present capacity by no means satisfies the existing demand for light and power is betrayed, however, by the mention in last year's report of the concern of about 19,000,000 cubic feet of gas generated and consumed at the works.

BURY ELECTRICITY ACCOUNTS.

From the accounts of the Bury Corporation electric light department, just issued, it appears that the total expenditure on capital account to March 31, 1900, amounts to £40,715. An abstract of the revenue account, balance-sheet, and statement of electricity generated, sold, etc., is given herewith:

REVENUE ACCOUNT.

BRISTOL ELECTRICITY WORKS.

The following is the report of the Electrical Committee to the City Council on the working of the electrical department for the year ended March 25, 1900, and shows an expenditure to date on capital account of £252,588. An abstract of the revenue account, balance-sheet, and statement of electricity generated, sold, etc., together with a further reference to the report, and a curve showing the progress of the undertaking, will be given in a future issue.

The number of consumers on March 25, 1900, was 1,215, being an increase of 248 during the year. The number of lamps connected was 85,956 (of 8 c.p.) as compared with 68,536 at the corresponding period of the previous year. During the year a number of motors have been connected with the mains. The use of electricity for motive power in Bristol is in its infancy, and judging by its extensive use for similar purposes in other towns, your committee anticipate a much larger demand when its advantages are better known. The number of units sold was 1,812,511, being an increase of 449,725. An examination of the accounts will show that the financial results of the year have been satisfactory, considering that the effect of the reduction in the charges for private lighting made on Oct. 1, 1898, and for public lighting made on Jan. 1, 1899, has been felt throughout the year, whilst only a part of the previous financial year was affected. The gross receipts amounted to £31,717. 14s. 2d., and the gross expenditure to £17,962. 1s., leaving a gross profit of £13,755. 13s. 2d., from which has to be deducted: interest on loans and bankers' overdraft, £6,019. 15s. 8d., and repayment of money borrowed, £7,590, leaving a balance of £145. 17s. 6d. The following statement exhibits the financial position of the undertaking at March 25, 1900: total capital expenditure, £252,588. 7s. 2d.; mortgage debt, less paid off or set aside, £198,620; balance at credit of reserve fund, £5,000; balance at credit of depreciation account, £2,024. 17s. 7d.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

295. What is the best arrangement and the best machinery to use to run 14 direct-current arcs taking 25 amperes?—A. SMYTH.

296. In a continuous-current circuit, three-wire system, with 120 volts in the mains, which is the best way for supplying power in the daytime at 240 volts without any trouble, with the supply of light in the evening at 120 volts? It is needed that power cannot be used in the evening, nor the light in the daytime.—CIENFUEGOS, CUBA.

[This question wants a little in clearness, but we think readers will fully understand it, and, as it comes from friends across the sea, we trust the replies will enter a little into detail.—ED. *E. E.*]

ANSWERS.

289. What is the best method of determining the counter E.M.F. of electrolytic baths?

Answer to No. 289 *(awarded* 10*s.).*—The difference of pressure, E, between the electrodes of a cell through which a current, C, is passing may be written:

$$E = K + R\,C,$$

where K is a constant (the counter E.M.F. of the bath), and R is the resistance interposed by the electrolyte to the passage of the current. If we put

$$C = 0$$

in this equation, we find that

$$E = K.$$

Thus K, the counter E.M.F. of the bath, is equal to that E.M.F. which will just drive an indefinitely small current through the bath.

The value of K may be measured in a variety of ways:

1. Measure the difference of pressure, E_1, between the electrodes when an observed current, C_1, flows through the cell. Then change the current to C_2, and measure the corre-

Digitized by Google

sponding difference of pressure, E_2. An ordinary voltmeter and ammeter may be used for these measurements. Then

$$E_1 = K + R C_1;$$
$$E_2 = K + R C_2;$$
$$\therefore K = \frac{C_2 E_1 - C_1 E_2}{C_2 - C_1}.$$

2. Measure the difference of pressure between the electrodes when a very small current is passing. (The current, C, must be so small that the product, C R, is negligible. R may be calculated from the dimensions of the cell and the specific resistance of the electrolyte.) This will obviously be equal to the counter E.M.F. of the bath.

3. Connect the electrodes of the bath with a suitable battery and a voltmeter by means of a key in such a manner that on depressing the key the battery circuit is broken, and the voltmeter is connected with its + terminal to the anode and its − terminal to the cathode of the bath. Then the reading of the voltmeter *immediately* after the battery circuit is broken will give the counter E.M.F. of the bath. An electrostatic voltmeter should preferably be used for this experiment.—E. E.

Answer to No. 289 (*awarded* 10*s.*).—The practical resistance of an electrolytic cell consists of two factors: firstly, the ohmic resistance of the electrolyte, and, secondly, the counter E.M.F. generated by the chemical reactions set up by the working current. The total resistance of an electrolytic plant comprises the above factors plus the ohmic resistance of the leads from the battery or from the dynamo-electric generator, whichever may be employed. Several methods may be used to determine the ohmic resistance and also the counter E.M.F.

When the energy is supplied from batteries or from accumulators, the simplest method to determine the counter E.M.F. is to suddenly, by a suitable switch, cut off the source of energy and connect the terminals of the electrolytic cell through an electrometer of high resistance (in the reverse direction to the working current), and compare the deflection with that obtained from a Clark's or other standard cell.

When employing dynamo-electric currents it would, however, not be advisable to adopt this method, owing to the risk of damage to the engine and to the dynamo by the sudden change from full load to no load. In such a case a better method would be as follows: First, run the dynamo at its normal speed with normal output. Allow ample time for the full counter E.M.F. of the electrolytic cells to be attained. Call the E.M.F. at the terminals of the dynamo E and the current C. Next increase the speed (say 10 per cent.), again allowing ample time for the counter E.M.F. of the cells to attain its maximum.

Let a = the increased current at the higher speed;
b = the increased E.M.F. at the higher speed;

then the new readings will be $E + a$ for the E.M.F. and $C + b$ for the current.

Let R = the total resistance of the outer circuit brush to brush;
Y = the metallic resistance of the circuit, and
X = the counter E.M.F.;

then at normal speed we have

$$R = \frac{E}{C} \text{ and } Y = \frac{E - x}{C},$$

and for the increased speed

$$Y = \frac{E + a - x}{C + b}.$$

Whence
$$X = (E - a) - \left(a \frac{C - b}{b} \right)$$
$$= E - \frac{a C}{b};$$

and
$$Y = \frac{a}{b}.$$

For example, at normal speed the readings are E = 5 volts, C = 50 amperes, and at the increased speed $E + a$ = 6 volts, and $C + b$ = 70 amperes, and hence a = 1 volt and b = 20 amperes. Then

$$R = \frac{E}{C} = \frac{5}{50} = 0{\cdot}1 \text{ ohm};$$
$$X = E - \frac{a C}{b} = 5 - \frac{1 \times 50}{20} = 2{\cdot}5 \text{ volts};$$
$$Y = \frac{E + a - X}{C + b} = \frac{5 + 1 - 2{\cdot}5}{50 + 20} = 0{\cdot}05 \text{ ohm}.$$

—W. G.

Answer to No. 289 (*awarded* 7*s.* 6*d.*).—The best method of determining the back E.M.F. or amount of polarisation in electrolytic vats is to fit the vat for the time being with insoluble electrodes, also providing a third thin metal plate so that it can be interposed when required between the anode and cathode, and the nature of this plate must be such as not to sensibly affect the resistance. Now, if E, P, C, R represent E.M.F., polarisation, current, and resistance respectively, then with the two electrodes we have $E_1 = P + C R$. If the third electrode be now interposed so as to completely divide the cell, and the resistance and current is maintained unchanged, then $E_2 = 2P + C R$, or, $P = E_2 - E_1$. In putting the method into practice the main difficulty is encountered in arranging the cell so that the third electrode may be put in or taken out easily, and in such a manner that the current shall pass through it and not round it.

In an actual experiment a rectangular cell of ebonite is provided with platinum electrodes which fit into grooves in the walls of the cell, and between these a third groove receives the third plate, which is placed in such a position so as to prevent undue leakage round the electrode with moderate conductivities and current densities.

About half an hour elapses before the polarisation becomes constant. The following are some results obtained:

Copper Sulphate, 16 *per cent. at* 15*deg. C.*

Current density, in amperes per square dcm.	Polarisation, volts.
·03	1·591
·06	1 628
·12	1 668
·2	1·695
·3	1·717

Silver Nitrate, Normal, 15*deg. C.*

Current density, in amperes per square dcm.	Polarisation, volts.

·03	·897
·06	·903
·12	·908
·2	·926
·4	·935

—J. C. B.

Answer to No. 289 (*awarded* 7*s.* 6*d.*).—The back E.M.F. may be easily calculated, as shown by the following considerations:

Let Q = quantity of electricity passed through an electrolyte (coulombs);
V = back E.M.F. (volts);
z = electro-chemical equivalent of ion deposited (grammes per coulomb);
J = Joule's equivalent of heat
= 42×10^6 ergs;
H = the heat of combination of the ion in question with the other resolved ion.

The work done is = V . Q × 10^7 ergs;
= Q . z . H . J.
$\therefore$ V = z . H . J × 10^{-7} volts.

An example may be useful—say, what is back E.M.F. in water voltameter?

Take from the tables—

$z = 1{\cdot}0384 \times 10^{-5}$ (hydrogen);
H = 3 4 × 10^4 (H and O).

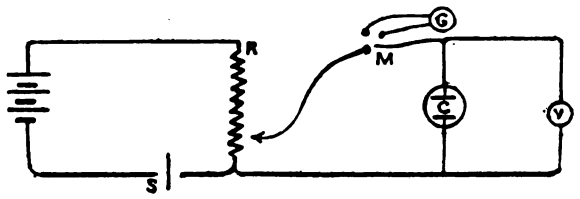
Hence V = z H J × 10^{-7};
= $1{\cdot}0384 \times 3\,4 \times 4{\cdot}2 \times 10^{-5} \times 10^4 \times 10^{-7} \times 10^7$
= 1·48284;

which is the required E.M.F. in volts.

A practical method may be given on this principle: that an applied E.M.F. exactly equal to back E.M.F. of electrolyte would not decompose it. But this would be a

Digitized by Google

laboratory experiment and not suitable for a workshop. There can be no rough-and-ready way of doing this. Fit up apparatus as shown:



C = the electrolytic cell;
V = voltmeter, Weston or Siemens;
G = galvanometer;
M = mercury-cups, and S a switch battery of preferably secondary cells;
R = rheostat.

Pass a current through the cell and decrease it by altering the E.M.F. by means of rheostat until the galvanometer indicates no current or as near to it as possible. Then read volts on voltmeter, which gives back E.M.F.

N.B.—A mean of several observations must be taken, and readings should be taken on both rise and fall of current.—A. S.

Question No. 290.—Give comparative figures as to the weights and efficiencies of two direct-current dynamos of about 200 kw. capacity, running at a speed of about 50 revolutions per minute, the first machine to be a two-pole one and the second a multipolar. Figures from actual machines would be of greatest service.

Best Answer to No. 290 (*awarded* 10*s.*).—Such an output as 200 kw. at 50 revolutions is entirely unsuited to a two-pole

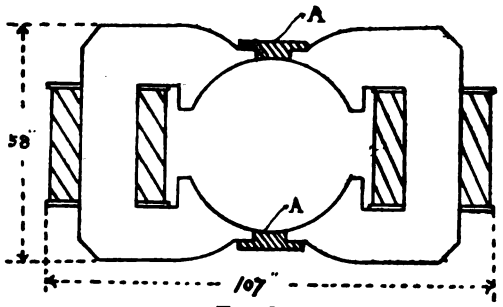


FIG. 1.

design, and it is most unlikely that anything approaching this has ever been actually made, the reason being that a multipolar machine can be made of very much less weight, as will be seen by the comparison given below. This com-

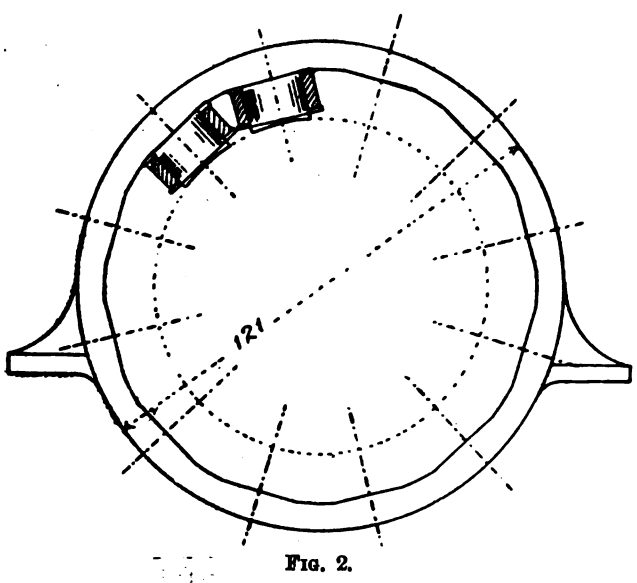

FIG. 2.

parison has been worked out on the basis of equal heating—a temperature rise of about 70deg. F. being allowed. Though the figures are not taken directly from actual machines, the multipolar is only slightly modified from existing machines to suit the output given, and the two-polar is based on machines of such outputs as 200 kw. to 300 kw. at 300 revolutions, which is the largest output for which two-polars are ever used at the present time. To give the two-polar every advantage, the Manchester type of magnet (Fig. 1) has been chosen, as this is not only considerably lighter than the equivalent single-limb magnet type, but also allows the poles to be conveniently split at the centre by a non-magnetic distance-piece (as shown at A, Fig. 1), which has the effect of practically halving the armature reaction, and thus allowing a much smaller air-gap to be used, without fear of sparking, than would otherwise be the case. Further, the two-polar is made with a smooth-cored armature, as a considerable air-gap is in any case necessary to prevent sparking, and may as well be occupied by the conductors. The multipolar is made with an ordinary slotted armature core, as is now almost the universal custom. The number of poles chosen is 12, but if this number is slightly reduced or increased, the effect on the total weight will not be great. The two figures shown are to scale.

COMPARISON.

	Two-polar. Fig. 1.	Multipolar (12 pole). Fig. 2.
Output	200 kw. at 50 revs.	200 kw. at 50 revs.
Diameter of armature core	40in.	80in.
Length of armature core	60in.	15in.
Net weight of armature copper (not including commutator)	40cwt.	15cwt.
Net weight of armature core discs	135cwt.	70cwt.
Armature hub, commutator, and spindle (approximate)	70cwt.	80cwt.
Net weight of magnet (iron or steel)	470cwt.	200cwt.
Net weight of magnet (copper)	105cwt.	35cwt.
Complete weight of machine exclusive of bearings and bedplate	850 cwt.	420 cwt.
Approximate commercial efficiency at full load	87 per cent.	89 per cent.
Approximate commercial efficiency at half load	85 per cent.	86 per cent.

Q.

LIGHT RAILWAYS.

The Light Railway Commissioners have submitted to the Board of Trade an order for the construction of a light railway in the county of Gloucester, between Wotton-under-Edge and Charfield.

The Carnarvon County Council have approved of the application of the North Wales and District Light Railway and Electric Power Syndicate, Limited, for the loan of £5,500 to enable them to construct a light railway from Pwllheli to Morfa Nevin, on condition that the promoters of the railway provide a roadway along the whole of the route of a width of not less than 19ft. 6in. from the end of the sleepers to the foot of the hedge, and also that the top of the sleepers be made level with the surface of the roadway, and that all occupation and public crossings are paved.

At the meeting of the Surrey County Council a resolution to the effect "that a committee be appointed to consider the position this Council should assume with relation to all applications to the Light Railway Commissioners and to Parliament for powers to construct light railways and tramways within the administrative county, and to report to this Council thereon," was considered and lost.

At the last meeting of the Gwyrfai District Council a joint committee of Pwllheli Town Council and the Gwyrfai Council recommended that of the two schemes for the construction of a light railway to Dinas Dinlle, the one submitted by Mr. Peterson, of London, on behalf of a syndicate, should be considered favourable by the two authorities.

The Light Railway Commissioners on Friday last held an enquiry in reference to an application for an order authorising the construction of a light railway from Bury St. Edmunds to Attleborough. The Commissioners having discussed the plans for a few minutes, the President said an order for the construction of the amended scheme, that was to say, a line from Bury to Diss, with a short branch from Stanton to Walsham-le-Willows, would be granted, subject to the approval of the Board of Trade.

An enquiry was held last week by the Light Railway Commissioners into an application by Messrs. H. H. P. Bouverie, A. Peace, and R. A. Read for an order authorising the construction of a light railway between Bridgwater, Cannington, Bolam Bridge, Fiddington, Stowey, and Stogursey. This order was granted.

Digitized by Google

The Oxford County Council have passed a resolution to apply to the Railway Commissioners authorising them to make under certain conditions a grant of £15,000 towards the construction of the Witney, Burford, and Andoversford Light Railway.

In connection with the scheme now before the Light Railway Commissioners for the construction of light railways between Blackburn, Burnley, and Whalley, the Tramways Committee of the Blackburn Corporation have approved a proposal to form a tramway from Furthergate to the borough boundary in Burnley-road. The cost is estimated at £15,000, and the connection would bring practically the whole of East Lancashire into the system.

The Light Railway Commissioners have refused the application of Mr. Henry Brinsley Sheridan, J.P., and Mr. Thomas W. Barber, M.I.C.E., for powers to construct a series of light railways for South Devon.

MANCHESTER ELECTRICITY WORKS.

The following is the report of the Electricity Committee for the year ended March 31, 1900, together with an abstract of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc.:

The total quantity of electricity measured and accounted for during the past 12 months amounted to 6,468,405 units, being an increase of 1,254,184 units, or 24 per cent., over the previous year. The number of consumers at the close of the year was 3,240, representing an increase of 670 as compared with the preceding year. The total number of lamps connected was: incandescent (of 8 c.p.) 237,145, arc 2,139, as compared with 188,999 and 1,817 respectively. There were also in use 500 motors, representing 2,050 h.p., showing an increase on the previous year of 166 motors, equivalent to 890 h.p. The maximum load at any time during the year was 5,607,000 watts. During the past year additional mains have been laid to the extent of 83,250 yards, or 47 miles 530 yards, making the total length laid at March 31, 110 miles 45 yards.

The revenue derived from sales of current, etc. (which works out at 3·20d. per unit accounted for) amounts to		£86,297 18 4
And the working expenditure to		49,905 11 6
Showing a gross profit of		£36,392 6 10
Out of this sum, the following requirements had to be met—viz.:		
Interest on mortgage debt, etc.	£14,264 15 0	
Sinking fund	12,935 0 5	
		27,199 15 5
Showing a surplus or net profit of		£9,192 11 5
This surplus, together with the balance of £2,000 brought from last year's account and £572. 6s. 5d. interest on reserve fund investment, making a total of £11,764. 17s. 10d., has been appropriated in the following manner—viz.:		
Paid to city fund in aid of rates		£10,000 0 0
Placed to reserve fund		1,764 17 10
		£11,764 17 10

The following statement exhibits the financial position of the undertaking at March 31, 1900:

Total capital expenditure		£641,821 18 0
Mortgage debt		556,278 9 0
Amount of mortgages redeemed to date by action of sinking fund		49,232 11 0
Balance at credit of renewals suspense account		335 4 5
Ditto reserve fund		13,360 15 2

Owing to the necessity for renewing a considerable length of mains which had proved defective, the charge upon revenue account for repairs and renewals of mains this year amounts to £7,453. 10s. 6d., as against £1,495. 12s. 6d. last year. In addition to this, the sum of £12,459. 10s. 6d. has been taken from the renewals suspense account to cover similar expenditure. Your committee regret that the accident which happened to the machinery at Dickinson-street station in September last did considerable damage to a portion of the plant installed there. Two 400-h.p. engines and dynamos were completely wrecked; whilst other engines, a switchboard, a range of steam-pipes, and the building were also damaged. The amount withdrawn from the reserve fund on account of the breakdown is £7,069. 18s. 1d. The parts of the two wrecked engines and one horizontal engine have since been sold, and on the space set at liberty two new direct-driven generators, each of 1,000 h.p., will shortly be erected. These machines will be suitable for lighting and tramway work. The work in connection with the foundations and buildings at Bloom-street generating station is proceeding with all dispatch, and the several contractors for the supply of engines, generators, boilers, etc., have the plant in a forward state. Your committee are pushing forward the equipment of this station in order to meet the increasing demand for the supply of electrical energy, and to be ready to supply the current necessary for working the tramcars. At the Polygon, Ardwick, satisfactory progress is being made with the erection of buildings for workshops and cable stores, etc., and it is expected they will be ready for occupation before the end of the present year. Your committee have recently approved of plans for the equipment of a part of Stuart-street generating station, and specifications for the various works will shortly be issued. Very considerable progress has been made during the past year with the laying of electric mains in the districts of Withington, Moss Side, and Levenshulme. The supply of current has been available in portions of Moss Side since December last, and in Withington since February last. On Sept. 30 last the price of electric energy to long-hour consumers was reduced from 1½d. to 1¼d. per unit, and a similar reduction was made in the price of current supplied for motor purposes. The above represents a concession to the consumers of £2,873. 8s. 6d. in six months.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Halifax.—Tenders for incandescent lamps are required by the Corporation.

Luton.—The Electric Lighting Committee invite tenders for the supply and erection of meters.

Lincoln.—The Town Council invite tenders for wattmeters and demand meters. Tenders by Sept. 14.

Hamburg.—Two 30-ton electric cranes are required. Enquiries may be made at the Town Hall. Tenders by Sept. 10.

Warrington.—Tenders are required by the Corporation for installation of mains and fittings at town hall and market.

Barcelona.—The Public Works Department, Madrid, invite tenders for a system of electric tramways in Barcelona. Tenders by Aug. 18.

Plumstead.—The Vestry invite tenders for the supply and erection of various plant and machinery for electricity works. Tenders by Sept. 15.

Portsmouth.—The Electric Lighting Committee invite tenders for carrying out the street work required for laying cables, etc. Tenders by 15th inst.

Leeds.—The Guardians invite tenders for the installation of electric light to the Poor-Law Offices, East-parade, Leeds. Tenders by 14th inst.

Newport (Mon.).—The Guardians invite tenders for a complete installation of electric light at the new workhouse, Stow-hill, Newport. Tenders by 22nd inst.

Belfast.—The Electricity Committee invite tenders for the supply and erection of an auxiliary feed-water heater with pipe connections. Tenders by Aug. 15.

Stockport.—The Tramways Committee invite tenders for 20 double-deck tramcars, complete with electric equipment for overhead traction. Tenders by Aug. 31.

Bradford.—The Guardians invite tenders for the installation of electric lighting at their union workhouse. Tenders by Aug. 13. Details in our advertisement columns.

Leeds.—The Tramways Committee invite tenders for the erection of a new boiler-house (all trades except ironfounders') at the generating station, Crown Point, Leeds. Tenders by 21st inst.

Salford.—The Corporation invite tenders for the supply, delivery, and erection of lighting cables, tramway feeders, and street lighting. Tenders by Aug. 13. Details in our advertisement columns.

Barnes.—The Urban District Council invite tenders for the supply and erection of pipework, condensers, etc., and overhead travelling crane. Tenders by Aug. 14. Details in our advertisement columns.

Cupar Fife.—Tenders are invited at once for an electric lighting installation at the Fife and Kinross District Lunatic Asylum, about 800 lights. Apply to Mr. D. Osborne, clerk to the Board, Cupar Fife.

Newcastle-on-Tyne.—The Corporation invite tenders for the laying down in Newcastle of about five miles of double-line tramway, the rails and fastenings and the poles being supplied by the Corporation. Tenders by Aug. 22.

Edinburgh.—The Lord Provost, Magistrates, and Council are prepared to receive tenders for coal-conveying machinery for Dewar-place station, contract No. 54. Tenders by 13th inst. Details in our advertisement columns.

Aberdeen.—The Corporation Tramways Committee invite tenders for the supply of steel poles, bases, and brackets for extensions of their overhead system of tramways. Tenders by 25th inst. Details in our advertisement columns.

Fulham.—The Vestry invite tenders for wiring the town hall, Walham Green, for the electric light. Tenders by 24th inst. Details in our advertisement columns.

Salford.—The Corporation invite tenders for the supply, delivery, and erection of the following plant: lighting switchboard, traction switchboard, and balancing transformers at their new electricity works, Strawberry-road, Pendleton. Tenders by Sept. 3. Details in our advertisement columns.

Whitby.—The Council invite tenders for the following plant: two water-tube boilers, pumps, condensers, pipes, etc., two steam dynamos, balancer, and boosters, switchboard and connections, battery, travelling crane, and cables, arc lamps, etc. Tenders by Sept. 3. Details in our advertisement columns.

Portsmouth.—The Corporation invite tenders for the supply, delivery, and erection of the whole of the plant and apparatus necessary to completely equip for electric traction their proposed power station at Vivash-road, Fratton-grove, Portsmouth. Tenders by Sept. 4. Details in our advertisement columns.

Grimsby.—The Corporation invite tenders to specification for the supply and delivery, in connection with the electric lighting of the borough, for additional steam dynamos: Section 1, engine; Section 2, dynamo; and extension of switchboard for dynamo No. 7, and traction work. Tenders by 18th inst. Details in our advertisement columns.

St. Petersburg.—The Posts and Telegraphs Department invite tenders for the working of the telephone systems in St. Petersburg, Moscow, Warsaw, Odessa, and Riga for 18 years from Nov. 1, 1901. Tenders by Aug. 28. All necessary particulars may be examined on personal application at the Imperial Russian Financial Agency, 107, Cromwell-road, London, S.W., on Mondays, Wednesdays, and Fridays, from 2 to 4 p.m.

Aberdeen.—The Town Council invite alternative tenders for the supply of 650 tons steel girder straight-track tramway rails, weight about 100lb. per lineal yard; 150 tons steel girder curve-track rails, weight about 104lb. per lineal yard, in standard lengths of 60ft. or 45ft., as may be decided; also for 60 tons fishplates, weight about 75lb. per pair. Tenders by 24th inst. Details in our advertisement columns.

Hanley.—The Electric Lighting Committee invite tenders for the supply, delivery, and erection complete of two Lancashire boilers and fittings, including steam receiver; water-tank, girders, and pumps; fuel economiser, with engine or motor; smoke chimney, exhaust fan, with engine, etc.; feed-water heater; forced-draught fittings, firebars, or other appliances to boiler furnaces; and coal conveyor and bunkers. Tenders by 25th inst.

London, S.E.—The Directors of the South London Electric Supply Corporation, Limited, invite tenders for the supply and erection at their works at Bengeworth-road, Loughborough Junction, S.E., of a complete condensing plant for dealing with 28,000lb. of steam per hour, comprising surface condenser, steam-driven air and circulating pumps, cooling tower, and pipe connections. Tenders by 14th inst. Details in our advertisement columns.

Fenton (Staffs).—Tenders are invited for works in connection with the construction of a single line of railway (2ft. 6in. gauge) from Waterhouses to Hulme End, Staffordshire (about eight miles two furlongs), and incidental works connected therewith, for the Leek and Manifold Valley Light Railway Company. Plans, specifications, bills of quantities, and forms of tender may be inspected at the offices of the company's engineer, Mr. Joseph Forsyth, Heron's Cross, Fenton, Staffs, on and after Aug. 4, and copies of same may be obtained from him. Sealed tenders must be sent to Mr. Edward Challinor, secretary, Leek, by Sept. 1.

London, W.—The Central Electric Supply Company invite tenders for the supply, delivery, and erection of (Specification 2A) dry-back marine boilers, 11ft. 6in. diameter and 14ft. long, gangways, feed and drain pipes, etc., complete, as required for each of three blocks of boilers. Each or all of the blocks can be tendered for, each block containing six boilers. Tenders are also to be submitted for mechanical stokers, with the shafting and gearing for driving them. Alternative tenders are invited for (Specification 2B) water-tube boilers as an alternative to the dry-back marine boilers, including the mountings, feed and drain pipes, etc. Copies of the specifications, with forms of tender, drawings, and general conditions, can be obtained from the General Manager, 19, Carnaby-street, Golden-square, W., on payment of £3. 3s., to be returned on receipt of a bona fide tender. Specifications and drawings can be seen at the office of Prof. Kennedy, 17, Victoria-street, S.W. Tenders, on the prescribed form, endorsed on the outside "Electric Plant—Tender to No. — Specification," must be sent to Mr. F. J. Walker, general manager, before 10 a.m. on Aug. 20.

London, E.C.—Tenders are invited by the Pacific Cable Committee on behalf of her Majesty's Government and the Governments of Canada, New South Wales, Victoria, New Zealand, and Queensland for the manufacture and laying in the Pacific Ocean of 8,272 nautical miles of telegraph cables between Vancouver and Fanning Island, Fanning Island and Fiji, Fiji and Norfolk Island, Norfolk Island and New Zealand, Norfolk Island and Queensland. It is proposed to divide the whole undertaking under three distinct contracts, for any one or more of which contractors may tender. Each of these contracts will include a clause under which the contractor guarantees the good electrical condition and working order of the cables for 30 consecutive days after the completion of the laying. A fourth contract is also proposed for surveying and sounding the whole route before the cables are laid. Forms of contract, specification, and tender may be obtained of Messrs. Clark, Forde, and Taylor, 4, Great Winchester-street,

Digitized by Google

E.C., at whose offices charts showing the proposed route of the cable and the positions where soundings are to be taken may be inspected. The last day for the reception of tenders is Aug. 14. They must be enclosed in sealed covers, marked "Tender for Pacific Cable," must be addressed to Messrs. Clark, Forde, and Taylor, 4, Great Winchester-street, E.C., and must be delivered by 12 noon on that day.

RESULTS OF TENDERS.

Beckenham.—The following tenders have been received for the work of fencing at the electric lighting station: Nightingale, £197. 10s. 6d.; T. W. Jones, £203. 10s.

Barton.—The Guardians have accepted the tenders of the Lancashire Dynamo Company for a switch for the new motor at £11. 15s., and for the new dynamo at £50.

Manchester.—Messrs. W. T. Glover and Co., Limited, of Trafford Park, Manchester, have secured from the Corporation a large order for their diatrine paper cables.

Hapton.—The Parish Council have accepted the tender of Simpson Bros., of Hapton, at £122, for the lighting of Hapton township with electricity from Sept. 1, 1900, to April 30, 1901.

Birkenhead.—The Corporation have accepted the tender of Messrs. Stirling and Hughes, of Bootle, for constructing and erecting a new car shed in connection with the electric tramways in Laird-street, Birkenhead.

Liverpool.—A contract has been entered into with Willans and Robinson, Limited, Rugby, for the supply and delivery of three sets of plant similar to those on order for the Lister-drive and Pumpfields stations, at £6,939 per set, less 2½ per cent.

South Shields.—The Guardians have accepted the following tenders: Falconar, Bell, and Co., for the installation of the electric light at the workhouse, £1,969; W. Christie, for the erection of a dynamo-room, extension of boiler-house, and providing a new boiler, £1,224. 19s. 6d.

Bermondsey.—The Vestry have received the following tenders for the erection of a generating station in Neckinger, Spa-road:

G. E. Todd and Co., 192, Hackney-road, N.E. (accepted)...	£12,723
A. Johnson and Co., 66, Watling-street, E.C.	13,890
Hughes and Stirling, Arundel-street, Strand	14,791

BUSINESS NOTES.

TRACTION.

Sunderland. — A Board of Trade inspection of the new electric tramways in Sunderland was announced for the 9th inst.

Torquay.—The Electric Light Committee have been instructed to report upon the desirability of an electric tram scheme for the extended borough.

Darwen.—A sub-committee consisting of the Chairman, Vice-Chairman, Alderman Cocker, Councillors Cooper and Walmsley has been appointed to deal with tramway matters.

Bath.—From the local Press we gather that the tramway scheme which is on foot has the approval of every local authority interested, and the support of the inhabitants without as well as within the borough.

Southend.—The Town Council have accepted the tender of Messrs. Smith, McMillan, and Co., London and Philadelphia, at the price of £87,500, for carrying out a system of electric tramways for the borough.

Cheshire.—The application of the United Kingdom Tramway, Light Railway, and Electrical Syndicate, Limited, for the consent of the Council to the laying of the proposed tramways in the Cheshire salt district has been referred to the Parliamentary Committee of the County Council.

Norwich.—After a trial of two days the electric tramways of Earlham, Dereham, Thorpe, and Magdalen roads were opened to the public on July 30. During the first day 26,000 passengers were carried, representing an income of £108. During the three first days 73,000 passengers were carried.

Halifax.—The work at the King Cross and Warley-road tramlines is now almost completed. It will be some time, however, before this section is connected with the Highroad Well route, as the roadway which branches from Warley-road into Gibbet-lane, along which the trams will travel, requires widening.

Central London Railway.—The receipts for the first week amount to £4,323. The number of passengers were as follows: Monday, 85,400; Tuesday, 91,900; Wednesday, 86,700; Thursday, 96,100; Friday, 80,700; Saturday, 102,790. On Bank Holiday the line conveyed 100,391 passengers, and on Tuesday 105,171.

Burnley.—Notice is to be served upon the Burnley and District Tramways Company, Limited, requiring them to sell to the Corporation, under the conditions provided by Section 43 of the Tramways Act, 1870, so much of their undertaking, including line, buildings, rolling stock, etc., as are within the borough of Burnley. The Council have secured the services of Major Cardew as consulting engineer.

Automobile Association.—In the Chancery Division on Wednesday Mr. T. R. Warrington, Q.C., moved, before Mr. Justice Kekewich, for the appointment of a receiver in the case of Zacharias *v.* the Automobile Association, Limited. Mr. W. C. Kenshaw, Q.C., appeared for the Company. After some discussion an order was agreed to mutually for the appointment of Mr. Taylor as receiver and manager.—*Financial Times.*

Glasgow.—At a recent meeting of the Corporation Mr. Paton stated that the Tramway Committee were already advertising for contractors for some of the tramway extensions that had been sanctioned. The receipts for the week ended July 28 were £8,511. 13s. 10d., as compared with £8,148. 9s. 9d. for the corresponding week of last year.

London County Council Tramways.—No. 17 of the new lines under consideration by the London County Council (see map p. 170, last issue), at Southwark-street, will be especially useful. As in some parts of Stamford-street the carriageway is not wide enough, it will be necessary to widen the street. This line is 1 mile 2 furlongs 7·7 chains long. The estimate of the construction of the line for electrical traction is £45,000.

St. Helens.—At a recent meeting of the St. Helens Corporation Electric Supply and Tramways Committee the starting places and routes to be taken by the full service of electric cars on the entire system were fixed upon. It was also decided that arrangements be made for through cars from Haydock or Parr to Denton's-green and North-road. The committee accepted an offer from the Gas and Lighting Committee to purchase the buildings and fittings of the disused electricity works in the Warrington Old-road for the sum of £1,800.

Dundee.—The Town Council have received their license from the Board of Trade granting the new electric tramways. Ex-Provost Brownlee, convener of the Tramways Committee, said at the last meeting of the Town Council that the electric system had been a great success, and it had worked exceedingly well. The cost of traction was very low. Horse traction had cost them 6d. per car mile, whereas by electric traction the cost had been reduced to less than 1½d. per car mile. There would also be a great saving in the wear of the causeway blocks, and four of the new cars were doing the work of six of the old ones.

Sheffield.—The Tramways Committee have decided to run the Nether Edge, Abbeydale-road, and Eccleshall-road electric cars to the cross-over at the upper side of Fitzalan-square, and thus do away with the block in High-street. They have also decided that the tramline in Church-street, from St. James's-row to the bottom of Bow-street, shall be doubled as soon as possible. The temporary electric car-shed on Queen's road is now completed, and tramlines have been laid to it. Tenders are to be invited for a permanent tramcar depôt to be erected in Queen's-road. The following is a return of the traffic for the month ended July 29: total takings, £9,938. 11s. 6½d.; number of passengers, 2,564,668.

Longton.—At the last meeting of the Improvement Committee the Town Clerk reported that he had been in communication with the Board of Trade with reference to the dispute between the Corporation and the Potteries Electric Traction Company, Limited, which had been referred to arbitration, and he had suggested that all matters in dispute should be decided at the same time, and had received a reply from the Board of Trade that they considered that it would only complicate matters to extend the reference as suggested, and that the fresh points might be referred to the arbitrator after he has decided the present reference. The Borough Surveyor reported that, in accordance with the requirements of the Council, the British Electric Traction Company, Limited, had delivered at the Corporation yard about 800 tons of surplus paving, etc., excavated in the construction of the tramways in the borough.

Wigan.—The borough engineer's report upon the tramway to Markland Mill Bridge states that the construction of the line between Market-street and Markland Mill Bridge was commenced on the 11th of last month at a point about 100 yards west of the Woodhouse Inn, where the first passing place is fixed. The road has been taken up and the site prepared for the rails for a distance of 140 yards double and 270 yards single track. The rails have been laid and completed for a length of 60 yards double and 50 yards single track, and a further length of 220 yards single track is completed with the exception of bonding; 346 square yards of paving has been laid down. The platelayers are at present practically idle in consequence of having to wait for the repunching of the joint-plates, but a supply is expected from Barrow in the course of a day or two. On the whole, satisfactory progress has been made, considering the difficulties with the sole and fish plates. The Electric Light and Tramways Committee have visited the works of Messrs. Dick, Kerr, and Co., Preston, and inspected the work in progress and cars which have been constructed and finished for various corporations.

Derby.—At the quarterly meeting of the Town Council the Tramways Committee reported that the receipts of the Corporation tramways during the four weeks ended July 21, 1900, were £1,345, an increase of £62 as compared with the corresponding period last year. A scheme had been approved by the committee which made a reduction in the number of hours worked by the tram drivers and conductors, but did not alter their pay. The Council was recommended to grant £160 for the purchase of charabancs and two covers. The committee proposed to adopt electric traction for the whole of the routes, and decided to recommend the Council to take powers for the compulsory acquisition of property, situate in Full-street, bounded on the north by the electric lighting station and Silk Mill-lane, on the south by the public baths, on the east by the mill race, and on the west by Full-street, containing an area of about 6,030 square yards, as a site upon which to erect buildings for the generation of electricity. The Council was further recommended to approve the scheme, and to sanction the insertion of clauses in the next Bill in Parliament for alteration of the existing system, for the proposed extensions, for the scheduling of land proposed to be acquired for street widening, and for generating station. After a short discussion the report was adopted.

Dudley.—The Dudley, Sedgley, and Wolverhampton tramway is now practically complete, and will shortly be in full working order. An extraordinary dispute which developed some sensational phases has occurred. In connection with the reconstruction of the local tramways the Dudley Corporation have an agreement with the British Electric Traction Company to take over at valuation in about four years' time the whole of the lines within the borough. The *Midland Counties Express* says: "One clause in the agreement provides that the lines shall be constructed and equipped to the satisfaction of the borough surveyor (Mr. J. Gammage). This agreement has been faithfully carried out with regard to the lines running to Stourbridge, Netherton, and Kingswinford, but in connection with the Sedgley line a serious hitch has occurred. On Saturday it was discovered that instead of laying the cables in earthenware conduits and setting them in pitch, the tramway company's workmen were threading the cables through pipes. Mr. Gammage protested, but the traction company's foreman continued the work in spite of all that could be said. Various official negotiations took place, but still the work proceeded. The upshot was that a gang of Corporation workmen were set to fill up the trench which at Scott's Green the tramway men had excavated. The excitement then became great and rapidly spread. As fast as the tramway men pushed forward their cutting, just as fast the Corporation employés filled it up and battened it down. High words were banded between the two sets of workmen, and threats of a somewhat sanguinary nature were freely indulged in. This continued throughout the evening and into the night. There were on both sides men well known in the town as being very handy with their fists, and a gathering crowd of spectators began to anticipate great doings. Mr. Chief Superintendent Speke, however, took the precaution of drafting to the spot a force of constables. Matters were in no way improved when the tramway company brought carts on the scene to carry away the dirt thrown from the trench, thus taking from the Corporation men the opportunity of refilling the excavation. Our representative called on Mr. Gammage on Sunday to enquire what was the matter. Mr. Gammage briefly explained the situation. Our representative enquired why the matter could not have been left to legal arbitrament, and the surveyor replied that an injunction would be applied for at the earliest possible moment. Meanwhile he had considered it necessary to take other steps."

Blackpool.—A correspondent to our contemporary which rejoices in the short title of *Gazette and News for Blackpool, Fleetwood, Lytham, St. Annes, Poulton, and the Fylde District*, makes some terse and apparently well-deserved remarks with regard to the unsatisfactory working of the trolley arm now in use on the Blackpool cars. He is naturally indignant at having had to spend nearly an hour on a car to get from the Clifton to South Shore, in consequence of the trolley pulley coming off, which had to be replaced no less than 11 times. He considers the present arrangement as quite obsolete, and suggests that Mr. Quin will, no doubt, soon adopt the latest expedient, if he has not already arranged to do so. The letter continues as follows: "There is as much difference between this and the existing primitive and antiquated arrangement as there is between a 'watch and a wheelbarrow' as a chronometer. In order to 'contact' the pulley and wire instantaneously, the fork of the trolley has 'wings' projecting outwards an inch or so, forming with the groove in the pulley a shallow channel to receive and guide the pulley on to the wire the moment it comes under it and is 'let go.' The bamboo imitating boat-hook, now used, is entirely dispensed with, and a thin light rope employed instead. But it has not to be carried up and down the car to be secured out of the way; this is now done automatically. As it is impossible for the trolley pulley to get across, or at right angles to the feed wire, and can be placed in contact the moment it is under the latter, by the car man 'letting go' the end of the rope, when, simultaneously with the contact, the rope is, as just stated, automatically drawn up under the arm, and carried along to the car, the loose end hanging loosely down the side, clear of the passengers and the passing traffic. When the trolley has to be reshipped at the terminus or elsewhere on the journey, the guard simply takes hold of the end of the rope, pulls it down, and by doing so, the simple diminutive 'traveller, as it is designated, which actuates or controls the rope, is drawn up to the end of the arm, close to the trolley, and the pulley of the latter is instantaneously engaged with the conductor wire, as already indicated. The end of the rope is then released, and the 'traveller' immediately gravitates or runs down automatically without friction to a stop-piece or projection on the arm, the end of the rope hanging down, as already stated, ready for the guard to catch hold of it and tranship the trolley again when desired. By adopting this 'wing-trolley' arrangement the traffic would not only be accelerated and the number of journeys augmented, but the profits would also be considerably increased, and the delays and annoyance to passengers reduced accordingly."

LIGHTING AND GENERAL.

Greenock.—The electric light is to be fitted into the dials of the mid-parish clock.

Bangor.—It is expected that the electric light works will be started by the end of this month.

Darlington.—The electric lighting generating station is to be insured for £3,000 for three months.

Dover.—The electric light company intend to extend their main from Castle-street to Victoria-park.

Albury.—The question of electric light will be further discussed at the next meeting of the Parish Council.

Fakenham.—The Parish Council have appointed a committee to report upon an electric lighting scheme.

University College, Liverpool.—The session 1900 1901 commences Oct. 4. Full particulars appear in another column.

Maidenhead.—An enquiry was held on Wednesday into the Council's application for a loan of £25,000 for electric lighting.

Kendal.—We note application is being made for an electric lighting provisional order, and plans, etc., are being prepared.

Stockton.—Extensions of the electric light mains, including the laying of a feeder, at a cost of £1,250, have been agreed to.

St. Albans.—The Board of Guardians have formed a committee to enquire as to the desirability of lighting the workhouse by electricity.

Pwllheli.—The Electricity Committee recently appointed by the Town Council are considering the question of lighting the town by electricity.

Daventry.—The Town Council have decided to renew their application to the Postmaster-General for a post office telephone exchange at Daventry.

Torquay.—The Local Government Board have sanctioned the borrowing of £15,000, repayable in 25 years, for the extension of the electric light works.

Paddington.—It appears that the Vestry disapprove of the step taken by the electric lighting company to enable them to change the voltage from 100 to 200.

Spalding.—The Urban District Council have decided to oppose an application about to be made to the Board of Trade for supplying electric light to Spalding.

Pemberton. — The Electric Lighting Sub-Committee have resolved that plans be lithographed, and that tenders as per plans and specifications be advertised for.

St. George (Hanover-square).—The Vestry have decided to adopt the proposal of the Westminster Electric Supply Corporation in respect to lighting the streets by electricity.

New Branch.—The British Thomson-Houston Company, Limited, have, in addition to the other branch offices, opened a branch at Newcastle-on-Tyne, in the St. Nicholas-chambers, Amen-corner.

Macclesfield.—The Electrical Power Distribution Company intend to apply for a provisional order in the ensuing session for the supply of electrical energy for public and private purposes in the borough.

Explosion.—A number of explosions occurred in the Strand on Saturday, a gas-main and two electric light circuits having become fired. It was only by cutting the connections that the fire was extinguished.

Eccles.—The Town Council are seeking expert advice with a view to the alteration or extension of the existing electric light undertaking so as to supply the probable increased demand during the ensuing winter season.

Leith.—During a recent meeting of the Town Council it was stated that during the last year £404 had been paid for electrical lighting and painting the town hall and another £1,000 towards the electric lighting undertaking.

Electric Cranes.—In order to facilitate landing and embarking mails and baggage on the cross-Channel mail packets, electric cranes are about to be placed on the landing stages at Dover. A great saving of time will thus be effected.

C. V. Lamp Syndicate, Limited.—This Company has been registered with a capital of £14,000 in £1 shares, the object being to manufacture and deal in electric lamps, and to carry on the business of electricians, electric engineers, etc.

Kingston.—The Lighting Committee of the Corporation are urging the Board of Guardians to come to a decision with regard to electrically lighting the workhouse; extensive reports having been prepared, they desire a speedy solution of the question.

A Paris-Berlin Telephone.—The Paris, Frankfort, and Berlin telephone service was opened to the public on Aug. 6. The charge for the use of the wire between Frankfort and Paris is 3s. 4d. and 4s. 10d. between Paris and Berlin for each three minutes.

Hove Electric Lighting Company. — The directors have declared an interim dividend at the rate of 7 per cent. per annum upon the share capital of the Company for the half-year ending June 30 last. The dividend will be paid, as usual, on Oct. 15 next.

Gardner Electric Drill and Hammer Company, Limited. This Company has been registered with a capital of £40,000 in £1 shares, the object being to acquire certain inventions and improvements relating to electric power, rock drills, and electric hammers.

Sevenoaks.—Councillor Marriott has resigned his position as a member of the Electric Lighting Committee, and Councillor Underwood has been elected to take his place, whilst the vacancy occasioned by the resignation of Mr. Ince has been filled by Mr. Crosbie-Hill.

Glasgow.—At Monday's meeting of the Corporation a question as to what progress was being made with the electric lighting of the streets elicited the reply that the delivery of the pillars was being pressed on with, and there was every probability that the streets would be lighted by the time of the exhibition.

Wallsend.—Callender's Cable and Construction Company have made very rapid progress with the erection of the premises required for the distribution of electrical power throughout the important Mid-Tyne township named, and it is probable that the station will be in full working order long before winter.

Digitized by Google

Colne.—A canvass is being made for prospective electric light customers. The Electrical Committee propose to adopt the system of wiring property for electric lighting purposes, if the sanction of the Local Government Board be obtained for the loan.

Burgess Hill.—The Pleasure Grounds, Lighting, and Hackney Carriage Committee have reported to the Urban District Council that at their last meeting a resolution was passed in favour of the instalment of the electric light in the district, and they proposed further considering the subject at a subsequent meeting.

Newcastle-under-Lyme.—A sub-committee has been appointed consisting of the chairman of the Electric Lighting Committee, the Mayor, Aldermen Heath, Mellard, and Briggs, and Councillor Wain to obtain the names and terms of different consulting electrical engineers for an installation of the electric light in the borough.

Salisbury.—It appears that the National Telephone Company have placed without permission a telephone cable in the Market-place. The Council have now decided to inform the company that they could not allow the cable to remain, and have asked them to submit proposals for placing the wires underground before the next meeting.

New Issue.—An issue of fresh capital is being made by the Wycombe Electric Light and Power Company—£5,000 in 1,000 shares of £5 each. The capital, which is needed to meet the expansion of the company's business, is to be issued at a premium of 5s. per share. A dividend of 2½ per cent. was paid on the company's first year of working.

Huntingdon.—The North British Electricity Supply Company intend to apply for a provisional order authorising the company to supply electrical energy for public or private purposes within the area of the borough. The Town Council have decided to consult an engineer with regard to the intended application for an electric lighting provisional order.

Elland —The provisional order for electric lighting for Elland has received the Royal assent, and the chairman of the Council, the chairman of the Electricity Committee, and Councillors Akroyd, Thornton, and Luty have been appointed a sub-committee to enquire for a suitable site for electric lighting and destructor works, and report to the committee.

St. Annes —At the last meeting of the Urban District Council it was reported that sanction had been obtained to erect the works on the new site, north of the gasworks, and that the contractors (Messrs. Moore Bros.) were prepared to carry out the work at the price named for the old site. Messrs. England, Winstanley, and England are engaged to get out the details, etc.

Appointments Vacant.—A working foreman is wanted at once at Sheffield Corporation tramways to take charge of overhead line construction and maintenance. Wages, £2. 10s. per week. Particulars of this vacancy appear in our advertisement columns.—An assistant lecturer and demonstrator is required in the department of electrical engineering at the Croydon Polytechnic.

Stockport —The report of the Gas and Electricity Committee states that the net profit on the past year's working on the electricity department was £118 for the first 16 months. The price of current will be modified by adopting the principle of differential charging, such charge to be at the rate of 5d. per unit for the first hour's daily capacity and 3d. per unit for all current used in excess.

Nantwich.—A letter from Mr. G. R. Peers, of Deansgate, Manchester, electrical engineer, pointing out that as the Council's provisional order to supply electricity to the town had now received the Royal assent this was an opportune time to proceed with the work, and suggesting that he should interview the Council, is before the General Purposes Committee of the Urban District Council.

Stock Exchange.—Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to Babcock and Wilcox, Limited, further issue of 90,000 ordinary shares of £1 each, fully paid, Nos. 440,001 to 530,000, and to allow Edmundson's Electricity Corporation, Limited, further issue of 9,400 ordinary shares of £5 each to be quoted in the official list.

Belfast.—The Council have adopted the minutes of the Electric Committee containing the following resolution: "That a record be made of the committee's appreciation of the able and courteous manner in which Mr. V. A. H. M'Cowen has discharged his duties as chief engineer, which included the designing and establishment of the present electricity works, rendered necessary by the rapid development of the undertaking under his charge."

Personal.—We are informed that Mr. S. H. Short, technical director of the English Electric Manufacturing Company, Limited, who served on both the International Congresses of Electricians at Chicago in 1893 and at Philadelphia in 1884, has been appointed by the Commissioner-General of the Paris Exposition an official delegate of the United States to the International Congress of Electricians which meets at Paris on the 18th of this month.

Barrow.—The concrete for the second boiler foundation is to be carried out now at an estimated cost of £40. A draft of terms and conditions, to be included in an agreement proposed to be entered into with the British Electric Traction Company, Limited, as to the supply of current to the tramways, has been adopted. The electrical engineer has been authorised to prepare specification and obtain quotations for the supply of electric motors for the next 12 months.

Golborne.—At the last monthly meeting of the District Council a communication and formal notice was submitted from the South Lancashire Tramways Company *re* an application proposed to be made to the Local Government Board for a provisional order to supply electricity to local authorities, and the letter asked for an interview. It was resolved that the Council give the representatives of the company an interview on Sept. 6 at five o'clock at the Council offices.

Wrexham.—At the last meeting of the Town Council a letter was read from Mr. Peers, one of the consulting engineers, asking that he might be engaged to prepare a specification for lighting the fire station with electricity, whereupon it was recommended that Mr. Peers be informed that in the opinion of the committee he and his colleague, Mr. Trentham, should submit for adoption by the Depôt Committee and the Council a general specification for the wiring of premises.

London Gazette.—A receiving order has been made out *re* H. Howe, 16, Bold-lane, Derby, on debtor's petition. The first meeting of creditors will be held on Aug. 14 at the official receiver's offices, 44, Full-street, Derby, at 12 noon, and the public examination at Court House, 20, St. Peter's-churchyard, Derby, at 11 a.m. on Sept., 11, 1900.—F. W. Henton, 24, King William-street, Strand, W.C. (G. W. Chapman, Bankruptcy-buildings, Carey-street, W.C.), and L. J. Lawrence, 5, Stafford-street, Old Bond-street, London (G. W. Chapman, Bankruptcy-buildings, Carey-street, W.C.), have been granted their release as trustees.

Publications Received.—We have received from the General Electric Company, Limited, two price-lists for insertion in their big catalogue, one dealing with multipolar motors, and the other with reversible automatic lift controllers and motor-driven starters for presses, rolling-mills, lathes, and tools of all kinds. Also a leaflet dealing with a new curling-iron heater, and other small electrical accessories. From the British Westinghouse Electric and Manufacturing Company, Limited, comes a publication entitled "Polyphase Induction Motors"; while the British Thomson-Houston Company, Limited, sends us a pamphlet describing the magnetic blow-out lightning arresters for direct current of their manufacture. These several publications we hope to accord extended notice in our next issue.

The Telephone as it is in England, A.D. 1900.—The following interesting correspondence has appeared in the *Times*. Mr. James Nelson wrote from the Junior Constitutional Club: "At 12.45 p.m. I called Newport by telephone, giving number, etc., and, after waiting half an hour, rang up asking when I might expect to be put through. I continued doing this until a quarter to three, receiving then the same answer as to every previous enquiry: 'We are asking the Post Office,' but with the addition, 'there are two calls before you!' I then said I did not believe that there could be calls before me as I had been ringing for two hours, and that I should write to the *Times*. This announcement had a surprising result, for in two minutes I was through to my friend at Newport." Mr. W. E. L. Gaine, general manager of the National Telephone Company, wrote from Oxford-court, Cannon-street, on the 8th: "With reference to the letter which appears in the *Times* of to day from Mr. James Nelson, under the above heading, in fairness to the National Telephone Company may I be permitted to say that when messages are sent through the Post Office trunk wires the responsibility for the delays which take place rests entirely with the Post Office and not with the company? Complaints of delays in connection with the trunk wires are received daily from all parts of the country, and are due to the inadequacy in the number of trunk wires to carry the constantly increasing traffic. Unfortunately, the company mostly gets the blame, although it has nothing whatever to do with the matter."

W. T. Henley's Telegraph Works Co.—An extraordinary general meeting of this Company was held at Cannon-street Hotel, E.C., yesterday, when the following resolutions were passed as special resolutions: "(1) That the ordinary share capital of the Company be increased from £150,000 to £200,000 by the creation of 10,000 additional ordinary shares of £5 each, such shares to rank in all respects *pari passu* with the existing ordinary shares, except that dividend shall only be calculated and paid in respect of the amount from time to time paid up thereon; (2) that the Board be and are hereby authorised to offer the said 10,000 new ordinary shares to the holders of the existing ordinary shares, *pro rata*, according to the number of such shares held by them respectively, at such dates, at such price, and on such terms as the Board shall determine, and that the Board be and are hereby authorised to dispose of any of such new ordinary shares which shall not be applied for in accordance with such offer, at such dates, at such price, and on such terms as they shall think most beneficial to the Company; (3) that the preference share capital of the Company be increased from £150,000 to £200,000 by the creation of 10,000 additional preference shares of £5 each, such shares to rank in all respects *pari passu* with the existing preference shares, except that dividend shall only be calculated and paid in respect of the amount from time to time paid up thereon; (4) that the Board be and are hereby authorised to offer the said £10,000 new preference shares to the holders of the existing preference shares, *pro rata*, according to the number of such shares held by them respectively, at such dates, at such price, and on such terms as the Board shall determine, and that the Board be and are hereby authorised to dispose of any of such new preference shares which shall not be applied for in accordance with such offer, at such dates, at such price, and on such terms as they shall think most beneficial to the Company, but it is hereby expressly provided that the Board shall not at any time issue preference shares to an amount exceeding the amount of ordinary shares for the time being issued." Extraordinary general meetings of the preference and ordinary shareholders were afterwards held, when the foregoing resolutions were confirmed.

Digitized by Google

Sutton Coldfield.—A movement is on foot for electrically lighting the borough. The Council are enquiring for sanction to borrow £36,000 for this purpose, together with £600 for street improvements; £26,000 is required for the building of an electric light station, and £10,000 for extensions, if required, to Boldmere, Wylde Green, and Four Oaks. Plans have been submitted giving full details. A large number of applications for electric light are expected, as the gas lighting is bad.

Stafford.—An additional cable is to be laid down on the west side of Gaolgate-street and Market-square from Gaol-square to St. Mary's Churchyard by the Callender Cable and Construction Company, Limited, at 15s. per yard, the total cost being about £300. The committee have decided to increase the salary of the second assistant at the electricity works from £120 to £140, his work having very considerably increased during the 18 months he has been in the service of the Corporation.

St. Pancras.—At the last meeting of the Guardians a report was adopted recommending that the question of providing the main buildings of the workhouse with electric light be postponed; but that the necessary steps be taken for installing the Cook's-terrace Infirmary with electric light, the current to be provided by the electricity department of the Vestry, and the fittings to be obtained and fixed according to a plan and specification already prepared by Mr. Sidney W. Baynes, the chief electrical engineer of the Vestry.

Hampstead.—The Vestry have come to the conclusion that for roads containing many trees arc lamps are not a complete success, but they are now trying the experiment of fitting new electric burners on to some of their present gas standards in the Belsize district. The new lamps are in clusters of three incandescent lights, some of 16-c.p. and others of 32-c.p. So far the result has been most satisfactory; the current is taken from the private supply cables, and the lamps are easily switched on and off by the lamplighters on their rounds.

Bradford.—We gather from the local Press that Messrs. R. W. Blackwell and Co., Limited, of London, who carried out the electrical equipment of the Bradford Corporation tramways to Great Horton and Eccleshill, have addressed a complaint to the Bradford Corporation. They allege that in connection with the extensions now in hand (for which their tender was £13,540), the successful contractors, Messrs. McCartney, Elroy, and Co. (whose tender was £12,064), have been allowed detailed deviations from the specifications, which amount to a saving of £851.

Winchester.—At a recent meeting of the City Council Sanitary Committee, Messrs. Lankester and Son submitted full particulars of their estimate for lighting the pumping station by electricity. The capital of the wiring plant and instruments is estimated at £269. Interest and depreciation, coal, oil, and repairs would amount to £32 per annum. The committee recommended that the tender be accepted, and the work forthwith carried out by Messrs. Lankester, and that application be made to the Local Government Board for sanction to borrow £275, repayable in 20 years.

Salford.—At a recent meeting of the Town Council, Councillor Foden asked if the Lighting Committee had decided upon the method of lighting by means of the new tramway poles, and whether there would be any improvement in the "twinkle, twinkle, little star" light they had in Cross-lane? Councillor Hulton said that the Electric Light Committee were ready to proceed as soon as they could get the current, and as soon as the Tramways Committee had finished their work. It was intended to put an arc lamp on every alternate pole, and the other poles would also be lighted.

Grantham.—The Town Council have adopted the following report with regard to the proposed municipal telephone scheme: "That the powers granted under the telephone license from the Postmaster-General to the borough of Grantham be put in force subject to the Council's consideration of General Webber's detailed reports and estimates, which he is hereby requested to submit; and that these reports and estimates be referred to a committee consisting of Councillors Parker, Coultas, Linnell, and Rowle, with a direction to report to the Council as soon as possible with detailed and definite recommendations."

Shipley.—Colonel Coke has held an enquiry into the application of the District Council for sanction to borrow £22,000 for the purpose of furthering the Council's electric lighting scheme. It was stated that there had been application by various tradesmen and business firms in the town for 2 500 incandescent and 49 arc lamps. One and a half miles of tramway in the Shipley district, owned by the District Council, would be worked by electricity at the expiration of the Bradford Tramway Company's lease in 1903, and Shipley would then supply the current for their own district. Mr. R. C. Quin, the consulting engineer to the Council, estimated that the annual income for the works would be £3,088, and the expenditure, including £1,553 for interest and sinking fund, would be £2,044.

Hull.—The City Council have adopted a report of the Electric Lighting Committee with regard to Messrs. Earle's contract for the two dynamos, stating that Mr. Payne, of Messrs. Payne, Galloway, and Payne, solicitors for the Vulcan Boiler Insurance Company, sureties for Messrs. Earle, suggested that the Corporation should agree to Messrs. Thomas Parker, Limited, supplying the dynamos, but without a spare armature, the Corporation paying for such dynamos the sum of £3,725 (the same amount as would be payable under Earle's contract), and his clients (the sureties) would pay the difference between that sum and the price charged by Messrs. Thomas Parker, Limited, which would amount to between £400 and £500. The committee recommended the Council to sanction this course.

Whitechapel.—The Board of Works have decided to borrow £30,500 on account of £105,170 for the purpose of carrying out a portion of the electric light installation. Another sum of £20,000 is to be borrowed in respect to the same work. Mr. J. Hartis, J.P., the chairman of the Whitechapel District Board of Works, last week opened the new dust destructor, and laid the foundation stone of the new electricity supply station. When completed, these works will have cost the large sum of £105,000. The present installation, which includes over 40 miles of cables, was laid down within 11 months from the time the specifications were drawn up and tenders accepted for the work. The Board is now generating the current for 60 arc street lamps, and making arrangements for 35 more, and is supplying 8,054 8-c.p. lamps to private consumers, while applications for 958 additional lamps have been received. Already over £1,000 has been paid by consumers.

Gloucester.—The accountant of the City Council has laid before the Electrical Supply Committee a statement of accounts, which showed that the amount of the loan already authorised was £43,450, of which £10,000 had been borrowed at 2¾ per cent. The total expenditure amounted to £30 772. 8s. 9d., including £6,141. 1s. on buildings, £7,198. 2s. 9d. machinery, £1,000 accumulators at stations, £12,279. 2s. 7d. mains and laying, £1,072. 13s. 8d. meters, £800. 15s. 6d. electrical instruments, etc., £1,495. 12s. 9d. engineer's commission, etc., £496. 7s. 11d. general expenses, and £285. 12s. 7d. cost of the provisional order. The descriptive pamphlet of the work is estimated to cost £38. The committee have instructed the town clerk to record upon the minutes the fact that the electricity works were formally opened by the Mayor on July 19 in the presence of the members of the Corporation and a large number of citizens, when general satisfaction was expressed with the installation and the public lighting. It has been resolved that the engineer and surveyor be instructed to prepare and submit for consideration at the next meeting a scheme for extending the arc lighting in the principal streets of the city.

Tunbridge Wells.—In view of doing away with the nuisance now caused by the smoke emitted from the shaft at the electric lighting works and the noise and vibration caused by the working of the electrical plant, the Council have decided (1) to at once proceed to erect an additional chimney at an estimated cost of £3,500, and to obtain tenders for the execution of the work, which is to be carried out under the superintendence of Mr. Maxwell, A.M.I.C.E., the borough surveyor; (2) to provide a new flue and economiser (estimated to cost £1 000), which are rendered necessary by the erection of the new chimney; (3) to call upon Messrs. Ferranti to forthwith put the large engine recently supplied by them into good working order according to their contract; (4) to authorise the committee to consult Sir William Preece, if necessary, from time to time during the progress and upon the completion of the works and to obtain a further report or reports from him; (5) to instruct the town clerk to apply to the Local Government Board for sanction to the borrowing of £5,000 to provide for the estimated cost of the works as follows: chimney, £3 500; economisers and flues, £1,000; contingencies, £500—total, £5,000.

Beckenham.—At a recent meeting of the Electric Lighting Committee the Surveyor reported that he had examined the tenders for free wiring sent in at the last meeting of the Council, and after consultation with the electrical engineer and the clerk he brought up a model tender giving average (and identical for each system of wiring) prices agreed to by each of the three lowest tenderers for each kind of wiring specified, and recommended such model tender for acceptance. This proposal, which has been confirmed by the Council, means that all work will be carried out on the same specification and paid for at the same price, and ratepayers will have the choice of three firms in ordering their work. An arrangement with the British Insulated Wire Company for the supply of plain lamps and fittings has also been approved. The Public Works Loan Commissioners have informed the Council that they are unable, for want of funds, to entertain their application for a loan for wiring. The surveyor recently was authorised to invite tenders for fencing the electric lighting station and depot, and has submitted the following tenders received for fencing the electric light works: Mr. Jones, £203. 7s.; Mr. Nightingale, £197. 10s. 6d.

Electric Power Scheme.—A correspondent writes to the *Glasgow Herald*: "Sir William Preece, the eminent electrical engineer, and Messrs. Strain and Robertson, civil engineers, Glasgow, have during the past week been visiting various industrial centres in the West of Scotland in connection with a project for establishing on or near the coalfields great central stations for generating electrical energy on a large and economical scale. The objects of the scheme are to make these central stations of such a size, and to establish them in such situations, as to enable the energy to be generated at the lowest possible cost, and distributed without serious loss to the whole of the district to be supplied. The scheme, which has been under consideration for a considerable time, and has been carefully matured, is a comprehensive one, and includes large districts in the counties of Lanarkshire, Ayrshire, Renfrewshire, Stirlingshire, and Dumbartonshire. The promoters of the scheme propose to supply the electrical energy in bulk for power, traction, and lighting purposes to corporations and county councils, and other large consumers. The agents for the promoters are Messrs. Wright, Johnston, Mackenzie, and Roxburgh, solicitors, Glasgow."

Aldershot.—The Power and Traction Company have asked the Council that their decision might be left over till their offer had been received, as the scheme is a comprehensive one. Edmundson's Electricity Corporation made what was called a sporting

Digitized by Google

offer. They suggested that the Council should arrange the necessary loan for carrying out the works. The company would undertake to carry out the works under the supervision of the Council and at prices to be arranged. Further, the company would undertake to manage the works for seven years, taking all profit or loss that might be made, and guaranteeing to the Council the payment of the amount of the interest and sinking fund which would be due upon their loan. The Council would have the option of taking over the works at the end of the seven years by paying the company a premium of 15 per cent. upon the capital expended, or, if they preferred to do so, to allow the company to continue the management for another seven years, the premium to be paid at the end of that time being 10 per cent. By this method the Council would avoid all risk, and would be free to take over the works at a period when there would be no question as to their satisfactory financial position. No final decision has, however, been arrived at.

Portsmouth.—Mr. Price (the electric light superintendent) has submitted to his committee a report showing the extension of the electric lighting in the borough, and forecasting the demand that would have to be met during the Christmas season of 1901. The *Hampshire Telegraph* says that Mr. Price estimated that the probable demand would be for 53 per cent. of the lamps on at once, making a total of 1,437 kw., or allowing 150 kw. for the arc lamps, a maximum demand for the winter of 1,587. The existing plant gives a total output of 2 086 kw., of which one quarter must be allowed for contingencies, so that the existing plant would be able to meet the demand for the coming winter. Assuming, however, that the same number of lamp connections would be made in 1901, the maximum demand at Christmas, 1901, would be 1,853 kw., allowing for no increase in the arc load, and it was, therefore, said Mr. Price, necessary to increase the plant capacity by 500 kw., which, allowing for spare current, would give 1,939 kw. to meet a demand of 1,853 kw. The committee had received from Messrs. Parsons and Co., of Newcastle, who built the present turbine engine, which has not proved a success, an offer to allow the committee the amount paid for it if they will give an order for Christmas twelvemonth for a 500-kw. machine of the latest pattern. The machine is practically of the same character as the turbines of H.M.S. "Viper," and four of them were seen in operation at the Metropolitan Electric Light Supply works on Tuesday by the Mayor (Mr. H. R. Pink), and the chairman (Alderman G. Ellis), and other members of the committee. The engine is said to be an economical one. It would require no foundations, and would occupy about one-fourth of the space in the engine-house required by the present style of engine. The price would be £5,360. The committee decided to recommend the Council to authorise them to accept this offer and order one of the new turbines for Christmas, 1901.

Rotherham.—This town is in the unique position of developing its gasworks contemporaneously with the inauguration of an electric light station, the latter being also required for traction, in which enterprise the Council intends being up to date. Some two years ago the Corporation obtained an electric lighting provisional order, and shortly afterwards called in Prof. Kennedy to advise. They adopted his report in January, 1899, and appointed him as engineer for the work. Part of the "Phœnix Land" was purchased at a cost of £2,664, and there was expended upon it £305 in roadmaking. Contracts were entered into for boilers, engines, dynamos, batteries, switchboards, cables, etc., amounting in all to £15,138. 1s. 8d., and in March last the Corporation applied for and have since received the sanction of the Local Government Board to borrow £27,969 for the purpose of electric lighting. The electric lighting scheme provides for both private and public (arc) lighting under the three-wire continuous-current system. There will be about 35 public lamps. Provision is also being made for the generating of power for the electrical tramway system at the same station. The buildings of which the foundation stone was laid comprise engine and dynamo house, boiler-house, battery-room, engineers' offices and stores, and workmen's room, together with coal bunkers, chimney stack, and economiser, and the necessary smoke flues, water lodge, etc. Every provision is being made for further extensions. The chimney stack will be 160ft. high, with square panelled base diminishing to an octagon shaft, the top portion will be panelled and finished with a 10ft. deep buff terra-cotta moulded cap, the internal dimension of the stack being 8ft. 9in. The water lodge is of puddle and concrete, and will have a capacity of 220,000 gallons. The site will be enclosed by a boundary wall, and the portion front of the building finished with palisading. On the 1st inst. the Mayor (Councillor G. Gummer, J.P.), laid the foundation stone of the works.

Colchester.—In view of the military premises being lighted electrically by the Town Council, the Electric Light Works Committee at the last meeting of the former presented a report upon the negotiations embodying a letter in which they offered to light the new barracks at 4½d. per unit for the first 50,000 units taken in any year, and 4d. per unit for any quantity over that amount. The committee recommended that the current to be supplied to the new premises should be at a pressure of 210 volts, the recommendation being made on several grounds, the most important being that if the supply be at the higher pressure the cost of the cable will be reduced by 75 per cent. The main which was laid for supplying the hospital would not be sufficient for conveying the electricity required for the new premises, and it would therefore be requisite to lay an additional cable, which the War Department had agreed shall be laid in the most direct possible route across the Abbey Field, and which would be connected to the existing cable so as to form what is called a "ring," or continuous cable. The additional lamps which would probably be lighted are expected to equal 1,200 8-c.p. lamps, and the revenue in any one year, if 50,000 units be consumed, will amount to £937. 10s. The committee, being fully satisfied that the additional revenue which will be derived in respect of the supply to the new premises justifies their proposals, recommend the Council: (1) to enter into an agreement for supplying electricity for lighting throughout (*a*) the military hospital; (*b*) the whole of the Goojerat Barracks, with the double canteen and married quarters; and (*c*) the officers' mess and recreation rooms in the Sobraon Barracks at the following specified charges: for the first 50 000 Board of Trade units taken in any year, 4½d. per unit; for any quantity taken in any year over 50,000 Board of Trade units, 4d. per unit. The agreement to be for a fixed period of seven years. (2) To empower the committee to obtain and lay a new main over the Abbey Field in the position approved by the War Department, the estimated cost of the main being £1,500; the cost of the main to be included in the next application for a loan. (3) To empower the committee to have executed at the military hospital, as required by the War Department, certain works, renewals, repairs, etc., for adapting the installation thereat to receive electricity at a pressure of 210 volts. After a slight discussion the report was adopted.

Parliament.—During the past week, in the House of Lords, the following Bills were read a third time: Plymouth, Stonehouse, and Devonport Tramways, North Metropolitan Electric Power Supply, Southport and Lytham Tramroad, Huddersfield Corporation Tramways, London County Tramways (No. 1), London County Council (Improvement), London County Council (General Powers), and London United Tramways. In the House of Commons the following Bills were read a third time: Manchester Corporation Tramways and Bexhill and Rotherfield Railway. The following Bills have received the Royal assent: London (Clerkenwell and Holborn) Provisional Order, London (Poplar) Provisional Order, Kingscourt, Keady, and Armagh Railway, Manchester Corporation Tramways, London (St. Marylebone) Provisional Order, Walsall Corporation, Liverpool Overhead Railway, St. David's Railway (Abandonment), Costa Rica Railway Company, Limited, Blackpool, St. Annes, and Lytham Tramways, Buenos Ayres and Rosario Railway, Ipswich Corporation Tramways, Salford Corporation, Withington Urban District Council, Sheffield Corporation, Clontarf Urban District Council, Baker-street and Waterloo Railway, Bradford Corporation, Charing Cross and Strand Electricity Supply, City of London (Various Powers), Croydon Tramways and Improvements, Durham (County of) Electric Power Supply, Exeter Corporation, Farnworth Urban District Council, Halifax Corporation, Lancashire Electric Power, Lancaster Corporation, Liverpool Corporation, London County Tramways (No. 2), Newcastle-upon-Tyne Electric Supply, Oldham Corporation, South Lancashire Tramways, West Bromwich Corporation, West Ham Corporation, Margate Corporation, Sunderland Corporation Bournemouth Corporation, Bexhill and Rotherfield Railway, Workington Railways and Docks, London County Council (Improvements), London County Council (General Powers), London United Tramways, Rochdale Corporation, Dublin Corporation, Plymouth, Stonehouse, and Devonport Tramways, North Metropolitan Electric Power Supply, Southport and Lytham Tramroad, Huddersfield Corporation Tramways, London County Tramways (No. 1), Devonport Corporation, Hastings Corporation, Scarborough Corporation, Newry, Keady, and Tynan Light Railway, Christchurch and Bournemouth Tramways, Metropolitan District Railway, Coventry Corporation, Taunton Corporation, South Wales Electrical Power Distribution, Tottenham Urban District Council, Southport Corporation, and Morley Corporation, and the Tramways (Ireland) Amendment Acts. Mr. Seale Hayne's Select Committee of the House of Commons has passed the preamble of the Bill confirming the provisional order granted by the Board of Trade to the Corporation of Batley, authorising the construction of tramways within the borough of Batley to be worked by electricity on the overhead trolley system, and the borrowing of £51,000 for the purposes of the order. The Earl of Camperdown's Select Committee of the House of Lords has passed the preamble of the Bill to confirm, *inter alia*, the provisional orders granted to the vestries of Mile End Old Town, Limehouse, and St. George's-in-the-East enabling them to supply electricity in these districts.

COMPANIES' MEETINGS AND REPORTS.

CENTRAL LONDON RAILWAY.

The tenth ordinary general meeting of this Company was held on Wednesday at the Holborn Restaurant, Sir Henry Oakley presiding.

The **Chairman** congratulated the stockholders on the successful completion of the railway, which was opened on July 30. Up to the present there was every indication that their most sanguine estimates of the utility and popularity of the line with the public would be realised. The Company had spent during the half year a sum of £185,000, which was much less than they had spent in corresponding periods in other years, which was owing to the fact that the works in connection with the stations and the electric plant did not absorb so much money as was expected. As regarded capital expenditure, without committing themselves to a final statement, but having carefully gone into the estimates of the work to be done and paid for, the Board had every reason to believe that the whole undertaking would be completed for the

Digitized by Google

original capital, and unless the business was so extended as to render further large capital expenditure necessary the Board would not require any authority from the shareholders at present to raise new capital. They had commenced to work the line with a five minutes' service, and had established a general fare of 2d. for any distance. He was glad to say that from the time of opening the line had been a great success. The first train that was run was crowded, and they had remained so ever since, the mid-day trains being also very well filled. The total number of passengers carried on the first day that the line was opened was 85,400, on Bank Holiday the number was 100,391, while on the day previous to the meeting the number had grown to 105,171. There was, therefore, absolutely no reason to doubt that the public were pleased with the service.

Lord Rathmore seconded the adoption of the report.

A **Shareholder** said that he regarded the 2d. fare as too small. He thought many people would prefer to a pay a little more and get a seat than to pay 2d. and not get one. He also proposed the division of the fare into smaller ones.

The **Chairman**, in reply, said the Board had not adopted the 2d. fare without the closest investigation of all matters. They had sent twice to America to examine into the working of the average fare system, and decided on that as the most workable on their railway. The 2d. fare had been decided on after considering the average fare of the City and South London Railway, the Liverpool Overhead, the Metropolitan and the District Railways, and the London Road Car Company. The Board were at present quite satisfied with the position of affairs.

The report was adopted.

METROPOLITAN DISTRICT RAILWAY.

On the 2nd inst., under the presidency of Mr. J. S. Forbes, the half-yearly meeting of the joint Company was held at the Westminster Palace Hotel.

The **Chairman** said that the receipts showed a small increase, but in the working expenses there had been a rather considerable increase, so that the profit was diminished, with the consequence that there was a slight diminution in the dividend.

In reply to a question, the following was elicited from Mr. Forbes: It had been proposed to deal with the question of the use of electricity as a separate matter, but he might at once state that the result of the experiment conducted under the direction of Sir John Wolfe Barry and Sir W. H. Preece had been favourable. In view of the heavy expenditure which the introduction of electricity might involve, they had thought it best to consult the best authorities, and working a mile by electric traction they had established the fact that electrical traction could pull a heavier load than the ordinary locomotive, and also that it could pull it quicker. What the directors proposed to do immediately was to extend that mile to Putney, or some other outlying portion of the system, where they could work it themselves without having to consult anyone else. Both the Metropolitan and District Companies were anxious to bring about the great object in view in connection with this question, and that was to make the Inner Circle an electrically-worked railway. They hoped in a short time to receive tenders from people capable of carrying out the work, three objects in view being economy, purity of the atmosphere, and capacity for carrying more weight.

A dividend was declared at the rate of 3⅛ per cent. per annum on the preference stock.

NATIONAL ELECTRIC SUPPLY.

An extraordinary general meeting was held at the Company's offices, Preston, on Monday.

Mr. John Booth presided, and the following resolution was carried: "That the capital of the Company be increased to £184,943 15s. by the creation of 20,000 new shares of £5 each, to be numbered 9,051 to 29,050 inclusive, such shares to be *pari passu* with the preference shares numbered 1 to 9,050, issued or to be issued under or by virtue of the special resolution of the Company passed on Sept. 21, and confirmed on Oct. 7, 1898, and to be preferential (as to the amount paid up thereon) to the ordinary shares both as to payment of dividend and capital, and that such shares or any of them may be issued at any time, or from time to time, at the discretion of the directors, and either at par or at a premium, and that such shares shall not confer any right of voting at a general meeting of the Company."

BRITISH ELECTRIC TRANSFORMER MANUFACTURING.

The second ordinary general meeting was held on Friday last at Faraday House, Charing Cross-road, Mr. R. Stewart Bain presiding.

The **Chairman**, who expressed himself satisfied with the last year's transactions, said the turnover had been £24,043, as compared with £12,614 for 1898-99, which was their first working year. The manufacturing charges had been £13,448, which was equal to about 56 per cent. of the turnover, against 81 per cent. in the preceding year, while the general charges in both years had been, approximately, 10 per cent. of the turnover. After deducting all charges a profit remained of £6,184. The directors had succeeded in obtaining letters patent in Germany for the transformers, which were also covered by letters patent in France, Belgium, Italy, Austria, Switzerland, the United States, New South Wales, South Australia, Western Australia, Queensland, and Tasmania. Their transformers were being exhibited at the Paris Exhibition, which entitled the Company to add an additional six months to the time within which they must work the patent in France. The vendors' shares did not rank for dividend until the subscribed shares had received 10 per cent. for one complete year. As it was now proposed to recommend that a dividend of 10 per cent. should be paid, the 20,000 vendors' shares would rank *pari passu* with the subscribed shares as from the 1st ult. Negotiations were in progress for the purchase of freehold land on which to erect new works, and the Board expected to be able to pay for it and erect and equip the works without increasing the capital.

The report, the payment of a dividend at the rate of 10 per cent. per annum on the subscribed capital, together with a bonus at the rate of 2½ per cent. for the year, and the transfer of £2,500 to reserve fund, were carried.

PAISLEY TRAMWAYS.

The thirtieth ordinary general meeting of the shareholders of the Paisley Tramways Company was held last week at the registered office of the Company.

Mr. J. G. Stewart, who presided, said, compared with last year, the revenue had decreased by £203. 16s. 8½d., while the expenditure had increased by £67. 14s. 1½d. They had been called on by the authorities of Paisley to expend a considerable sum on repairing the lines. That had been done and the accounts were paid, and he was bound to say the lines were in a more satisfactory condition now than they had been in for a long time. When the time came for transference that would tell in their favour, and they would get the money back—at least, he hoped so. In 1902 the Paisley Corporation would no doubt take advantage of the powers conferred on them and take over the system. If they did not, then the Company must work away and do their best for another period.

Mr. J. F. Baird seconded the adoption of the report, which was passed.

CHILI TELEPHONE.

The report of the directors of this Company for the year ended March 31, 1900, states that the aggregate number of subscribers at all centres at the end of the year was 4,613, as compared with 4,486 at the beginning, or a gain of 127 for the year. The gross revenue in Chili from all sources was: in 1899-1900, 651,436dol.; in 1898-1899, 599,994dol.—an increase of 51,442dol. The expenditure in Chili was: in 1899-1900, 364,549dol.; in 1898-1899, 375,230dol.—a decrease of 10,681dol. The net income in Chili from all sources was: in 1899-1900, 286,887dol.; in 1898-1899, 224,764dol.—an increase of 62,123dol. The average rate of exchange for the year was 15·17d., as compared with 14·27d. in the previous year, giving an increase for the year of 0·90d. Converted into sterling at these rates, the figures are: in 1899-1900, £18,130; in 1898-1899, £13,366—an increase of £4,764. The liquid assets and liabilities in Chili on March 31, 1900, were valued at 16½d., the current rate of exchange on that day, as compared with 14½d., at which they were valued on the corresponding date of the previous year. The increase in the value of the liquid assets over liabilities in Chili, due to this rise in exchange, amounts to £1,755, which has been carried to reserve. The balance to the credit of the revenue account, including £448 brought from the previous year, is £12,847, of which £3,044 has been carried to reserve for depreciation and renewals. The directors recommend the payment of a dividend of 4s. per share, free of income tax, being at the rate of 4 per cent. per annum, absorbing £8,800, and leaving a balance of £1,003 to be carried forward. During the year the capital outlay in sterling was £1,798, and the total mileage was: on March 31, 1900, 8,298 miles 990 yards; on March 31, 1899, 8,065 miles 513 yards—an increase of 233 miles 477 yards. In accordance with the articles of association, Mr. George Keith retires from the Board of directors, and, being eligible, offers himself for re-election. The auditor, Mr. Thomas A. Welton, also retires, and offers himself for re-election.

YORK TRAMWAYS.

The report to be submitted to the shareholders at the half-yearly ordinary general meeting at York on Sept. 6 states that the gross receipts for the half-year ended June 30 amounted to £2,148. 18s. 5d., and the working and general expenses to £1,621. 0s. 7d., showing a balance of £527. 7s. 10d., which it is proposed to appropriate as follows: interest on 5 per cent. debenture stock (less income tax), £145; dividend at the rate of 6 per cent. per annum (free of income tax) on share capital, £266. 5s.; balance carried to reserve fund for renewals and contingencies (bringing the fund up to £1,227. 5s. 7d.), £116. 2s. 10d. The number of passengers carried during the half-year has been 847,969. The York City Council has applied to the Board of Trade for power to acquire by purchase so much of the tramways within the city as are authorised by the York Tramway Order, 1879, together with the necessary equipment for working. The directors recommend that the dividend be paid on Sept. 7.

SMITHFIELD MARKETS ELECTRIC.

A circular has been issued by the directors stating that the business of the Company is progressing satisfactorily. Since the commencement of the year the lamps connected have steadily increased, while within the past few weeks 30 new installations

Digitized by Google

have been obtained in the Central Markets. The number of units sold for the half-year amounted to 367,306, against 174,827 for the corresponding six months in 1899. The directors feel justified in hoping that the result of the current year's working will show a substantial improvement upon the previous year, notwithstanding the high price of coal and the probability of still further advances.

PROVISIONAL PATENTS, 1900.

JULY 30.

13636. Combined electric alarm switch and air-brake coupling. William Edward Cocks, 11, Queen's-road, Peckham, London.

13639. An improved electric motor. Arthur George Bloxam, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (La Société Ch. Mildé Fils et Cie., France.)

13643. Improvements in wireless telegraphy. Charles Maréchal, Jules Michel, and Eugène Dervin, 78, Fleet-street, London. (Complete specification.)

13652. Improvements in and in the construction of electrodes. Robert Jacob Gülcher, 322, High Holborn, London.

13656. Improvements in and relating to the electrodes of accumulators and the manufacture thereof. Reginald William James, 1, Queen Victoria-street, London. (Jean Jacques Heilmann, France.)

13661. Improvements in tramcars, railway cars, or locomotives, and the like driven by electric or other motors. William Robert Renshaw, 24, Southampton-buildings, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on August 25.

1899.

16055. Electric switches. Jones.

16824. Apparatus for electro-chemical and electro-thermic melting operations, especially for the production of calcium carbide. Grauer.

19856. Magnetic separators. Clark. (Courtney.)

24514. Electricity meters. Boult. (Saldana.)

1900.

2702. Electromagnetic brake dynamometer. Rieter.

5257. Apparatus for winding or producing coils, bobbins, helices, or the like for electrical and other purposes. Heys. (Scott Varley and Anderson.)

8671. Construction of electric switch Schulz.

8880. Means for recording the number and duration of telephonic conversations. Eichwede.

9836. Conduits of electric railways. Larkin.

9879. Electric incandescent lamps. Krayn.

10181. Means for electrically generating steam. Griffing.

10357. Electrical apparatus for surgical and other purposes. Hynes and Randall.

10579. Electrically-controlled apparatus for shifting and locking railway points and signals. Siemens Bros. and Co., Limited. (Siemens und Halske Aktiengesellschaft.)

12016. Electrically-propelled motor road vehicles. Ryan.

12111. Electrical jacquards and dobbies. Szczepanik and Kleinberg.

NOTES.

The New German Cable.—According to Reuter, the shore end of the new German Transatlantic cable was laid on the 11th inst. from Coney Island. The cable-ship "Anglia" will continue laying the cable as far as the Azores.

Parisian Tramways.—We learn that a concession has been granted to the Compagnie des Tramways Mecaniques to construct five new lines from the suburbs of Paris into the town. The tramways are to be operated by three-phase current at high tension. The general application of electric traction on the Paris tramways should greatly develop the traffic, and is expected to greatly reduce the cost of running.

A New Application.—The uses to which electrical energy is put are multiplying rapidly as the economy and convenience of its transmission become better established. As in many other places where great works, etc., are in course of construction, electricity seems to be playing an important part in connection with the National Harbour at Dover. We note that electrically-driven concrete mixers are now employed for making the 40-ton foundation blocks used in the deep-sea work.

Storage Batteries.—At the meeting of the North-Western Electrical Association, Mr. Ferguson read a paper on "Storage Batteries for Small Stations." Among other things, he stated that a storage battery operated under favourable conditions would show upon test an energy efficiency of 75 per cent. and an ampere-hour efficiency of 90 per cent. The yearly energy efficiency of a storage battery operated under ordinary central-station conditions would, in all probability, not exceed 65 per cent.

Electric Brakes.—A State Railroad Commission in America has been reporting upon the comparative value of brakes, and it had under trial 25 varieties. Their conclusion upon the whole matter is that the electric brake stood first in the tests, the friction brake next, a hand-power brake third, and air brakes fourth. They suggest that, except in special cases where the liability to accident is very remote, the ordinary hand brakes now generally used should be replaced by a better system.

Budapest.—A short length of railway track has been put down and equipped for electric traction near Budapest by Messrs. Ganz and Co. The line is to serve for experimental purposes in connection with the introduction of electric traction for main-line work into Northern Italy which has been entrusted to the above firm, as previously noted in these columns. The current for working the line is transmitted at a pressure of 20,000 volts in the primary leads, and subsequently transformed down to 3,000 volts in the secondary.

Voltage.—The constantly-recurring question of voltage is not likely to receive a definite answer within a short period of time. A good many engineers hold the view that a very much higher voltage should be permissible everywhere, and argue that if this was so, the chapter of accidents would probably be short. There is much to be said from this point of view, in that everyone would then strive at all hazards to keep from all possible contact, and jerry-made apparatus would soon become a thing of the past, in that it would be unsafe.

Vienna-London Telegraphic Facilities.—Though the Vienna Chamber of Commerce have petitioned for better telegraphic facilities between that town and London, the authorities concerned seem to consider the existing facilities quite sufficient. The difficulties experienced lately in transmitting messages between the two capitals are not denied, but, at the same time, an alternative route is pointed out which would appear to have been left out of consideration—namely, that *vid* Zurich and Paris—to which will be soon added the Cologne-Emden connection.

Coherers.—In a paper read before the Physical Society of Frankfort-on-the-Maine, Herr Schafer described a "coherer" designed for use in connection with wireless telegraphy. The coherer is made by pasting strips of tinfoil on a glass plate. If the glass be silvered, it will answer the purpose equally well provided the silvering be divided into strips by a knife. A current of electricity across the metallic strips gave an electric resistance of 50, but when the electric waves impinged on them the resistance was increased a hundredfold. The coherer works in a vacuum.

The Wannsee Railway.—The adaptability of electricity for main-line working is receiving a practical test in Germany. The latest example of the application of electricity for this purpose is to be found in the Wannsee Railway between Berlin and Zehlendorf, which has been equipped for electric traction by Messrs. Siemens and Halske, the new service of trains having been recently inaugurated. For the present there will be only six electrically-propelled trains on the system, the service of steam-driven trains formerly employed being retained. A mixed system of working must, therefore, be in operation, particulars of which are promised by the *Elektrotechnische Zeitschrift* for an early date.

Electricity and the Textile Industry.—The great advantages attending the separate driving of looms are becoming more and more recognised in Austria, where many large mills have already been equipped with electrical generating and motor plant. One of the latest installations of the kind is that which Messrs. Herm. Schuk and Co. have put down in their new silk-weaving mills at Rovereto, South Tyrol, where a polyphase plant has been installed for driving, at present, 400 looms. The separate driving of velvet-weaving looms by means of electric motors is also stated to have been found completely satisfactory after severe practical tests, notwithstanding the difficulties presented.

Polyphase Work.—The well-known firm, Messrs. Lahmeyer and Co., of Frankfort-on-the-Maine, have just completed an interesting polyphase transmission scheme in Sinaia, the summer seat of the King of Roumania. The prime power for driving the generators is furnished by the water of the River Prahova. One of the principal objects of the installation is to provide the industrial quarters of the Prahova Valley with cheap energy, which will be transmitted distances up to 45 km. from the generating source. A large demand for current has arisen in the extensive petroleum fields in the neighbourhood. The primary polyphase current is transmitted to the various centres of distribution at a tension of 11,000 volts.

A Useful Directory.—We have received a copy of the "Universal Directory of Railway Officials" for 1900 from the Directory Publishing Company, Limited, 8, Catherine-street, Strand, W.C. The volume, which is now in its sixth year of publication, has been carefully revised and brought up to date. Practically all the tramways worked by mechanical means in the United Kingdom are now included, which feature should render the directory of considerable use to the electrical industry. Some difficulty, we understand, has been found in obtaining accurate information relative to the railways of the Transvaal and the Orange River Colony owing to the war in South Africa, but that detracts but little from the general usefulness of the directory.

Digitized by Google

Utilising the Waves.—An ingenious substitute for the old bell and gas buoys that mark the dangerous parts of our coasts is reported to have been subjected to severe tests by the Trinity House authorities with satisfactory results. The new type of buoy is said to be similar in appearance to the old, but, instead of relying upon oil or gas for its illuminating power, is equipped internally with a small electrical generating plant, which is driven by a piston actuated by the movement of the waves, being automatic in action, however slight this motion. The electricity generated supplies a powerful flashing or fixed light, as required, or works an apparatus for sounding blasts on a syren. This seems all very nice, but we should like to examine the apparatus ourselves before venturing to express an opinion upon its practical value.

Italian Railways and Electric Traction.—The commission deputed by the Italian Government to study the problem of the application of electricity to the railways, has reported that it is unable to give a decision on the subject until after a trial of four systems. These are: first, electric traction with accumulator vehicles with the Planté type of plates; secondly, vehicles with the Pescetto type of accumulator; thirdly, with overhead wires and high-tension three-phase current; and, lastly, the third-rail system with continuous current. The first system has already been tried on the Milan-to-Monza line, the second will next be tried on the line from Bologna to San Felice, the third will be experimented with on the Lecco-to-Colino line, and the fourth on the Milan-to-Port Ceresio. In this way the commission hopes to obtain a fair idea of the relative merits of each system, and to give a just decision as to the best.

The Rontgen Society.—From the third annual report of the Röntgen Society it appears there has been a very satisfactory increase to the membership of the society during the year. An addition of 62 new ordinary members, many of them residing in distant parts of the British Islands, and not a few in the Colonies, is sufficient evidence of appreciation of the society's work, and more especially of the value of its published *Transactions* in the *Archives*, as the report points out. The council has recently arranged that the *Archives* shall in future be issued bi-monthly during the session of the society in January, March, May, and July, so that members shall be in possession of papers read at the meetings without unnecessary delay. It may also be mentioned that Dr. J. B. Macintyre, of Glasgow, one of the earliest and most prominent of practical X-ray workers, has been nominated as the next president of the society.

Automatic Fire-Alarms. — We learn from the *Practical Engineer* that the latest invention in fire-alarms comes from New Zealand, and is known as May's automatic fire annunciator. It is an adaptation of the sagging wire principle, and the action of the apparatus is very simple, it allowing also for a separate detector to be placed in any room which it is desired to protect. Contact is made by means of a wire which, if heated, rings an electric bell, and at the same time operates an indicator which shows in which room the fire has occurred. A telegraph transmitter at the same time warns the nearest fire station. No doubt the machine would be very valuable in case of a serious fire, but it appears to us that a very slight provocation, such as the burning of a curtain or other hanging in a room, might summon the fire brigade on an utterly useless errand. There would, we think, probably be more trouble from this cause than there would be saving effected.

Franco-German Telephones.—We note that communication has now been established between Berlin and Paris by means of a telephone. The telephone line goes from Paris to Frankfort, which is, of course, connected in this way with Berlin, giving a through service, extending over some 600 miles, between Paris and Berlin. Although the distance between the two towns is so very great a voice speaking in Paris is said to be heard distinctly at Berlin. The connection seems to point to a much more amicable feeling growing between the two countries interested, and if anything is done by means of this intercommunication to forward this feeling, a great deal of good will have resulted. On the question of the price to be paid for conversations on this line, it seems rather difficult to see why the cost of telephony from London to Paris should be over one-third as much as between Berlin and Paris, as the cost of the cross-Channel cable could hardly account for it.

Train-Lighting.—In a paper on "Train-Lighting," by Mr. A. Lipschutz, is the following paragraph, which should be of some interest: "In order to arrive at the true cost of a candle-power per hour for any train light, it becomes necessary first to allow for the proper depreciation of the capital invested in stationary plants and train equipment; then to consider the expense for operating same, and, finally, to provide for renewals and repairs. As all lamps in electric train-lighting have to be renewed several times in one year, and renewals of burners in gas lighting are also necessary, these expenses must appear in a comparative statement of cost. In fact, no item should arbitrarily be considered too insignificant to enter into the estimate of cost, as it might often materially change the final figure. To light a modern train electrically requires, roughly speaking, about 30 h.p., and yet a company manufacturing apparatus for train-lighting states in its circular that the cost for power is so small as to deserve no consideration."

Trolley Lubricator.—Since the Helios Company, of Cologne, opened the traction department of their huge establishment a few years back they have shown themselves very much alive to the requirements of this branch of the electrical industry. One of the latest improvements introduced by them is an ingenious device for lubricating the trolley wire of an overhead system of conductors. It is sufficiently obvious that an effective lubrication of this sort would greatly lessen the wear both of the wire and of the bow or roller collector employed, hence the device in question may find extensive adoption. But that, of course, depends upon the efficiency of the new apparatus, since many unsuccessful attempts have already been made to attain the same end. The latest attempt certainly gives great promise of success, for we understand the apparatus evolved after careful experiment enables a thin and uniform coating of the lubricant to be spread along the wire. It is of light construction, being of aluminium, and may be carried by the collector arm or independently.

Rail Joints.—The *Scientific American* calls attention to the large share which the present imperfect form of rail joint contributes to the general din of street and railway travel. In this country, where street railways are not so extensively adopted as in America, we have less occasion to look upon the disadvantages of an imperfect rail joint from the same point of view, but the necessity for improvement on other scores is not lost sight of. We agree with our contemporary in the contention that theoretically the perfect remedy is to be found in abolishing joints altogether, and welding the rail ends. Several methods of doing this have already been practically tested, with more or less successful results. The latest system of rail welding, to which we referred at some length in our issue of the 27th ult., emanates from Germany, and accomplishes the end in question by the process of obtaining high temperatures

Digitized by Google

with the aid of aluminium, discovered by Dr. Goldschmidt, of Essen. This system, a description of which was given, has been adopted in several German towns with reported good results.

The Sounder Preferred.—In an editorial, our contemporary the *Electrical World* of New York dilates upon the relative merits of the sounder and telephone for central-station purposes. In many central stations, telephones are employed not only between the various offices of the staff, but also between the main station and substations, or between different departments of the main station itself. It seems that in a few instances these telephones have been replaced by sounders in the States, whereby the station operators signal to each other through the medium of the Morse code. The inherent disadvantages of the telephone in its application to central-station work are stated to be entirely absent in the sounder, which takes a positive delight in outsounding the loudest engines, to use the words of our contemporary, and its gleeful click can be heard by the operator with ease if his ear is close to the instrument. Having regard to the latter fact, and to the many other defects of the telephone avoided, preference is given to the sounder, notwithstanding that a trained ear is required to decipher its messages.

The Battle of the Systems.—Our contemporary the *Electrical World and Engineer* of New York, is most gratified to note that the joint session of the American Institute and the British Institute of Electrical Engineers is to be turned to such practical account as the promised discussion on "The Relative Advantages of Alternate and Continuous Currents for a General Supply of Electricity, especially with regard to other interests," suggests. It anticipates a very interesting discussion, although as regards the "other interests" involved the conclusions arrived at will have less significance in the States than outside, for in their easy way of doing things, our cousins over the water leave other undertakings to hustle for themselves without any altruistic efforts on the part of the electric light and power companies, as they themselves admit. Incidentally, our contemporary expresses a desire to hear the net average efficiencies of the two systems of distribution ruthlessly set forth—a wish hardly likely to be realised, though others join in giving it expression.

Accumulator Boats.—The *Elektrotechnischer Anzeiger* thinks one outcome of the progressive improvement of accumulators will be that electrically-propelled boats designed to accommodate from 100 to 150 passengers will prove dangerous competitors of steam-driven boats. The insignificant attendance required, involving no stoking, absence of smoke, and the possibility of attaining very high speeds, are all points in favour of their extensive introduction. At the same time, it must be remembered that the wear and tear of accumulators employed for boat propulsion is much less than in the case of road traction, since the concussions so detrimental to the life of the plates is almost entirely absent. It is also to be anticipated, considers our contemporary, that one will depart in the future from the principle of providing services of large steamers at long intervals—because small steam-engines work less economically—in favour of running small boats at short intervals. Within certain restricted limits we agree this may be true—namely, for river service and comparatively short runs—for there is a limit to the capacity of the accumulators which can be carried by a small boat.

Chicago and Electrolysis.—Some of our people in this country who are troubled with the nightmare called electrolytic action will probably hold up for an example the action of Chicago, where last month an ordinance was passed by the City Council to take effect immediately and must be complied with within one year. This ordinance reads: "Every person, firm, or corporation operating, holding, or controlling any surface or elevated railroad or any street railway within the city of Chicago, upon which cars are now or hereafter operated by electricity as a motive power, with a grounded return circuit for conveying the electricity, shall instal and maintain a metallic return circuit of such cross-section and conductivity for conveying the electricity so used as a motive power, that the maximum difference of potential will not at any time exceed one volt between any part of such metallic return circuit and any water-pipe, gas-pipe, or other metals not installed for the purpose of forming a part of such metallic return circuit, and that there will not be a variation in difference of potential exceeding half a volt between any two measurements made at the same time at points along and upon said metallic return circuit within a distance of 300ft. or less from each other. Such metallic return circuit shall be installed and maintained in accordance with the provisions of the general ordinances of the city of Chicago now or hereafter in force."

An Electric Mining Pump.—We notice in the *Electrical World* an illustrated description of an electrical miner's sinking pump which has been placed on the market by the Jeanesville, Pa., Ironworks Company. The design comprises three single-acting plungers worked from a common crankshaft with crank pins placed 120deg. apart, and these plungers produce a continuous stream to the column pipe and reduce the jarring of the same. The water-cylinders are cast in one piece, and connected to the guides by hollow castings which form a vacuum chamber one side and air-chamber on the other. Each plunger is fitted with bronze adjustable shoes, and each connecting rod fitted with bronze adjustable bearings at each end. The crankshaft is driven by two gears fitted over the discs which form the outside cheeks of the two end cranks, thus relieving the shaft of a great part of the strain that would be brought upon it if driven by a single gear at one end. It also economises space, in that no extra room whatever is required for these gears, and, what is equally important, it places them inside the main bearings. The crankshaft gearings are completely enclosed in a cast-iron frame. The motor is placed upon the top of the pump frame, and connects the crankshaft by gearing designed to give the desired speed to the pump. The pump frame is made to receive any make of motor which is adapted to this kind of work, and it may be either direct or alternating current.

Water Power in Canada.—As we have from time to time noted, some very important schemes for the utilisation of waste water power are now in course of progress in Canada. The most recent of these is, perhaps, the Hamilton and Lake Erie power canal, the construction of which was commenced at Silverdale, Car., a few weeks ago. This canal will be 6½ miles long, and will be fed by the Welland River. The Welland, it must be explained, discharges into the Niagara, the waters of which latter river are more or less driven up the channel of the Welland, owing to their great force and to the deflection at the junction. The power canal will discharge into the Jordan River, which has two or three important falls in the neighbourhood, its level at the point where the canal will discharge lying considerably lower than the head of the canal, the total fall of the latter which can be utilised for power being about 250ft. The initial instalment of plant will represent 25,000 h.p, to be increased to 50,000 h.p. or 60,000 h.p., as required. Plans of the canal show that it is to be 150ft. wide at the top, 60ft. wide at the bottom, 12ft. deep, with a current velocity of 3½ miles an hour. The Canadian

Digitized by Google

Steel Company, whose works are being erected at Welland, have contracted to take 15,000 e.h.p. of the total generated, so that the success of the undertaking is practically a foregone conclusion. It is further reported that the Ontario Power Company, of Niagara Falls, is now ready to go ahead, having obtained all the necessary legislative rights to utilise 300,000 h.p. An initial installation of 30,000 h.p. is proposed. The plans include a power canal on the Niagara River, discharging just above the Horseshoe Fall.

Tramcar versus Express Train.—It is useless to mention that this race occurred in America—in fact, between Kansas City and Leavenworth. The race was between an express passenger train of the Missouri Pacific Railway and a car of the Kansas City and Leavenworth Electric Railway. In the Missouri Valley, between Pomeroy and for two miles past Wolcott City, the lines of the two companies are parallel, on a level, and well constructed, thus ensuring good conditions for a race. On the evening in question a trolley car, having on board several city men returning from business, found itself next to the express train which leaves Kansas City at 5 p.m. The fireman of the engine ordered his stoker to pile on the coal, and he let her go at full speed; seeing this, the wattman, winking to the conductor, turned the handle of the controller, and the car went away like lightning. The passengers on both the car and train took, as they naturally would, the greatest interest in the race, waving hats and handkerchiefs. The express train held a lead of a few yards during half of the first mile, but the car caught up and kept level for about a mile. Towards the end the wattman turned on still more current, and left the train behind. The fireman of the latter had never before exercised himself so much; the train had attained its maximum speed, and when the tunnel was reached, which naturally brought the race to an end, the car had obtained a lead of 30 yards. As Mr. Herbert Wolcott, manager of the Kansas City and Leavenworth Electric Railway, was on board the car at the time of the race, it may be inferred that the race was not altogether unpremeditated. This gentleman states that the car was running at a speed of 55 miles an hour, which speed could still have been increased, whilst obviously the train had attained its maximum speed on the level.

The British Association.—The British Association will meet in Bradford in the beginning of September. The meeting of 1873, which was held at the same place, was presided over by Prof. A. W. Williamson, the distinguished chemist, whose presidential address consisted mainly of a review of the progress of chemistry up to that date. The second Bradford meeting will be presided over by Prof. Sir William Turner, the professor of anatomy at Edinburgh University. His address will consist of a general review of the progress of biology, with special reference to the structure and function of cells. Sir Alexander Binnie will preside over Section G (Mechanical Science), and his address will treat of the steps by which we have arrived at our modern conception of nature, when reviewed from a scientific standpoint. The address will be illustrated by a chronological chart, extending from 1550 to the present time, and including, collated with the births and deaths of the many distinguished men to whom we are indebted, the principal historical, scientific, and other data which mark the various periods, as well as the dates of discoveries and of publications bearing upon the subject. Monday, as usual, will be given up to the electrical engineers. The reading of the final report of the Small Screw Gauge Committee heads the list for that day. Mr. A. Mallock will then deliver a paper on "Resistance and Acceleration of Trains—Measurement of the Tractive Force," in which he will deal with the recent experiments made by him on electric and other railways to determine the acceleration, the tractive force, and the running resistance to which trains are subjected. This will be followed by a paper on the proposed "Liverpool and Manchester Electric High-Speed Railway," by Sir William Preece. Mr. Gibbings is down for "The Design and Location of Electric Generating Stations" on a large scale for supplying electric power and lighting to large districts, and Mr. Barker for "A Maximum Demand Meter," the joint invention of himself and Prof. Ewing. Tuesday will begin with a paper by Mr. J. G. W. Aldridge, entitled "The Automobile for Electric Street Traction." Prof. Goodman will describe his new invention, entitled "A New Form of Corimeter for Measuring the Wetness of Steam." Prof. Arnold, of Sheffield, will, under the title of "The Internal Architecture of Steel," set forth his theories on the ultimate molecular structure of steel and the micrographic analysis of steel in physical researches. The Friday evening discourse will be delivered by Prof. Gotch, the subject being "Animal Electricity," while that on Monday evening will be by Prof. W. Stroud, whose subject will be "Range Finders." Prof. Silvanus P. Thompson will give the lecture to the operative classes on Saturday, and will take as his subject "Electricity in the Industries."

German Statistics.—Our contemporary, the *Elektro technische Zeitschrift*, published its annual statistics relative to central-station work in Germany some weeks ago. These statistics have become a noteworthy feature of the paper in question, and from year to year provide some very interesting comparisons. The returns are corrected up to March of the current year, and should therefore represent fairly accurately the present position of central-station work in Germany. It appears there are now running upwards of 652 public supply stations in the country, representing an aggregate output of more than 230,000 kw. To these must be added 122 stations in course of construction, not to mention the numerous private installations and stations supplying energy exclusively for traction purposes, before a true conception of the advanced state of electricity supply in Germany is obtained. The existing public supply stations distribute energy for lighting and power purposes to over 900 towns and villages. Individual stations situated in agricultural districts supply energy to as many as 30 different places, frequently distributing over areas having radii of from 10 km. to 15 km. With regard to the systems of supply in vogue, we find that the continuous-current stations represent 80·4 per cent. of the total. Purely alternating or rotary current installations account for another 12·7 per cent., thus showing a very slight increase compared with the previous year, whereas the works giving a mixed supply or transforming a portion of the current generated into continuous current have increased considerably. Although the percentage of continuous-current stations is so high, the aggregate output of the continuous-current generators installed amounts to only 47·4 per cent., and the total output of these stations to 53·8 per cent. of the grand total. The difference between the generator and the total outputs is explained by the increasing employment of accumulators, which are installed at 93·1 per cent. of the continuous-current stations, and equal 37·9 per cent. of the machine output. Of the total output of all the public supply stations in Germany—namely, 230,000 kw.—continuous current accounts for 124,000 kw., this being generated in 524 stations, while 58,000 kw. represents the alternating and rotary currents generated in 83 stations, the remaining 48,000 kw. falling to mixed systems of supply in 45 stations. Of the total supply stations, six have capacities

Digitized by Google

exceeding 5,000 kw.; 46, capacities from 1,000 kw. to 5,000 kw.; 31, from 500 kw. to 1,000 kw.; 249, from 100 kw. to 500 kw.; and 320, or 46·9 per cent., less than 100 kw. The number of lamps, or their equivalent, connected to the mains has increased all round compared with the previous year, an equivalent of 251,961 kw. being actually connected, of which total 95,731 kw., or 38 per cent., is represented by motors. Since the year 1898 the number of central supply stations and lamps connected have doubled, while the output of the motors connected has trebled. In conclusion, it may be added that 25 per cent. only of the stations are municipally owned.

Our Latest Cruisers.—In the course of a long article dealing critically with the naval manœuvres recently concluded, the special correspondent of the *Daily Chronicle* writes as follows: "From the man to the ship. The constructive defects of our older warships have been discussed in the past *ad lib.*, and I see no object in wasting ink upon them here. About our latest craft, the cruisers of the 'Diadem' class, there are, however, a few things to be said. Good ships and all as they are, they are not triumphs of naval architecture. Space is undoubtedly wasted in them; minor constructive errors abound. For instance, they are 10 years behind the times in the matter of ammunition hoists. These are cumbersome manual ones, able to serve the 6in. quick-firers—theoretically able to fire five to ten shots a minute—at the rate of only two a minute! For the last five years all foreign ships have had electric hoists, and, consequently, are able to fire at least twice as fast. In other words, four guns in, say, a Japanese cruiser built at Elswick are worth eight in the latest thing in cruisers in our fleet. From time to time it has been argued that electric hoists are unreliable. This is rubbish. If they break down there is always hand gear to fall back upon, but there is no more reason why they should fail than that the ship's searchlights or ordinary lamps should fail. Now, time after time naval officers have asked for electric hoists. They have asked in vain. Even to-day the matter has got no further than that one is being experimented with somewhere. Speaking bluntly, this sort of thing is criminal. Officers afloat know a great deal better what is wanted than the people at the Admiralty who decide these things. The Lords of the Admiralty are far less powerful people than the world at large imagines. The real rulers in too many matters are certain obscure civilian clerks. These are they who control the pigeon-holes, and into a pigeon-hole whence it will never emerge goes everything that they can put there. It saves labour. From such internal evidence as is procurable, there is not good reason to suppose that Lords of the Admiralty are wilfully and criminally negligent. If all this time they have wilfully ignored the requests for electric hoists they would be that, and more. Where, then, have these requests gone to? Who is the man who has saved himself labour by suppressing them? It can be laid at his door if a proper search is made for him. What is more, it ought to be laid, and an example made—the crueller the example the better—for nothing short of drastic measures will stop this shameful system whereby the navy suffers so that a few lazy clerks may continue lazy. I do not know whether any of these folk will read these lines—if so, no doubt they will feel I am laying it on far too thickly. Am I? Could they only go unknown into any wardroom in the navy they would soon hold me a very milk-and-water accuser. For this is the sort of thing they would hear: 'If I had my way I'd take the —— brute, trice him up, and give him six dozen well laid on.' 'If 'twasn't for the absurd sentiment there is nowadays they'd hang 'em. I'll lay 10 to 1 that if we go to war there'll be a fleet lost, because some clerk pigeon-holes a report for fear he'll get an extra 10 minutes' work.' All this and more than this he would hear."

Sparking Experiments.—In the *Scientific American* we notice another article by Prof. J. Trowbridge on "The Electrical Plant used at the Jefferson Laboratory at Harvard University." In this article he describes some experiments he has conducted with the large battery installed in the laboratory. In connection with this battery plant, glass condensers serve the function of Leyden jars. There are 12 trays, carrying 25 glass plates each, there being thus 300 plates in all. The condensers are made ⅛in. thick, and they have a coated surface of tinfoil 16in. by 20in.; the capacity of the entire condenser in multiple is about 1·8 microfarads. When the condensers are charged to 20,000 volts and discharged in series a spark 6½ft. in air is produced. The professor experimented to find out if lightning could pass through a small orifice, and in this way noted the effect of very powerful discharges. A plate of glass 5ft. square and ¼in. thick was placed between the spark terminals, the plate being of this size to prevent the sparks from passing around the edges of it. The plate had a small hole bored through it at its centre, and this orifice could be made much smaller by filling the hole with paraffin and making a needle hole in the paraffin. It was found that when the discharge terminals were in line with the hole and 5ft. apart the discharge would pass through the minutest orifice; but the portion which passed through the hole was only a fraction of the entire discharge, for there was an inductive action over the entire surface of the glass. When the hole in the plate was entirely closed by paraffin and the spark terminals placed opposite each other, about 4ft. apart, with the glass plate midway between them, the spark jumped from one terminal to the surface of the glass, while no spark was seen on the opposite side of the glass. On close inspection, however, a faint brush discharge could be detected on the sparkless terminal. When the spark terminals were not opposite, the spark also sought the orifice, but the discharge usually jumped to the nearest point of the glass and then pursued a devious way to the hole. The professor then experimented with the discharge of the condensers in multiple. In the experiment a fine iron wire about 6in. long was stretched around the spark gap, serving as a shunt to the latter. It was found that the wire was deflagrated at the instant that the spark passed across the air gap. This led Prof. Trowbridge to think that a small spark could occur under certain conditions inside a metallic cage, and in the case of very powerful lightning discharges a wire cage would not be a perfect protection for a powder magazine. He also used the strong current from the entire battery to excite discharges in hydrogen, for the spectroscopic study of the gas. From this he found that aqueous vapour became manifest in all glass vessels which were filled with apparently pure dry nitrogen or hydrogen. The powerful discharges drove off the aqueous vapour from the glass, notwithstanding the glass had been subjected to a long process of heating to expel the vapour during the exhaustion of the tubes. The most interesting result, however, was the production of the X-rays for the first time by a steady current. An X-ray tube was connected to the terminals of the battery and a water resistance of about a million ohms inserted in the circuit. The tube was then heated by an external source of heat. In an instant the tube lit up with a most brilliant exhibition of X-rays, and photographs taken by means of them showed unmistakable evidences of the tendons and muscles, and he hoped that when the right conditions were reached he could obtain satisfactory photographs of these objects.

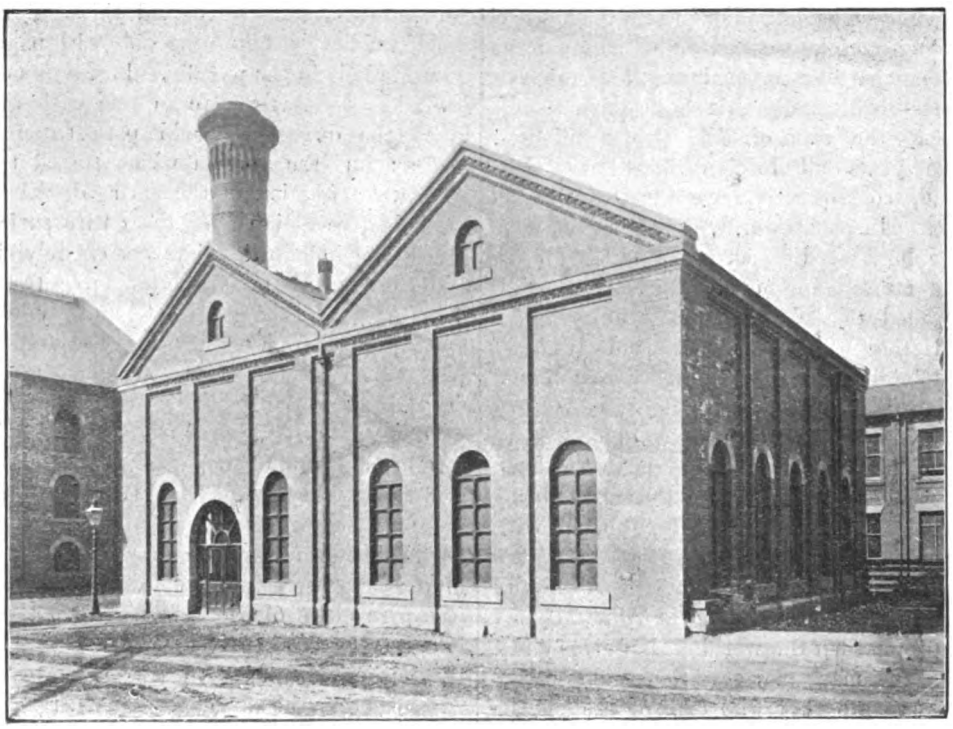
LEIGH CORPORATION ELECTRICITY WORKS.

Before describing these works, a few notes regarding their history may be given. Notice was served on the Leigh Local Board by the Cheshire House-to-House Electricity Company, Limited, in the year 1889 of the company's intention to apply for an electric lighting provisional order. It was agreed by the Board to oppose such application; but nothing came of the notice, nor was anything further done in the matter until May, 1894, when a committee was appointed by the Town Council to visit other towns where electricity works were in operation, and to report fully on the whole question of electricity supply. The report of this sub-committee was favourably accepted by the Council, who afterwards passed a resolution that application be made for a provisional order, which received final grant in June of 1895. Nothing was further done until the year of 1897, when the Council asked Mr. John Foster, the present engineer and manager of the Corporation's gas, water, and electricity undertakings, to prepare and report on a suitable scheme to enable them to carry out the order. The scheme was laid before the Council in May, 1898, and received their approval. At the same time it was decided to apply to the Local Government Board for sanction to borrow the sum of £10,500, which sanction was duly received on the 22nd of the following October. Previous to receiving the sanction for the loan specifications had been prepared, tenders were received, and contracts for the whole of the work were placed, subject to the sanction for the loan being given by the Local Government Board. Work was commenced on the buildings, etc., in March of 1899, and the current turned on for the first time early in January of the current year. At the present time 3,000 lamps (equivalent 8 c.p.) are connected, besides two motors of 55 b.h.p. aggregate capacity, whilst there are quite another 1,000 8-c.p. lamps practically ready to be connected to the mains. Application is being made to the Local Government Board for sanction to borrow a further sum of £5,000 for a large extension of mains, etc.



Leigh Electricity Works—Exterior.

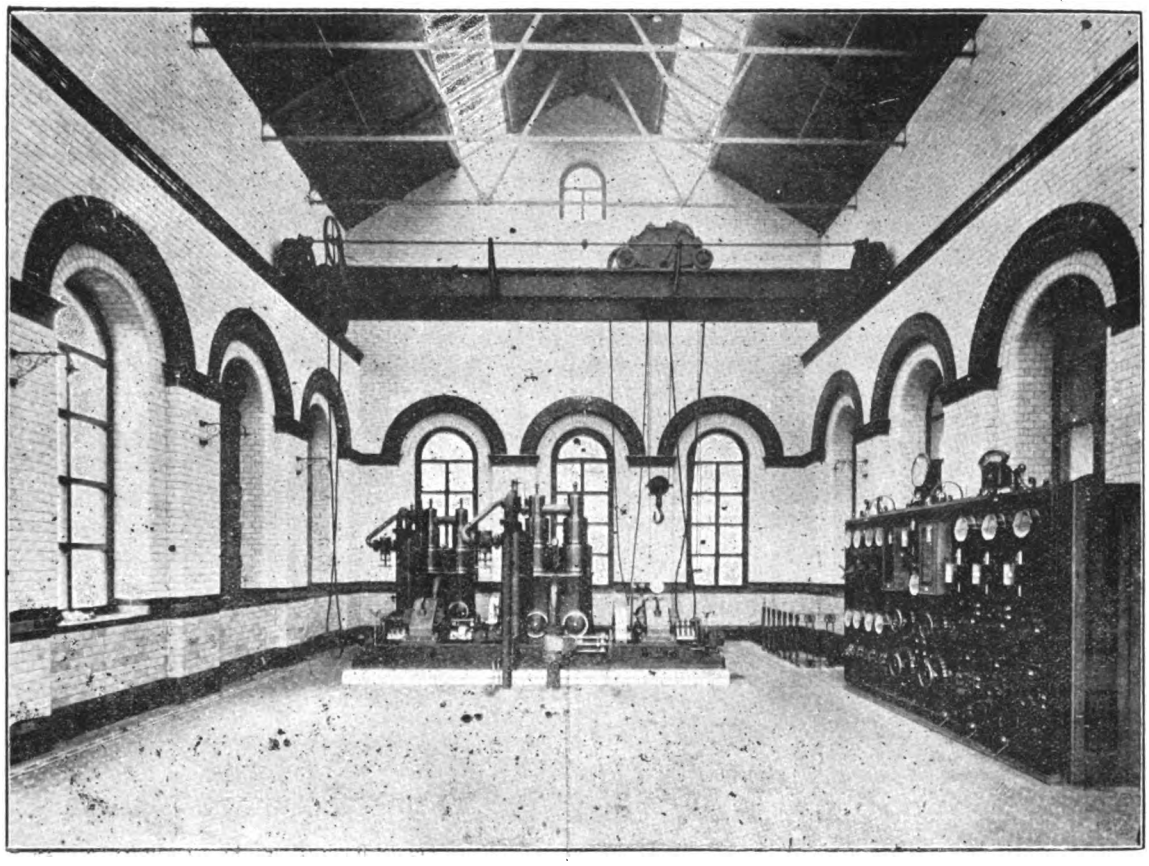
As at present arranged, the generating station buildings comprise only the engine and accumulator rooms, each 50ft. long by 32ft. wide, steam being obtained from the boilers of the gas department, which are arranged to utilise the waste heat given off the gas-retort furnaces. Space is left on one side of the engine-room to erect a boiler-house when required. The steam generating plant belonging to the gas department consists of two Lancashire boilers, 30ft. long by 8ft. 6in. diameter, fitted with Deighton's patent corrugated flues, and designed to work at a pressure of 130lb. per square inch. They were made by Messrs. Clayton, Son, and Co., Limited, the whole of the mountings being of Hopkinson's make. Musgrave's superheaters are fixed immediately behind, each superheater consisting of 38 1¼in. tubes, with the usual safety valves, thermometer pockets, etc. There are also two sets of Green's economisers erected, one set to each boiler, consisting of 96 pipes complete, with scrapers and gearing. The water for the boilers is obtained from a borehole, and before passing into the boilers is pumped into a tank, and then passed through a water-softening apparatus, made by Messrs. Mather and Platt, Limited. The steam-main consists of one single main, 8in. diameter, with subsidiary mains, 4in. diameter, of lap-welded steel (wrought) with wrought-iron flanges welded on. A Brooke's steam-dryer is provided, and Geipel steam-traps. The steam joints are made with gunmetal rings and mastic cement, the exhaust pipes being of cast iron 10in. and 6in. in diameter.

The generating plant at present comprises two direct-coupled sets, one set consisting of a Willans and Robinson's two-crank compound engine coupled to a Mather and Platt four-pole shunt-wound dynamo rated at 200 amperes, 460 volts, while the second set consists of a Willans and Robinson's two-crank compound engine with a Mather and Platt four-pole shunt-wound dynamo coupled at each end of the crankshaft, each dynamo being capable of giving 135 amperes at 300 volts. This set is used at present for charging the battery and for balancing the three-wire system. At present the engines are running non-condensing, but can with a slight alteration be run condensing when required. There is provided in the engine-room an eight-ton overhead travelling crane, made by Messrs. James Carrick and Sons, Limited, of Edinburgh, the crane being worked by ropes from the ground level.

The switchboard, which was supplied by Messrs. Dorman and Smith, of Manchester, is arranged for a three-wire system of distribution at a working pressure between the outers of 440 volts, and consists of three dynamo panels, four feeder panels, and a middle wire panel. Each machine panel is provided with one minimum automatic cut-out, one field-breaking switch interlocked with a single-pole knife switch, shunt regulating switch, ammeter, and voltmeter. There is also a Ferranti ampere-hour meter in circuit with each machine. Each feeder panel is provided with an ammeter, duplex switch, and fuses, also Thomson-Houston recording wattmeters. On the middle wire panel are mounted the battery charge and discharge switches, battery emergency switches and fuses, reversible ampere-hour

Digitized by Google

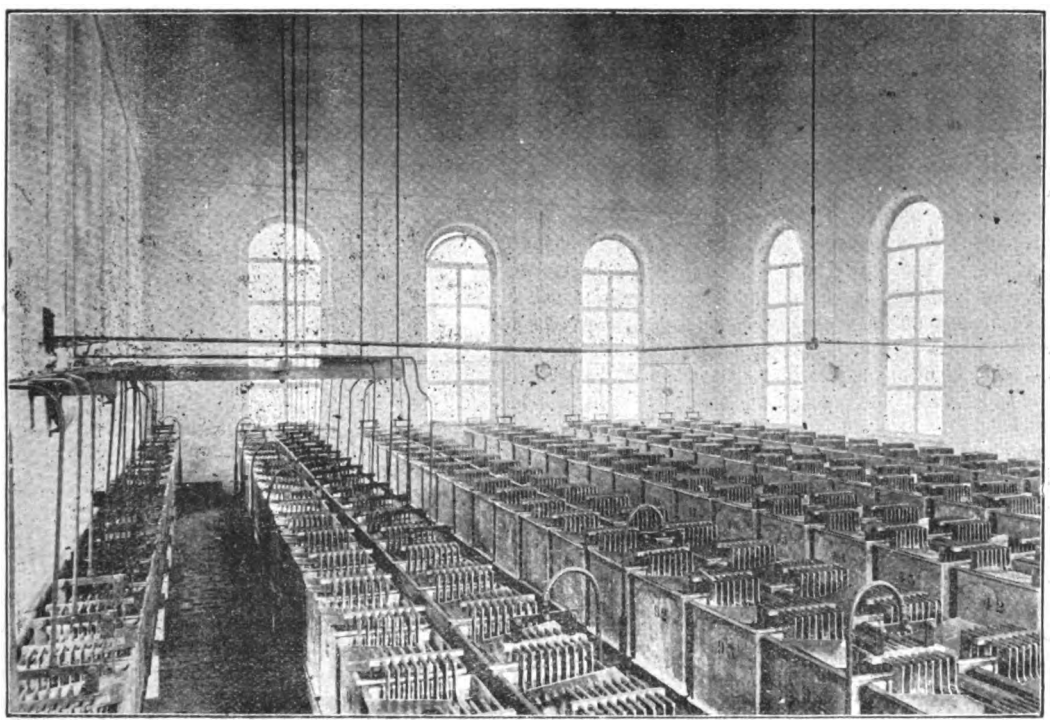
meters, polarised ammeter, battery voltmeter, and two Weston feeder voltmeters. The whole of the ammeters and voltmeters, with the exception of the feeder voltmeters, are of Lord Kelvin's multicellular type.



Leigh Electricity Works—Dynamo-Room.

The accumulators are of the Chloride C R type in lead boxes, the battery containing 240 cells, having a sum capacity of 1,000 ampere-hours, and being capable of discharging at the rate of 300 amperes for one hour without injury. The battery is fixed on one tier, with ample space to get at each cell, the regulating cells being connected to the switchboard with bare copper rods run on special insulators, and painted throughout with anti-sulphuric enamel.

The mains were supplied and laid down by the British Insulated Wire Company, Limited, and are of their three-core, paper-insulated, lead-covered type. The feeders are drawn into stoneware casing, the whole of the distributing mains being laid in stoneware troughs filled up with compound. The service cables are of the two-core type, lead covered and steel armoured, and are laid direct into the ground. At present there are two triple-concentric feeders of ·25, ·15, ·25 square inch cross-section, with subsidiary feeders of ·15, ·075, ·15 square inch cross-section. The triple-concentric distributing mains are of ·1, ·05, ·1, and ·05, ·025, ·05 diameter, laid complete with the usual disconnecting boxes, etc.



Leigh Electricity Works—Battery-Room.

The Wright demand indicator system of charging has

Digitized by Google

been adopted, the price per unit for lighting being 7d. for the first hour and 2½d. afterwards, while 3d. per unit for the first hour and 1½d. per unit afterwards is charged for power. The Corporation have decided to hire out motors, indicators, and meters, the latter, of the Chamberlain and Hookham type, being also fixed free.

THE EVOLUTION OF SWITCH GEARS FOR HIGH-PRESSURE ALTERNATING CURRENTS.

BY W. E. WARRILOW.

(Continued from page 190.)

BRUSH.

The Brush Electrical Engineering Company were among the pioneers of alternating-current working, and they consequently had the problem of switching apparatus to deal with. The early workers of any system have to bear the brunt of considerable experimenting, which proves a very expensive item, though a practical result is generally the outcome of such labour. This was the case with the Brush Company, who equipped many stations with switching appliances as well as other apparatus. The high-tension switch shown in Fig. 1 is the now well-known "trigger" switch. It consists of two brass fittings mounted at either

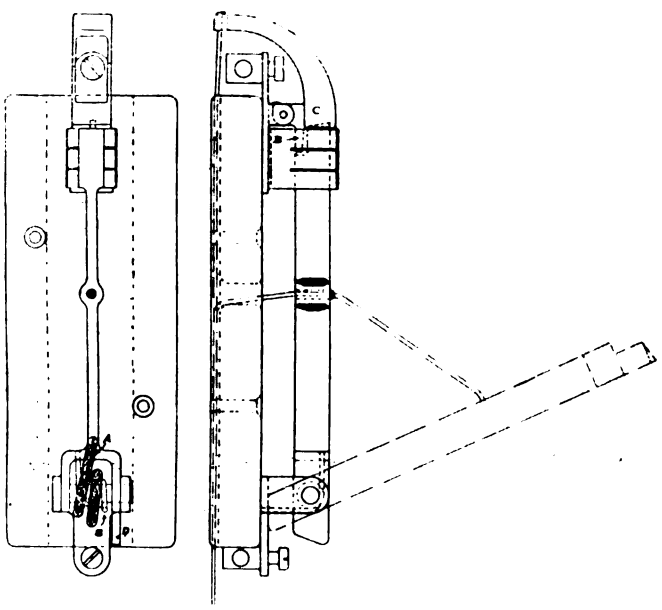


FIG. 1.—Brush Trigger Switch.

end of a porcelain base. The lower one forms a bearing, to which is pivoted the lever used to couple the two fittings together, and thus complete the circuit. This lever is operated by a catgut cord fastened near its centre and passing through a hole in the base down the back to the bottom of the switch. On pulling this cord, the lever is drawn into the contact at the top, and the spring, S, at the pivoted end is put in tension. A catch, C, held in one position by a spring, closes over a small projection at the end of the arm, and this serves to hold the switch in the "on" position. The catch above mentioned has another cord attached to it to enable the switch to be opened, which result is effected by giving the cord a smart jerk, when the lever is thrown out of the contact jaw by the projection on the catch seen at B. The tension already existing in the spring, S, carries the lever quickly away from the upper contact. An extension of the lever shown at D answers the purpose of a damper to the blow caused by the opening of the switch. Terminals are provided on each fitting for the necessary cable connections. The moving lever is supplied with current by the flexible connection seen at A, which ensures a good contact being made between the bearing and the moving part.

Fig. 2 represents a switch constructed on the same principle as the foregoing, but intended to deal with larger currents, consequently the parts are more heavily made. The blow of the arm when suddenly released is taken by the flat spring, S, and the small knob seen at the end of the catgut cord is intended to provide a good grip when opening or closing the switch. A knob for each cord is

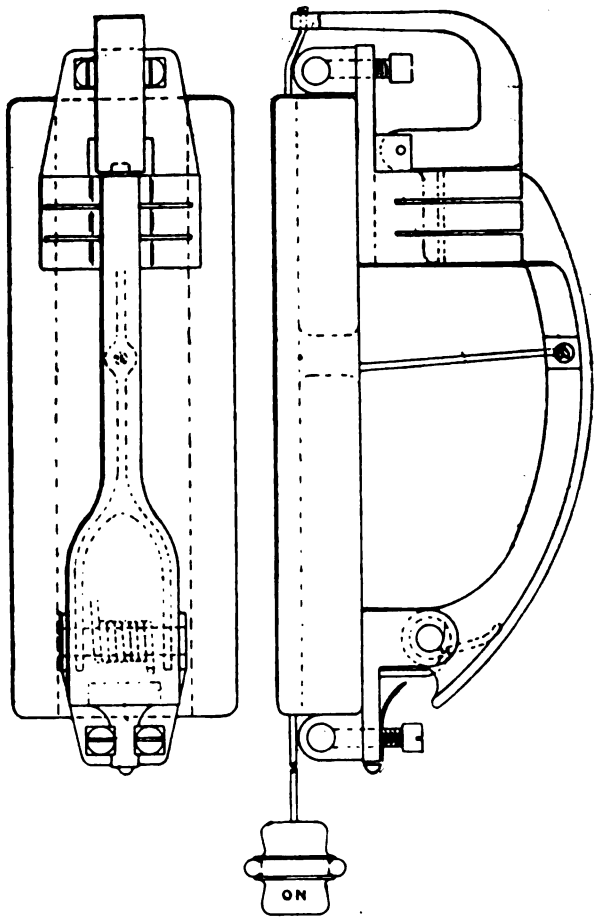

FIG. 2.—Brush Trigger Switch for Heavy Currents.

attached, marked "On" and "Off" respectively. A recess at the back of the base, shown by the dotted lines, forms a

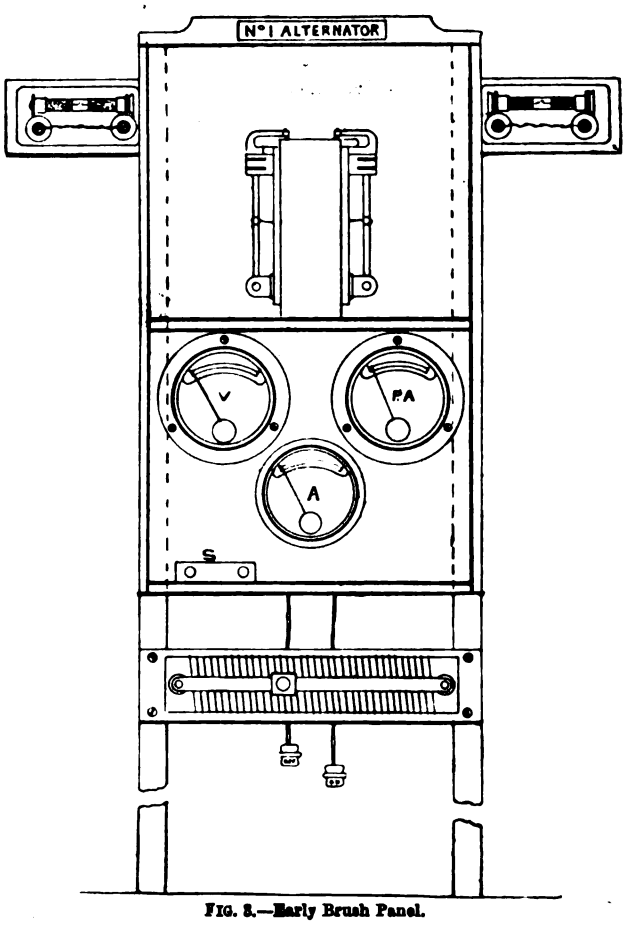

FIG. 3.—Early Brush Panel.

channel, allowing free play for both cords, without grooving the panel on which the switch is mounted. This type

Digitized by Google

of switch was introduced in 1884. The necessity for some reliable means of automatically opening the circuit in case of mishaps on the mains, brought about the introduction of a high-tension fuse. The type first constructed by the Brush Company for small currents was the Mordey sand fuse. This consists of a glass tube provided at each end with a brass cap, to which the fuse wire is soldered after being drawn into the tube. Previous to the cementing on of the caps the tube is partially filled with sand, a space of about ½in. being left open in the middle, paper wads keeping the sand in its place. The caps are provided with projections, which fit into recesses in spring clips, these latter firmly holding the fuse in position and placing it in circuit. As a dynamo main fuse it is used as a shunt to a wire of larger section, but should this melt, the sand fuse will disperse the arc (Fig. 3). An alternator panel equipped with these fuses and trigger switches is shown by Fig. 5. The body of the panel is strongly constructed of teak, and divided into two compartments. The upper one, lined with asbestos, carries the switches, and the lower one is fitted with the instruments. This last section has a glass door fitted to it. The fuses are mounted at the top of the board, on brackets fixed to the sides of the upper section. The switches are operated by the catgut cords (spoken of above), which pass through the upper and lower partitions, and terminate in porcelain knobs. Below the high-pressure panel is screwed the shunt rheostat for the regulation of the voltage of the machine. This is shown in detail in Fig. 4. It is made up of a number of turns of wire on a slate slab, which is mounted on a polished teak base. Spanning these wires is a copper bridge mounted on teak pillars, and a slider is made to move up and down this bridge. Fastened to the slider is a spring carrying a

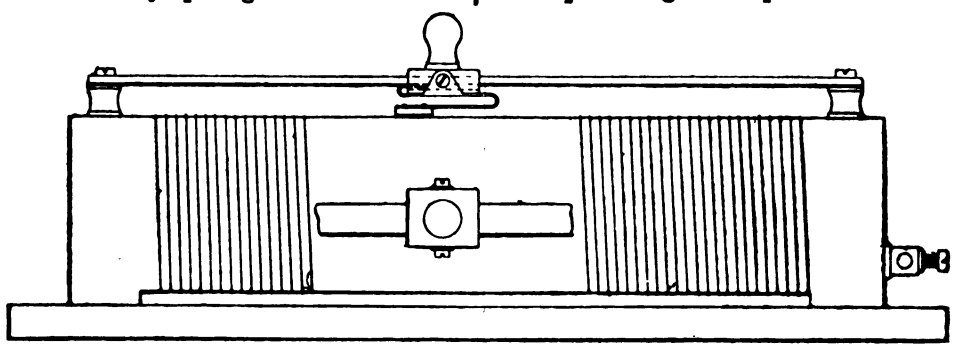

FIG. 4.—Brush Rheostat.

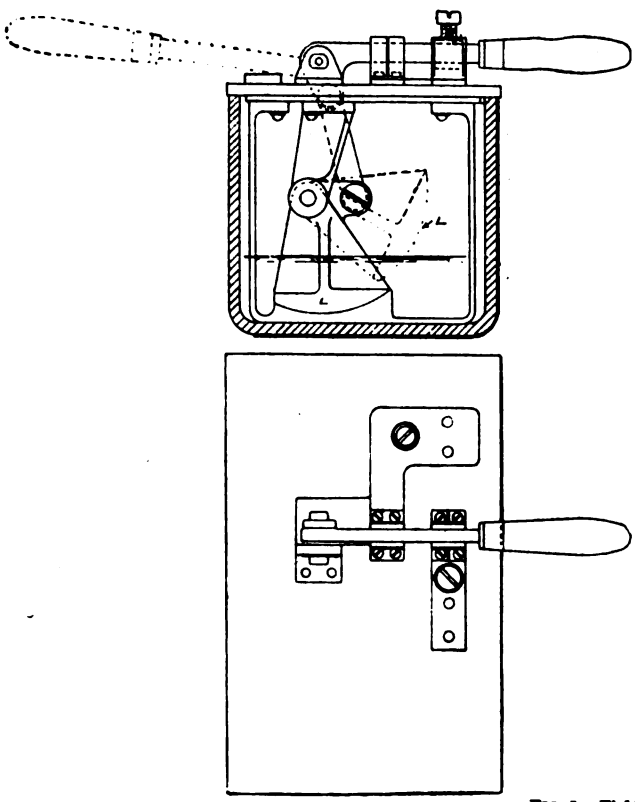

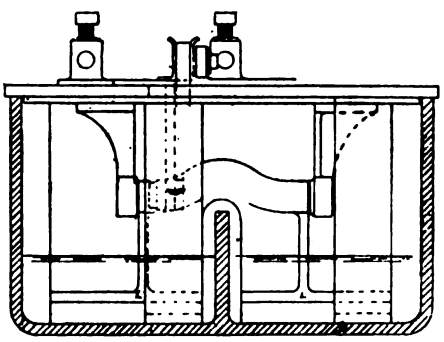

FIG. 5.—Field-Breaking Switch.

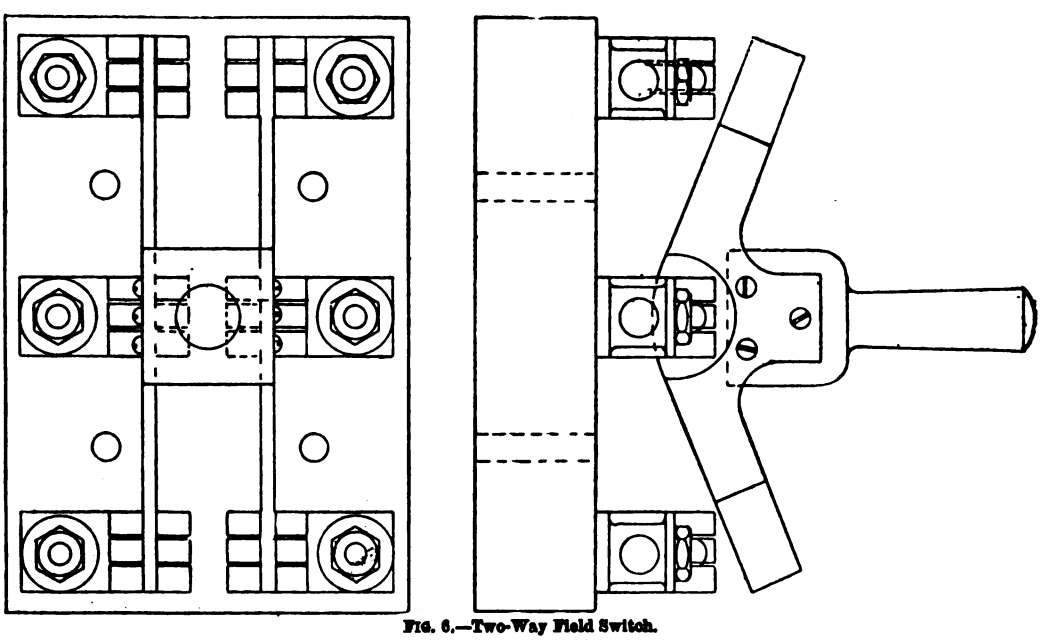

FIG. 6.—Two-Way Field Switch.

Digitized by Google

copper contact-piece, and this spring is arranged to pass under the slider in such a manner that the latter is always kept well in contact with bridge. A fine adjustment could be obtained with a resistance of this class, and the space occupied was small. Its arrangement under the panel in Fig. 3 will illustrate this. In the same figure, V is the machine voltmeter, taken off one coil or placed in circuit with the secondary of a small transformer; P A, primary

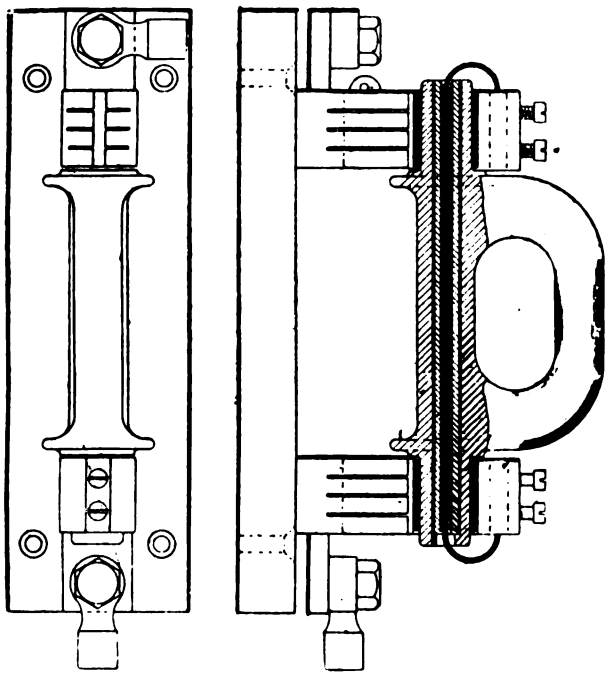

FIG. 7.—Bates Fuse—Open Type.

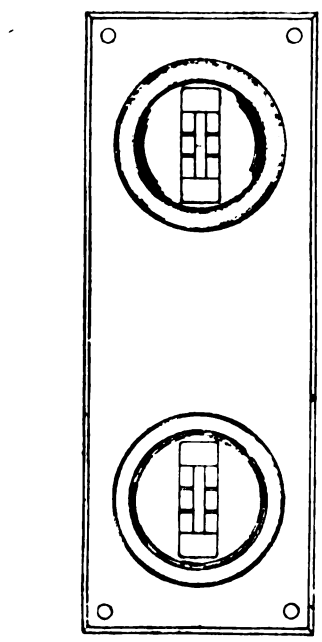
ammeter; A, exciter ammeter; and S, the plug contacts for the synchroniser. One plug switch for this latter was provided for the whole board, so that two might not be inserted at once.

In conjunction with the panel above described a liquid switch for opening the exciter circuit was provided, an ordinary switch being found unsuitable on account of the arc produced by the breaking of an inductive circuit.



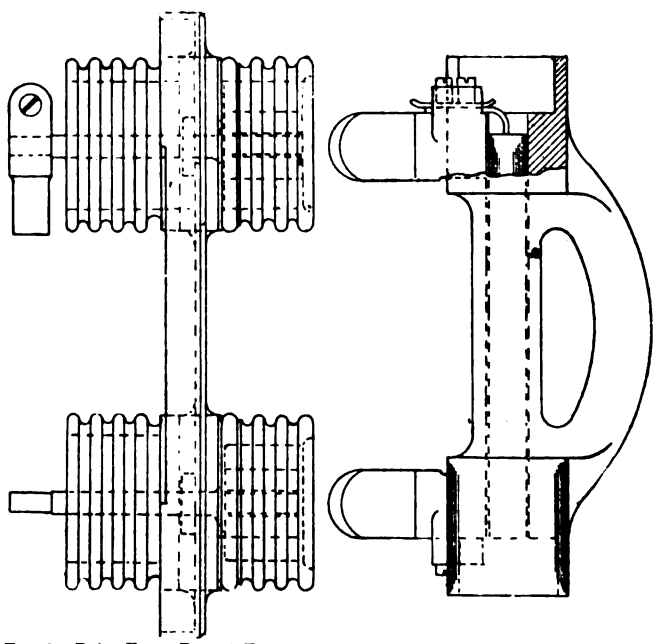


FIG. 8.—Bates Fuse—Recent Type.

Fig. 5 illustrates this switch, which consists of a wooden base fitted with the means of opening the circuit and a stoneware pot containing the liquid. Screwed to the base are two contacts, which are joined together by a brass arm when the switch is on. This lever is pivoted at one end and fitted with a handle at the other, and it is made to carry a link, which lifts two lead castings, shown at L. These latter are so shaped that they make a good contact with other lead castings connected electrically to the contacts on the base. When the field circuit has to be broken, the lever is put over to the dotted position, when current flows from one terminal to the other by way of the fixed lead castings, the liquid, and the moving leads. The stoneware pot is divided by a partition into two cells, so that two breaks are made in the circuit, there being two moving lead plates, which are joined together, and two

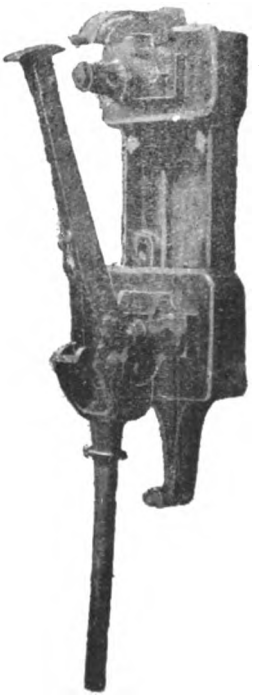

FIG. 9.—Brush Switch for Heavy Currents.

fixed plates, each coupled to the terminals of the switch. A two-way switch, as shown by Fig. 6, was used in connection with independent exciters and exciters on the alternator shaft, so that should the latter fail, the switch when put over would couple the former to the field. Such a switch is, of course, unsuitable for breaking an arc.

The sand fuse above described was only suitable for small currents, so a fuse similar to that shown in Fig. 7 was brought out. This is the now widely used Bates fuse, which consists of a porcelain base carrying two contacts, and a porcelain handle having two blades cemented at each end and joined by the fuse, which passes through a fireclay pipe pushed into a channel in the handle. The upper blade has a projection on it through which a small pin is passed, to act as a hinge in closing the circuit with the fuse. Fig. 8 illustrates the most recent type, in which all parts are carefully covered in. The contact jaws are

Digitized by Google

covered by porcelain insulators having a narrow slot, and the screws for fixing the fuse wire are well recessed in the handle. To reduce the possibilities of breakage, the base is constructed of cast iron of small section, and the insulators for the jaws are cemented into it. This gives a sound mechanical structure to the fuse while considerably reducing its weight. In cases where larger machines had to be dealt with, the panel arrangement in Fig. 3 was modified in the following manner: In place of the trigger

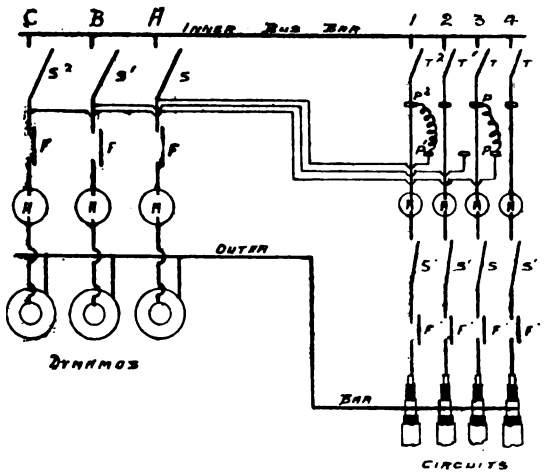

FIG. 10.

switches, two Bates fuses were fixed to the upper panel, and separated from one another by a marble slab. The switches were not used, but a type similar to that shown in the adjoining photo (Fig. 9) was fixed on the wall close to the panel and coupled to the machine. The switch is shown open, but it could be closed by raising the handle slightly above the horizontal, when a catch was released, to allow the arm to pass under the laminated contact. Fastened along the back of the arm was a strong flat spring, held at

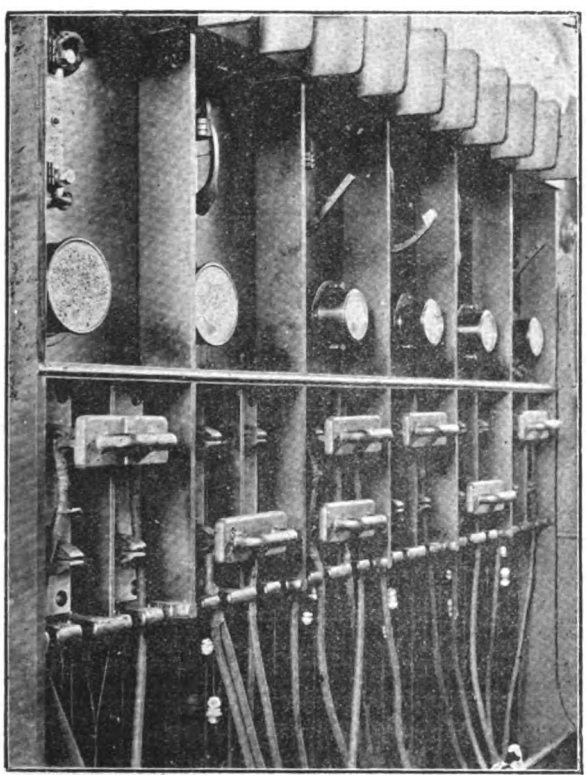

FIG. 11.—Circuit Plugboard for Separate Running of Alternators (by permission of Mr. A. B. Mountain, Borough Electrical Engineer, Huddersfield).

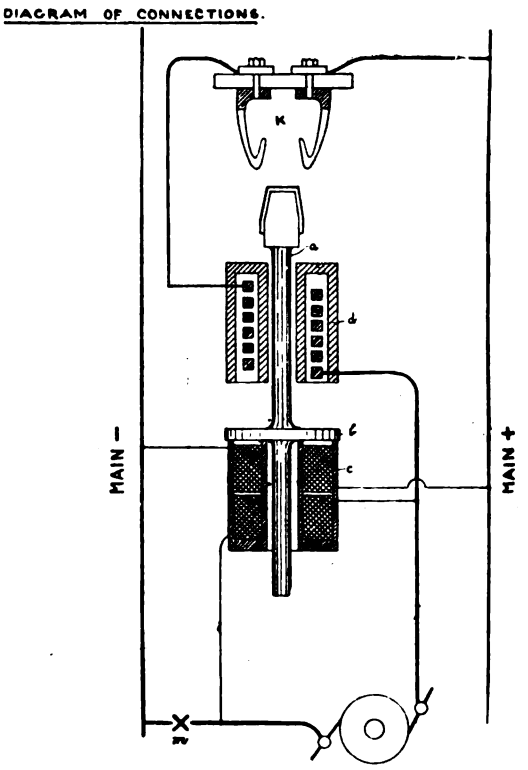
one end only by two bolts, the other end being left free and in such a position that a smart blow could be given to it by the handle, when the switch would fly quickly from the contact. The break was very long, and to prevent the operator receiving a blow on the head, a bar was provided against which the arm struck. It was impossible for the arm to fly back into the contact, nor could it be pushed in by any other means than the handle.

The panels equipped as above described were placed opposite the alternator to which they were connected, and were themselves coupled together by rubber cables run in wood casings. In some cases where these panels were used the alternators were run on separate circuits, but synchronised for a few minutes while the transference was being effected. Fig. 10 is a diagram showing how this

FIG. 12.—Raworth's Patent Automatic Switching Gear for use with Continuous-Current Dynamos or Exciters.

change could be made without interruption of the supply. A, B, C are machine panels fitted with switch, S, fuse, F, and ammeter, A. 1, 2, 3, etc., are circuits to be supplied, also fitted with switches, fuses, and ammeters. P, P^1, P^2 are plug contacts, which could be coupled together by a plug and jack cord. When one machine, A, say, is feeding all circuits, the switches, T, T_1, etc., will be closed, and no



F 13.

plugs, P, will be inserted but should B machine need to help with the load, it will be paralleled by closing S^1, plugs P^1 P^2 with cords will be inserted, and T^2 opened. When machine ammeter on B reads current on No. 1 circuit, switch S^1 is opened, which operation will separate B machine from A machine. The adjoining photograph (Fig. 11) shows a board connected up on this plan. The trigger switches, seen at the top, are represented in the diagram by T, T_1, etc., while the plugs and cords corre-

Digitized by Google

spond with P_1, P_2, etc. The arrangement shown was originally double-pole, but was subsequently made single-pole on the earthing of the outer.

The isolated panel arrangement reached its highest stage in the Raworth switch pillars. These were ornamental castings, which contained the necessary switches and instruments, and the apparatus was so compact in form that it could be placed on the floor of the engine-room opposite each machine. The photograph (Fig. 12) illustrates a pillar for use with continuous-current dynamos or exciters, Fig. 13 showing a diagram of its connections. The switch closes automatically when the dynamo has attained its normal voltage, but should this voltage fall below a certain point the circuit is opened. The main switch is carried on a vertical rod, *a*, on which is an iron armature, *b*, moving between two electromagnets, *c* and *d*. The lower one, *c*, is magnetised by a shunt from the mains and demagnetised by a shunt from the dynamo terminals, while the upper one, *d*, is magnetised by the main current from the machine.

FIG. 14.—Raworth's Patent Interlocked Switching Gear for use with Alternators working in Parallel.

When the dynamo is at rest, the lower magnet binds the armature down and locks the switch out of action, but when the dynamo is giving its full voltage, the magnet is demagnetised and the switch is closed by means of a weighted lever, and kept closed by the magnet, *d*. Upon steam being turned off the dynamo, the switch is opened by the falling of the armature by gravity. The weighted lever above mentioned has, on starting the engine, to be put in gear with the switch by means of a small catch or pawl, which automatically releases when the switch closes. A pillar for use with alternators is shown in the photograph (Fig 14). The arrangement, which is very neat, comprises two main switches, one field switch, one synchroniser switch, one synchroniser, one voltmeter, and two lamps for synchronising, one main voltmeter, one main ammeter, and one field ammeter.

The main switches are fixed at the top of the pillar, and are of the water break type. Below these are the synchronising lamps and voltmeter, and immediately beneath are three instruments—main voltmeter in the centre, main ammeter on the right, and field ammeter on the left. The handles seen under the instruments are for operating the switches, and they are marked 1, 2, 3 respectively, representing the order in which they should be closed. In the centre is the main switch, on its right is the synchroniser switch, and on its left the field switch. These handles are so constructed that they interlock with one another to effect the following objects: The main switch cannot be closed until the field switch is closed and the field fully excited, also not until the synchroniser switch is closed. The field switch cannot be opened when the main switches are closed, these latter being in their turn locked by shutting off the synchroniser switch. The advantages of such an interlocking system become most evident when alternators are run in parallel.

In connection with machine switch pillars above described, a feeder pillar constructed on very similar lines is used. This is shown by the photograph (Fig. 15). It takes the form of a cast-iron pillar carrying main switches, fuses,

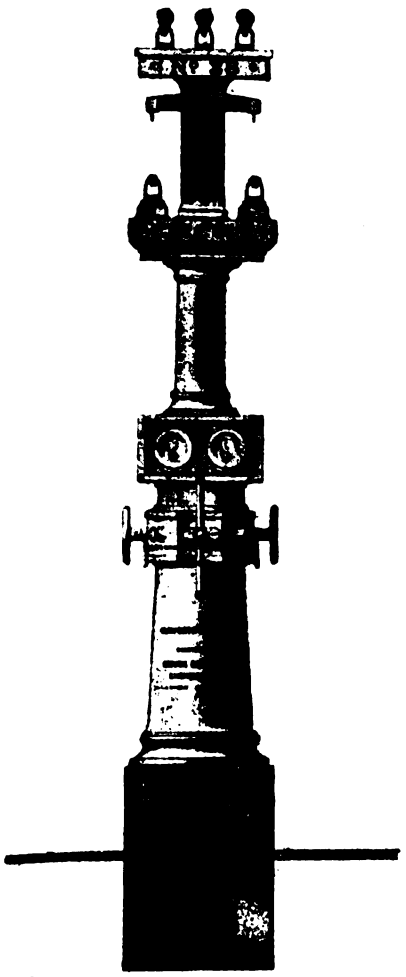


FIG. 5.—Raworth's Patent Interlocked Switching Gear for Main Feeders, Continuous or Alternating Current.

ammeter, voltmeter, and regulating gear. In the base of the pillar where the leads enter there is a switch for disconnecting the upper portion of the pillar, but at the same time establishing the circuit. This enables instruments, etc., to be examined or repaired without cutting off the feeder. At the top of the pillar are fixed three fuses, any one of which can be put in circuit by turning the right-hand lever, which, however, cannot be moved unless the main switch is open. Below the fuses are arranged double-pole switches operated by the central handle, which is locked by a trigger. This trigger must be released before the switch can be opened or closed. To the left of the centre handle is the short-circuiting switch. The hand-wheels seen on each side of the pillar are for purposes of regulation. Raworth's patent universal contact, as shown by Figs. 16 (1, 2, 3, 4, 5), is used with all switches and fuses above destribed. The contact-piece is a casting divided into a number of laminations which present many contact surfaces, and remain parallel or at the same angle to each other under varying degrees of pressure. For taper

Digitized by Google

connections the contact surfaces are arranged at such an angle that the bar or plug will stick between the jaws, but may be removed by the exertion of a very slight force. With these contact-pieces the surface presented is fully

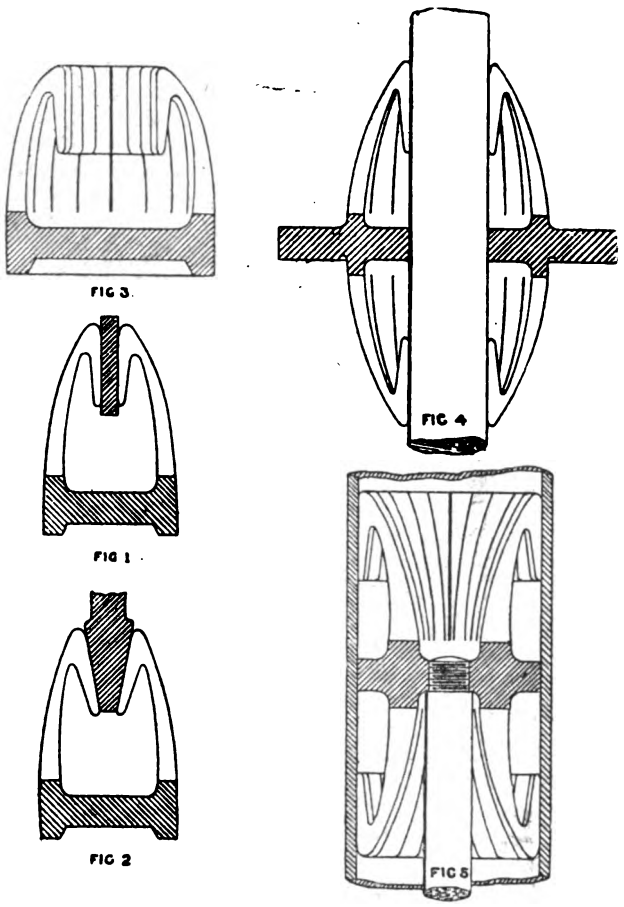

FIG 16.—Raworth's Patent Universal Electrical Contact.

four times the sectional area of the metal, and they are standardised for currents up to 1,000 amperes.

(To be continued.)

THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

EIGHTH ANNUAL MEETING AT KIEL.

[BY OUR OWN CORRESPONDENT.]

(Continued from page 193.)

In my last article I referred briefly to the Bremer arc described in an interesting contribution to the proceedings of the Verband by Prof. Dr. Wedding. The subject is of sufficient interest to merit further notice, and I shall therefore venture to give more room to Prof. Wedding's conclusions, which are reproduced with diagrams in the *Elektrotechnische Zeitschrift*. After enumerating the several disadvantages attending the use of the ordinary type of arc lamp, Prof. Wedding proceeds somewhat as follows: "Repeated attempts have been made to remedy the inherent defects of the arc lamp by impregnating in various ways the carbons employed. These experiments have, indeed, tended to greater steadiness and a more uniform colour of the arc, but have never given decisive results. However, by incorporating with the carbon 20 to 50 per cent. of non-conducting metallic salts, such as calcium, silicium, or magnesium compounds, Herr H. Bremer, of Neheim, has discovered a means whereby a far higher efficiency may be obtained. The first investigations conducted by me in connection with carbons of such composition were with two continuous-current arc lamps consuming respectively 12 and 60 amperes, and an alternating-current arc taking 6·5 amperes. I used carbons of special composition only on the positive sides of the continuous-current lamps. These carbons contained an admixture of calcium. Table I. gives the light intensities corresponding to different angles of the arc with the horizontal plane obtained with the smaller lamp, while Fig. 1 gives a graphic representation of the same. Fig. 1 renders it apparent that the intensity of the light obtained at angles from 45deg. to 90deg. remained practically constant, and then decreased towards the horizontal by as much as 1,000 c.p. The mean current strength of 12·3 amperes underwent a maximum variation of 0·3 ampere during these measurements, and the terminal potential of 44·4 volts a maximum of 2·5 volts. The mean consumption of energy amounted to 546 watts, the maximum intensity of light to 6,400 candles, and the hemispherical intensity of light to 4,320 candles. The specific consumption of the lamp was consequently $\frac{546}{4,320} = 0{\cdot}120$ watt.

Table II. gives the measurements for the same lamp fitted with a globe and consuming 12·2 amperes at 44·6 volts terminal potential—that is to say, 543 watts. It is apparent from the graphic representation (Fig. 2) that the lamps still yielded 1,440 candles when in a horizontal position, while up to an angle of 48deg. above the horizontal there remained 500 c.p. As a consequence of this, the whole globe appears to the eye as a fairly uniform illuminated disc. It does not show the deep shadow formation upon the upper and lower diameters of the globe, as do the lamps hitherto in vogue. The impression on the eye is therefore far better. The hemispherical intensity of light relative to the lower diameter of the globe amounted to 2,772 candles, whence it follows that the specific consumption of the lamp was 0·196 watt.

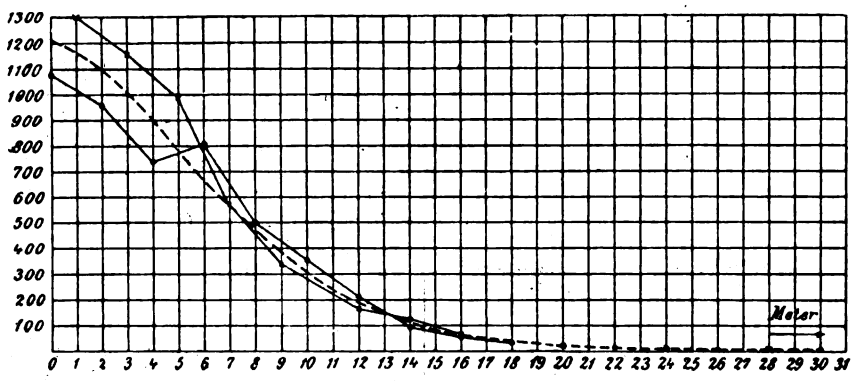

Fig. 3.

The hemispherical intensity of light of the lower diameter amounted to 2,772 candles, whence it follows that the specific consumption per candle-power was 0·196 watt. The second lamp was similar to the one now mounted on the Eiffel Tower, at a height of 95m. above the ground level. It contained four arcs, which were connected in two

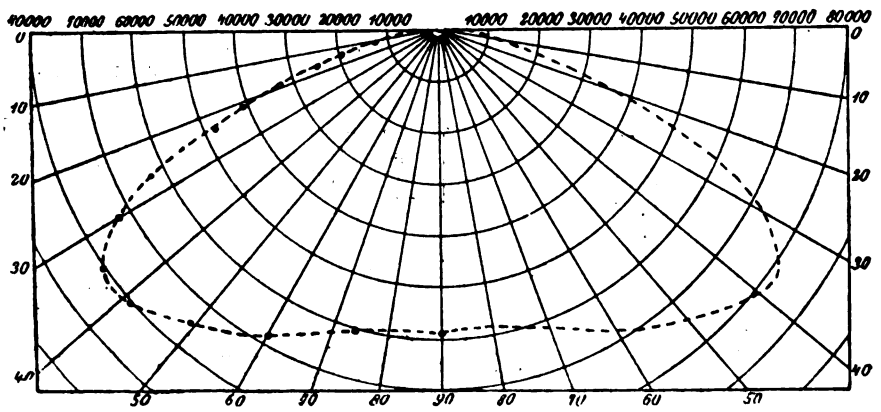

Fig. 4.

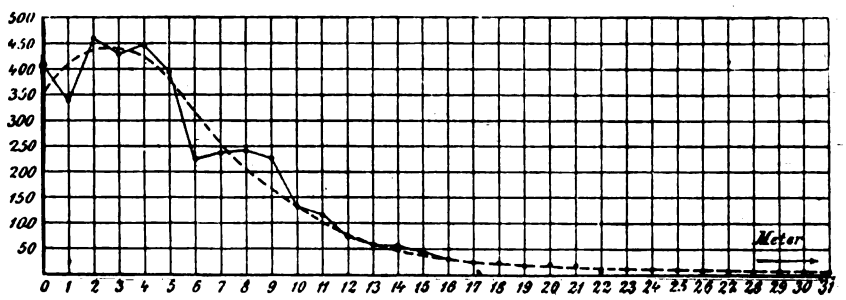

Fig. 5.

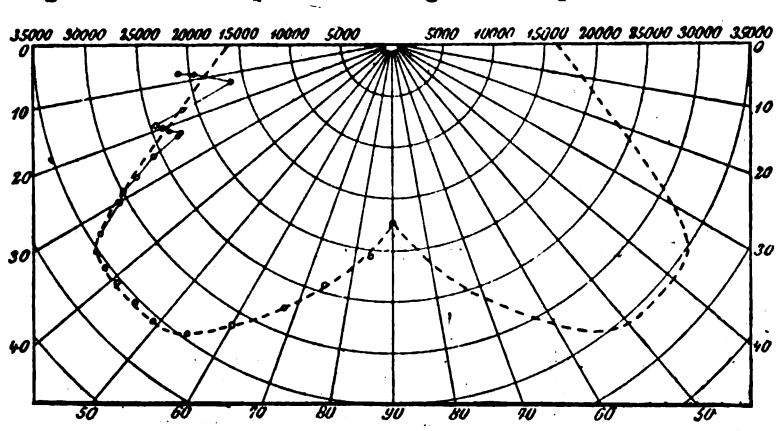

Fig. 6.

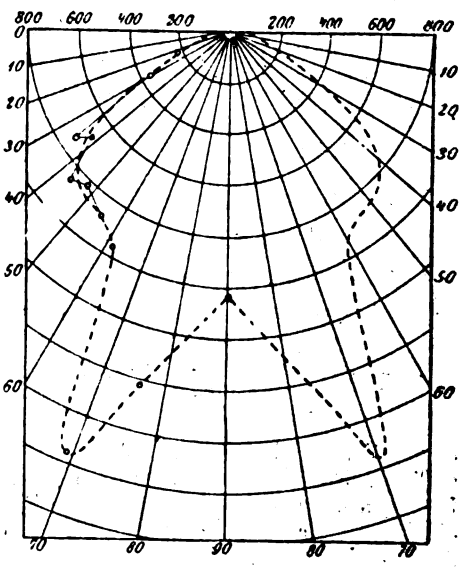

Fig. 7.

series groups when the measurements were taken, the lamp consuming 55·8 amperes at 89·3 volts terminal potential without a globe. Owing to the great intensity of the light obtained, the lamp could be examined only by night and in the open. It was suspended 8m. above ground, the measurement of the ground illumination being taken 1m. above the level. The results of the observations made are tabulated below (see Table III.).

TABLE III.—Large Continuous-Current Arc Lamp without Globe. 55·8 amperes × 89·3 volts = 4,980 watts.

* 1 metre = about 3ft. 3in.

The mean curve plotted from these data is shown in Fig. 3. From the values denoted by this curve the light intensities given by the lamp when placed at different angles to the horizontal were calculated (see Table IV.).

TABLE IV.—Large Continuous-Current Arc Lamp without Globe. 55·8 amperes × 89 3 volts = 4,980 watts.

Angle relative to the horizontal.	Intensity of light.
90°	59,290
74°	60,650
60° 10′	67,660
49° 20′	75,090
41° 10′	80,680
35°	80,530
30° 20′	72 620
26° 40′	63 330
23° 40′	47,110
21° 10′	41,110
19° 20′	32,550
16° 20′	24,460
14°	19 280
11° 40′	11,690

From the above values the curve (Fig. 4) showing the diffusion of light obtained with the lamp without a globe was plotted.

Corresponding to an angle of 37deg. the curve shows a maximum of 83,000 candles. The hemispherical intensity of light yielded by the integration of this curve amounts to 49,730 candles, whence it follows that with a consumption of 55·8 amperes × 89·3 volts = 4,980 watts the specific consumption of the lamp per candle-power obtained amounted to 0·1 watt.

Similar measurements were made with the lamp fitted with a globe, when the mean consumption of current amounted to 59 6 amperes at a mean terminal potential of 77 3 volts. The corresponding observations made under these modified conditions are given in Table V.

Fig. 5 shows the mean of the above values plotted in Curve 4, from which curve the diffusion of light corresponding to different angles of the lamp relative to the horizontal plane has been calculated. These latter values are given in Table VI., from which the curve shown in Fig. 6 has been plotted. From these figures it may be deduced that the hemispherical intensity of light obtained with a consumption of 4,610 watts amounts to 26,890 candles, which gives us a specific consumption of 0·17 of a watt.

20 10′	23,790
18 30′	24,710
17	21,750
15	19,610
13 10′	16,250
9 10′	19,530
8	21,540

It follows from the above data that the specific consumption of these two lamps, without globes, relative to the hemispherical intensity of light obtained, amounted, roughly, to 0·1 of a watt. The lowest value which it has been my experience to come across hitherto in connection with other lamps amounted to 0 3 of a watt, the average, according to my observations, being from 0·4 to 0·5 of a watt. Hence the specific consumption of the new lamp is at least one-third that of the types hitherto in use. In other words, three times the amount of light may be obtained with the same consumption of energy. This, in my opinion, constitutes a very important advance.

(To be continued.)

An Electrical Cure for Tuberculosis.—It transpired during the proceedings of the International Congress of Medicine, held at Paris, that a new treatment of tuberculosis had been discovered by a Frenchman (M. Franciaque Croth). The treatment is stated to consist in the direct transmission of antiseptics by means of static electricity, and seems to have given satisfactory results.

SOME NOTES ON DR. R. C. SHETTLE'S VIEW OF THE ULTIMATE NATURE OF ELECTRICITY.

BY SPENCER L. FLETCHER.

The view taken by Dr. R. C. Shettle of the ultimate nature of electricity is briefly as follows: (1) that electricity is a substance which probably consists of ether in a state of condensation; (2) that the individual atoms of matter are surrounded with atmospheres of condensed ether, which give to them their electrical properties and power of chemical combination.

From this it would follow that a positively-charged body is one which is more densely charged with condensed ether than a neutral body, a discharge being merely the liberation of this condensed ether. The view that electrical phenomena are to be ascribed to the agency of a substance is by no means foreign or contrary to the electrical science of to-day. "Clerk Maxwell proposed a theory of the relation between electromagnet phenomena and the phenomena of light, based upon the assumption that each of these are due to certain modes of motion in the all-pervading ether of space, the phenomena of electric currents and magnets being due to streams and whirls and other bodily movements in the substance of the ether, while light is due to vibrations to and fro in it."*

In a recent text-book for the University of London, the following statements occur: "When we electrify a body we effect some change in a very imperfectly known substance called electricity, which is associated with all matter, and which can be transferred from one body to another. When bodies possess their normal amount of electricity they are neutral, and when they possess more or less than that amount the excess or deficiency is called a charge. . . . When two dissimilar bodies are rubbed together all that takes place is a transfer of electricity from one to the other, so that one acquires an excess, the other an equal deficit."†

The view that the ether of space tends to condense upon the ultimate particles of ordinary matter is supported by no less an authority than Dr. Oliver Lodge ‡ The velocity of light in glass, as proved by the experiments of Foucault, is about two-thirds of the velocity in air (186,000 miles per second). To what must this decrease in velocity be ascribed? Glass itself transmits vibrations at only a few thousand feet per second, hence we must ascribe the transmission of the light rays which traverse the glass, not to the material of the glass itself, but to the ether within it. We arrive at the conclusion that the ether which occupies the interstices between the particles of the glass transmits light with only two-thirds of the velocity of light travelling in the ether of space.

From the analogy of sound, it is known that wave motion is retarded either by a decrease in the elasticity or by an increase in the density of the medium traversed. Dr. Lodge prefers the latter cause, ascribing the diminution in the velocity of light when traversing glass to a condensation of the ether within the substance of the glass itself. This means that each particle of the glass is surrounded by an atmosphere of ether which is of greater density than the ether of space. It appears that these ether atmospheres might be transferred from one particle to another according to much the same laws as those which govern the production of electric charges by friction. The source of electrification appears to be really contact of dissimilar substances, that is, substances which have a natural difference of potential, the motion of one substance over the other merely serving to renew the surfaces in contact.

By the natural potential of a substance is to be understood (according to the views stated at the head of this paper) the pressure of its contained ether. This will depend upon the tendency of the individual atoms of the substance to condense the ether of space around them, and this will presumably be different for the atoms of the different elements. Thus, if two *different* substances were brought into close contact so that their ethereal atmospheres might coalesce, it seems quite conceivable that after separation their charges of "bound ether" should be found to be shared in a proportion differing from that in which they existed before contact. One would lose exactly what the other gained, and thus positive and negative charges (representing excess and deficiency of electricity) would be produced in equal amounts. If the two substances were identical in every way, the affinities of their particles for ether would be equal, and there would be no tendency during contact for an *unequal* distribution of the ether charges. Hence, with two substances which are identically the same, no electrification results from bringing them into contact. This is exactly in accord with experiment.

If we conceive the ether atmospheres of the atoms to be endowed with any property resembling surface tension, it is possible to form a theory of chemical combination. For if two atoms were brought so near together that their ether atmospheres touched, these would coalesce like two drops of water, and since the ether atmospheres are attached to the atoms the two would be held together. In cases where the atomic atmospheres were large, the interstices of a molecule formed of such atoms would be completely filled with condensed ether, and a superabundance would accumulate outside. Such a molecule, or a mass of such molecules, would, according to the above views, be positively electrified—*i.e*, in a condition to communicate electricity (condensed ether) to a neutral body. Should this be a metallic wire, the excess of ether of the positive body would coalesce with the ether envelopes of the atoms of the wire at the point of contact, and from these pass on to others, thus establishing an actual flow of condensed ether along the wire until its potential and that of the original body were equalised.

Conversely, the constitution of a negative body would be such that its atomic interspaces were only partially filled with condensed ether. The atoms would have small envelopes, which would coalesce only at the points of contact with one another, leaving interspaces between. (*Note.*—It would at first appear that a positive body which is completely saturated with condensed ether would necessarily lose its cohesive property, because when the atomic interspaces were full, there would be no "capillary" surfaces of condensed ether to exert tension between the atoms. The conception of ethereal atomic envelopes possessing surface tension implies, however, that the condensed ether has an affinity for itself as well as for the atoms of matter, and this, upon the present hypothesis, is the ultimate force which holds the particles of a mass together.) The layer of condensed ether upon the surfaces of the atoms cannot be infinitely thin, or the amount condensed within a mass of glass would not sufficiently fill the interspaces in which the light travels to seriously affect its velocity. And since refraction (which is due to the retardation of the ray on entering the denser medium) takes place even in the upper regions of the atmosphere, it appears that the ether envelopes must fill a portion of the atomic and molecular interspaces, which is by no means negligible even in a rarefied gas.

Let us trace upon these hypotheses the action of an electrolytic cell containing, say, a solution of sodium chloride (NaCl). In a dilute solution, the ions, Na and Cl, it is now believed, are travelling about separately in the liquid, the Na endowed with a positive, the Cl with a negative electric charge. In other words, the Na is associated with an excess, the Cl with a deficiency of condensed ether. The two electrodes are also positive and negative in the same way. When an atom of Na, with its excess of "bound ether," comes into contact with the negative electrode, there is a transference of ether from the Na to the electrode. When an atom of Cl which is negative or deficient in ether comes in contact with the positive electrode which contains an excess, there is a transference of ether from the electrode to the Cl. Thus electricity enters the liquid by the positive and leaves it by the negative electrode. The ions appear only in the near neighbourhood of the electrodes, for until discharged by contact with them they appear to be chemically inert. The action of a voltaic or primary cell may be explained in a similar manner. When dry zinc and copper are brought together in air, the zinc is relatively

* Silvanus Thompson's "Lessons on Electricity and Magnetism," p. 359.

Digitized by Google

positive, and electricity flows from zinc to copper. If, however, the zinc and copper are partially immersed in a dilute acid and contact is made, the zinc is relatively negative, and the current flows (above the liquid) from copper to zinc. It appears that of two metals dipped into a corrosive liquid, that one becomes negative which is more easily corroded. Let the exciting liquid be dilute H_2SO_4; of this, the H is positive, the SO_4 group negative (as proved by their going respectively to the negative and positive electrodes in electrolysis). The SO_4 combines with the zinc, forming zinc sulphate, which dissolves in the liquid; hence positive zinc atoms are continually being subtracted from the zinc plate. Meanwhile the positive hydrogen atoms discharge their excess of ether into the copper plate, and thus a current is kept up along the external circuit from copper to zinc. In the case of contact of the dry metals, ether is transferred from copper to zinc, because the atoms of the positive zinc have the larger ethereal envelopes, the inter-atomic interstices of the zinc are quite full, and an excess of condensed ether resides upon the surface of mass.

The ether envelope theory also explains to some extent why transparent solids are non-conductors and conducting solids are opaque to light. In metals the condensed ether, or at least a portion of it, appears to be capable of flowing from atom to atom within the mass of the substance, maintaining a uniform pressure throughout like a gas dissolved in a liquid. This would seem inconsistent with the rigidity necessary for the transmission of the transverse vibrations of light. In glass, on the other hand, the condensed ether appears to possess this rigidity, to be more rigidly attached to the atoms and less mobile. Hence glass does not conduct. Water, if quite pure, behaves like glass—transmits light, but not electricity. To render it a conductor, a catalytic agent must be present, as a few drops of acid. Even then the transfer of condensed ether through the liquid is only accomplished by means of actual movements of the atoms. It is not real conduction, but electrolytic convection. It thus appears that the condensed ether in an opaque conductor, such as copper, possesses a certain amount of mobility, while in a transparent insulator, such as glass, it is more rigid and resembles a jelly.

TAUNTON ELECTRICITY WORKS.

On Wednesday afternoon, at the Taunton Corporation electricity works, the Mayoress (Mrs. W. A. Wren) formally set in motion the new electrical plant which has lately been installed to meet the extended use of electricity in the borough. The opportunity was taken to make a presentation to Alderman and Mrs. Potter, on behalf of the Council and inhabitants of Taunton, as a mark of the esteem in which the worthy alderman is held by his fellow-townsmen for the energy and ability he has displayed in presiding over the Electric Lighting Committee, and having succeeded in making its work so successful, both from the municipal and financial standpoint. The afternoon's proceedings commenced in the electrical machine-room, where a large and fashionable company had assembled, including the Mayor (Mr. Councillor W. A. Wren) and the Mayoress, Alderman W. and Mrs. Potter, Colonel Welby, M.P. for the borough, and other members of the Corporation.

Alderman POTTER sketched the growth of the electric light in Taunton, and referred to the new plant that had had to be placed in the works since the Corporation assumed control of the undertaking. Now the Corporation had added, at a cost of about £5,000, a new electrical steam pump for the purpose of pumping water into the boilers, and also an economiser. With regard to anticipated results, he might say in the month of June last, when the new plant was not running, the number of units generated were 18,606, and the consumption of coal was 90 tons. In the month of July, when the plant was worked, the units generated numbered 24,115, and the coal consumed was 77 tons.

The Mayoress then set the new plant in motion, and the assembly adjourned to a marquee erected in the yard outside, where refreshments were served.

The MAYOR then made the presentation, paying a high tribute to Alderman Potter for his work in connection with the committee, and which had been of so great advantage to the town.

Alderman POTTER, on behalf of his wife and himself, thanked them sincerely for their kind gift.

A vote of thanks was accorded the Mayoress on the proposition of Mr. VAN TROMP, seconded by Colonel WELBY, M.P., and the proceedings concluded with hearty cheers for Alderman and Mrs. Potter.

The presentation consisted of a very handsome silver tray embellished with flat chasing of old design, with richly fluted edges. In the centre are the arms of the borough, and the inscription "Presented, with a silver tea and coffee service, to Mrs. Potter, by the Council and burgesses of Taunton, in recognition of the services rendered by Alderman William Potter, J.P., as chairman of the Municipal Electric Lighting Committee, August 15th, 1900." The tea and coffee service is of solid silver, fluted in Chippendale style, and was supplied by Messrs. Franklin and Hare, jewellers, Fore-street. A casket of silver was presented to Mr. Alderman Potter, on the front of which are Mr. Potter's initials, in blue and red enamel, and on the reverse side the inscription "Presented to Alderman William Potter, J.P., with a copy of the resolution of the Taunton Town Council acknowledging services rendered by him as chairman of the Electric Lighting Committee, 15th August, 1900." On each side are columns, being representations of the borough mace. The cover is surmounted by the Taunton arms, and the casket stands on velvet. It was made by Messrs. Drayton and Sons, and is a beautiful specimen of silversmith's work. The illuminated address, which is excellently done, was the work of Mr. Burrow, engraver, of Bath-place.

FORTHCOMING EVENTS.

SATURDAY, AUG. 18.

Battersea Vestry.—At 3.30 p.m., foundation-stone laying of Lombard-road central electric station.

AUG. 18-25.

International Congress of Electricians at Paris.—

Aug. 18.—General meeting, at 10 a.m., at the Salle des Congrés, Pont de l'Alma. Reception. Division into sections, etc., tickets, etc. Afternoon, visit to the Exhibition.

Aug. 20.—Sectional meetings, commence at 9 a.m., 44, Rue des Rennes. Afternoon, visit to the electric installation of the Chemin de fer du Nord at La Chapelle.

Aug. 21.—Sectional meetings, 9 a.m., 44, Rue des Rennes. Afternoon, visit to Chantilly. Luncheon at 5. Return to Paris at 7.

Aug. 22.—Sectional meetings, 9 a.m., 44, Rue des Rennes. Afternoon, visit to the works of the Paris Compressed-Air Company, Quai Jemnapes, and to the works of the Metropolitan Railway.

Aug. 23.—Sectional meetings, 9 a.m., 44, Rue des Rennes. Afternoon, visit to the electric works of the Orleans Railway and the works of Moulineaux.

Aug. 24.—Sectional meetings, 9 a.m., 44, Rue des Rennes. Afternoon, meetings of sections not having finished their work.

Aug. 25.—Closing meeting, 9 a.m., 44, Rue des Rennes.

WEDNESDAY, AUG. 22.

Institution of Electrical Engineers.—Paris meeting; reception in the British Royal Pavilion in the Paris Exhibition, 5 to 7 p.m.

WEDNESDAY, SEPT. 5.

British Association.—Annual meeting at Bradford.

SEPT. 18 21.

Iron and Steel Institute.—Paris meeting, Sept. 18, 19, 20, and 21.

Sept. 17.—Secretaries' office opens at the Société d'Encouragement pour l'Industrie Nationale, 44, Rue de Rennes, at 3 p.m. 6 p.m., meeting of council at Mr. Henry Chapman's office, 10, Rue Laffitte.

Sept. 18.—9.30 a.m., reception of the president in the hall of the Société d'Encouragement; reading and discussion of papers. 2 p.m., visit to the Exhibition. 9 p.m., Soirée Musicale et Littéraire by the Comité des Forges de France.

Sept. 19.—9 30 a.m., general meeting in the hall of the Société d'Encouragement; reading and discussion of papers. 2 p.m., visit to the Exhibition. 7.30 p.m., the Institute entertains the Reception Committee at a banquet at the Hôtel Continental, Rue Castiglione.

Sept. 20.—10 a.m., visit to the exhibition at Vincennes (locomotives, railway plant, and machine tools). 8 p.m., Group A will start for the St. Chamond Works. 10 p.m., Group B will start for the Hayange Works.

Now Ready, Vol. XXV., bound in blue cloth, gold lettered, price 8s. 6d.

THOSE CRITICS.

We hold no brief for the Admiralty, nor shall we attempt to excuse departmental methods of procrastination, but we think that critics like Mr. Mr. F. T. Jane in discussing the late naval manœuvres might usefully occupy a little of their spare time in collecting information before they assume that all useful suggestions are pigeon-holed. In the *Chronicle* of Aug. 11, we find a heavy indictment against some unknown clerk for having shelved service suggestions relating to electric hoists on board men-of-war. Yet we are in a position to state that the question of employing electricity for various operations on board ship is not only not shelved, but is receiving careful consideration, and has for some time been under consideration. Hence the trouble is not in the absolute shelving, but in the lapse of time occupied in making up the minds of My Lords. It does not even come to this, for minds are made up. And yet much time is wasted before the final authoritative signature is given for the organisation or equipment of a special staff which must devote its sole attention to the problems arising from the use of electricity on board ship. The Admiralty officials must by this time have grown as used to the worrying of outsiders as an eel is to skinning, the result being that in the end the outsiders get their way. The waste of time, however, is alarming, as is the waste of money. Yet the system of irresponsibility continues. Outside opinion forced the introduction of breechloaders. Why? Because the conditions of the case all tend to the continuation of what exists. It is easy to go on in a stereotyped manner; it is troublesome to change for the better, especially when it is necessary to show that the change is for the better before it is made. A certain amount of experimental work is carried out, but there is no great meed of praise given to anyone who makes an improvement. Both services are permeated with a certain amount of cliqueism, so that ideas are not welcomed unless from the members of small coteries. Then usually the remuneration obtained for introducing something new to a Government department by a member of that department, is altogether out of proportion to that which would be obtained from outside sources. In other words, there is a lack of all incentive to introduce improvements. From the abstract point of view, it is wonderful that so much is done; yet *esprit de corps* counts for a good deal, and many men work hard to keep their particular department up to the mark. It is within the knowledge of many readers, for example, that years ago a number of experiments were made to use electric motors in the training of guns. The results of these experiments are fully known only in select professional circles, and we should not be surprised to see some critic condemning artillerymen for lack of appreciation in this phase of electrical work. It is to the credit of the naval authorities that so soon after the introduction of the dynamo and the modern arc and incandescent lamps, their value was seen and all ships fitted with them. The mere fact that this was so should go far to prove that no

Digitized by Google

clerk could really pigeon-hole a good suggestion for the increased use of electricity. Leaving aside this particular question for a far more important one, let us ask whether the majority of critics of public authorities ever considered the conditions surrounding the particular things they criticise. There is a fall of snow, always followed by howls because the various authorities do not keep the pavements and streets clear. There comes a week of hot weather, the streets are gritty and dusty, and the vestries and councils are anathematised because of the disgraceful state of the streets. There comes an unusual spell of dry weather, and, Oh! those water companies. The Admiralty builds and equips a ship. It is up-to-date to-day, but consider the remarks upon that ship and the Department because ten years hence it appears upon the list as one of the ships of the fleet. Really, according to the sentiments somewhat freely expressed of late, no ship belonging to the country ought to be reckoned a fighting unit after it has left the stocks. It is then out of date, its armament old, and altogether it is useless. Of course, if the world progresses, improvements come, and what is built is built, and in a measure is antiquated, but that is a thing which attaches itself to many of the things of this mundane life. Often there is much doubt as to what really is an improvement till the new departure had stood the test of trial; but whatever be the views held, one thing is certain—that the British first line of defence ought to be equipped with everything that is considered to be an improvement upon that which has gone before. Too much time should not be wasted before introducing improvements.

CORRESPONDENCE

"One man's word is no man's word,
Justice needs that both be heard."

CONDUIT v. TROLLEY.

SIR,—In the letter by J. Clifton Robinson entitled "The Case for the Trolley Tram in London," quoted from the *Daily Mail*, which appeared in your issue of the 10th, I trust we may see the commencement of a real vigorous campaign against the *folly* of the proposals of the London County Council (under the advice, it is understood, of Prof. Kennedy) to saddle London with the expense of a conduit system.

I will only ask you to admit one remark on the subject of the exaggerated unsightliness of the overhead trolley construction, which is, that her Majesty the Queen of these realms, during the splendid reception she had in Dublin last March, passed under 10 miles of trolley wires, the supports of which, instead of being in the way, gave an opportunity for an unprecedented beauty of floral decoration which would otherwise have been impossible.—Yours, etc., C. E. WEBBER (Major-General).

THE JANDUS ARC LAMP AND ELECTRIC COMPANY, LIMITED, v. WILLIAM JONES DAVY.

SIR,—In reference to the note appearing in your recent issue *re* the discontinuance of our action against William Jones Davy, we must ask you, in justice to the Jandus Arc Lamp and Electric Company, Limited, and to our many licensees, to state that proceedings in the nature of a test action upon the Jandus patents are now pending, in which we are advised that (as in the recent Johnson and Phillips action) we shall have a successful issue.

We shall then deal with the smaller infringers as we did with those licensees who, to their own detriment, elected to join hands with Messrs. Johnson and Phillips in disputing our rights under our licenses.—Yours, etc.,

A. A. GILLIES, Secretary.

(For the Jandus Arc Lamp and Electric Company, Limited.)

VISIT OF THE A.I.E.E.

The weather "did us proud" during the last few days, and consequently the excursion of the American and English electrical engineers on Sunday to Henley proved an extremely enjoyable outing. Monday was given over to business. The morning was reserved for visits of such of the members of the A.I.E.E. as chose to avail themselves of the privilege of going through the Board of Trade laboratories and the telegraph department of the General Post Office. In the afternoon a fair number assembled at the platform of the Shepherd's Bush Station of the Central London Railway, where they were taken in tow by the indefatigable secretary of the Institution, Mr. MacMillan. A few minutes' walk brought the party to the spacious enclosure of the company's generating station and workshops. The engineer of the company, Mr. T. Stevens, then explained the wonders of the place. The yard is connected with the sidings of the Great Northern and Great Western Railways, and contains a number of large buildings. The extreme loftiness and vast size of the workshops failed not to impress the visitors. A dozen or more motors which were laying about, casually, as it were, served well to illustrate the magnitude of the concern, while the inner "works" of others in various stages of progress showed that if not everything, at least a good deal of the work is done on the spot. The easy working, starting, and stopping of one of the motors upon which the visitors were allowed to travel through the yard, was greatly admired. Here it was where the kodakers took their opportunity and their snapshots. The engine-house came next, a building remarkably free from noise—there were three large machines running at the time—but its temperature of about 105deg. did not favourably compare with the atmosphere just left in the 2d. tube. We noticed an admirable cooling tower at the end of the building, and wondered why a fan to ventilate the engine-room had not been connected with it. The boiler-room was really much cooler. The elaborate condensing apparatus, scrapers, etc., alone repaid for the visit. Everywhere the same vastness of space prevailed. After leaving the works the party were taken down the 2d. tube again, without disbursement of the customary obolus, however, as the general manager, Mr. Cunningham, had taken charge of them, and the Bond-street Station, which is not yet open to the general public, was especially open for the occasion. The visitors expressed themselves greatly pleased with the company's decision not to disfigure the beautiful white glazed walls of the tunnels with advertisements. Mr. R. K. Gray took charge of those who wished to visit the sub-station at the Marble Arch, and both groups then spent some time at the large Davies-street station of the Westminster Electric Lighting Company.

On Monday evening the Institution had a dinner in honour of the members of the American Institute who were over on their road to the Paris Exhibition congress. The dinner was held at the Prince's Restaurant, than which no better place could have been chosen. It was largely attended, considering that London is out of season, and Prof. Perry made an excellent chairman. The speeches, both from members on our own side and from those coming over the Atlantic, were far above the average. Of course, we know that Americans are born orators, and it must have been due to the recent rubbing of shoulders that our own representatives rose to the occasion. It is not necessary to report the speeches, as they were all of a social character, though Prof. Perry commenced with claiming everybody as compatriots, even though they were accidentally born in some other land; and we really think that ere the end of the evening, every lady and gentleman

Digitized by Google

in the assemblage was ready to swear eternal sister and brotherhood. It was a happy gathering, admirably conceived and carried out, and will form a red-letter day to all who were present.

On Tuesday morning about 20 members of both the American and English institutions met at Victoria, including Mr. Carl Hering and Prof. Perry (the presidents), Mr. Pope and Mr. MacMillan (the secretaries), Major-General Webber, etc. At Chatham, which was reached at 11 a.m., a drag with four fine greys stood in waiting, and soon brought the party up to the dock gates, where they found a very large inscription: "Bring no matches into this dockyard," much to the concern of the smokers, who were not in a minority. Here they were met by Major Carr, the chief instructor of the Electrical School of Military Engineering, who proved an inexhaustible mine of information during the rest of the day. Further on the Admiral-Superintendent Swinton C. Holland made his appearance and welcomed the visitors. Presently a funny little engine came along with two large-sized trunks behind it, into which all were stowed away somehow in order to proceed on what seemed a 12in. gauge of rail through the yard. It is said of the "Black Maria" that its horses are so swift that they will take you in half an hour where it may take you six months to get back again. That funny little engine played a very similar joke. It took you along for about five minutes, and you had a walk back of about two hours afterwards. To see Chatham Dockyard sufficiently, two or three hours are nothing. Mr. Reid, C.E., joined the party, and explained the details of the ships now in the course of construction, and also of various appliances to be found in the workshops. There was the "Albemarle," laid down on Jan. 8 this year, in the slip, and showing already considerable signs of progress; further on the "Venerable," in the dry dock, just having the armour-plates put on (this ship was laid down on Jan. 2, 1899); and the "Irresistible," in the basin, about a year older, and nearly completed. There was much that was interesting, but little that was new, in the large workshops, barring, perhaps, the searchlights, a number of practical portable electric motors of various sizes, which can be coupled to a flexible shaft wherever power is required, and the clever contrivance for firing off torpedoes, consisting of two electromagnets, by means of which a metal ball is released suddenly. This, by means of a contact box, frees a circuit connected with a shaft, and thus brings an independent battery into play, by means of which the tube is fired. After visiting the boiler-rooms, where the galvanic baths were seen in operation, came the long, long tramp past dozens of her Majesty's ships, just returned from the manœuvres, up a steep hill into the schools. They are lofty and airy, and contain the appliances for the high theoretical and practical teaching for which they serve. The visitors all declared that they had never seen such a beautiful projecting lantern as the one shown by the instructing officers in one of the school-rooms. Power is laid on to the tables, thus giving every facility for demonstration. A number of very powerful searchlights, also serving for instruction purposes, were shown next. Automatic arc lamps only are now used. The school is divided into telegraph and electric light classes.

The work now being ended the play began, and soon the officers' quarters were reached. Here Major-General Sir Thomas Fraser, K.C.B., C.M.G., R.E., received the visitors and headed the table at the excellent and most enjoyable luncheon which followed. The mess plate and the throne and cushions of the late Emperor of China came in for their share of admiration during smoking time. In answer to an intimation to "come into the garden," the visitors passed through the Crimean arch on to the lawn of the commandant's house, and paid their respects to Lady Fraser. The "At home" took the shape of a garden party, where a long programme of music by the band of H.M. Royal Engineers, under the leadership of Lieutenant J. Sommer, R.E., proved the attraction on one end of the lawn, while the other end, near the refreshment tent, was not exactly quite deserted. However, five o'clock soon came along, and with it the coach, the train and the return journey.

On Wednesday morning the visitors, who expressed themselves vastly pleased with their reception, left for Paris.

CONDUIT v. TROLLEY.

Under the above heading we published an article in our last issue from the pen of Mr. J. Clifton Robinson, C.E., which appeared in the *Daily Mail* of Wednesday, Aug. 8. In its impression of the 10th inst. the same paper contained an interview with Mr. J. Allen Baker, L.C.C., which may be taken as representing the views of the other side—that is to say, the converts to the conduit system, the policy of the London County Council in adopting which Mr. Clifton Robinson so strongly opposes. The following remarks in defence of this policy elicited from Mr. Allen Baker during the course of the interview in question should therefore prove interesting:

"London is still asleep to the importance of tramways in modern life and the immense saving which is coming to us with the adoption of electric traction. On the New York conduit system, where, of course, labour and other expenses are much higher than in London, the working cost has been reduced to 5d. per car mile. At least an equal result might be anticipated for London. But assuming the working cost of electric traction to be 6d. per car mile (a figure that has been justified by trolley experience in various cities in the United Kingdom) the margin of profit on the present mileage would then, without any increase of car mile earnings, amount to the sum of £750,000.

"Loss of Time in Money.

"Thanks to the slowness of horse traction, at a low estimate an average of at least a quarter of an hour is lost by each passenger daily. If you reckon the time of the people as worth only the minimum labour wage of 6d. an hour, this loss of time even on the present traffic mileage might be valued at 2¼ millions a year, which will be saved when electric traction comes—an item which, of course, would be enormously increased by the natural development and extension of the system. The London County Council is now doing its best to ensure that we shall have a tramway system worthy the capital of this Empire. It is getting a Bill through Parliament which will enable it to transform all the present lines of horse traction to electric, and as early as possible it will lay down a conduit line from Westminster to Tooting. The Highways Committee of the Council is anxious to obtain many necessary extensions both in the centre of London and in the suburbs. But here it is frequently blocked by the vestries. Although the County Council is the supreme tramway authority in London, the vestries are the road authorities. By the present defective state of the law, the County Council cannot even be heard in Parliament in favour of extensions or new tramways until the consent of the vestries is obtained.

"Against the Trolley.

"So far as the Council is concerned, there is now no controversy about the method of traction to be used. We have decided against the electric trolley, and in favour of either the conduit or surface contact. This decision has not been taken without most careful consideration of all the facts bearing on the matter. We are not faddists, tied down to any one plan. Our one desire is to give London the best. I saw the conduit at work in Washington and New York, and I must say I was convinced it met the requirements of a large and crowded metropolis like London much better than any other system which we have before us and which has been practically tested. Before I had opportunity of seeing the actual returns of working expenses, I felt sure from my knowledge as an engineer that the conduit should be cheaper to operate (leaving the initial cost of construction out of the question) than the trolley. In the trolley there must be a certain loss of electricity in working, which, in a properly-constructed conduit where both currents are conveyed by insulated bars, is avoided. On the trolley you have the sparking of the wheels wherever any rubbish or dust comes between them and the rails. This is unsightly and frightens horses, besides causing a waste of electric power. The trolley needs constant repair, in mending broken wires, tightening slack wires, stays, guys, and the like. The ugly repair

Digitized by Google

van is constantly seen on the road wherever there is an overhead wire system.

"THE ÆSTHETIC OBJECTION.

"There are two other disadvantages of the trolley which must be mentioned, though I have no wish to dwell on them too much. There is the æsthetic objection to the unsightliness of overhead wires. No doubt people quickly become accustomed to these, but you cannot say that they add to the beauty of any place. In London the disadvantage of overhead wires would be especially felt. Owing to the necessity of guarding observatories and other centres of scientific observation, and for the avoidance of electrolysis in street mains, it has been decided by the Board of Trade that any overhead lines in London must have double return wires, or that there must be four rows of overhead wires for every double track. You would have eight wires across the street where lines crossed. In addition, of course, there would be the staying wires. At such a place as the Elephant and Castle, where half a dozen lines met, the street would be obscured by the maze of overhead wires. Notwithstanding all that has been done to make them safe, there is some danger in having so many live electric wires in the streets. You can find case after case in recent years where men and horses have been electrocuted by such wires breaking and falling.

"CONDUIT CHEAPER THAN TROLLEY.

"I said that I was convinced theoretically that the conduit ought to be cheaper to work than the trolley. I have since been able to obtain the actual working figures of the Metropolitan Street Railway Company of New York, the company which there owns the conduit lines. This company runs both conduit cars, cable, and horse cars. It finds that the operating expenses of its horse and cable cars are each about 8½d. a mile, while its conduit cars only cost 5d. per mile. In Chicago they have the horse, cable, and trolley running at the same time. There they find that while the cable costs 5½d. per mile, the trolley costs 6¼d. In other words, the conduit in both cases is cheaper than its competitors. It is urged against the conduit that it is very costly to construct, and that it involves great disturbance of the streets. It is admittedly more expensive to lay down than the trolley, but not nearly so much so as many try to make out. The cost of a conduit line, apart from the removal of street mains, may be about 20 per cent. more than a trolley line. Where the trolley line under Board of Trade conditions would cost about £10,000 per mile of single track, the conduit would cost a little over £12,000. But this initial extra cost should be fully compensated for by the economy in working expenses.

"DIFFICULTIES CAN BE OVERCOME.

"Much stress has been laid on the removal of mains that would be necessary in building a conduit line in Central London. The whole of this problem was carefully considered by the County Council before deciding in favour of the conduit. In construction it will not be necessary to go more than about 2ft. 6in. deep for the foundations and iron chamber of the conduit. It should seldom be necessary to move any pipes, save at crossings, and we are obtaining such powers as will enable us to do such removal cheaply and quickly. It is possible to begin and finish each section of a street in three or four weeks. In building conduits in New York the tramway company took from 14 to 28 days over each section. What we aim at is to give to London a tramway service worthy of the Metropolis of the Empire, uniting North and South and East and West London under one great system, giving to the millions of our workers the benefits of a rapid, comfortable, and cheap means of transit from centre to suburb, or to those whose homes are in the crowded central districts, to park and open space outside. Most of the objections raised to the conduit system have arisen from personal interest or from misapprehension caused by imperfect knowledge. It is naturally to the interests of manufacturers of electrical appliances to advocate a system where the main expenditure goes on electric plant, rather than one where the greater part of the money goes on the permanent roadway. But the Highways Committee of the County Council is content in this matter to leave the verdict to experience."

THE ELECTRICAL ENGINEERS' CORPS IN SOUTH AFRICA.

The following is an extract from a report received from Major Crompton, dated July 17 and 18, 1900, showing where the officers, non-commissioned officers, and men of the corps were at work on those dates:

Of the six who were taken prisoners, two escaped and the other four were released. Lieutenant Pott is reported to be convalescent, and to be returning home. Second-Lieutenant Bigge, who was wounded, has returned to duty. Of those in hospital, Sapper Dalton is reported to be doing well; Sapper Arundel is convalescent, and owes his life to splendid nursing; Sapper Brander is convalescent. No information is given as to the condition of the others reported in hospital. The men have been at work: (1) as electric engineers fitting-up and repairing electric light and power plant; (2) searchlight men; (3) arc-light men for working parties; (4) on telephone light lines; (5) as army telegraphists; (6) as railway telegraphists; (7) as Royal Engineers' working parties on crib and trestle reconstruction railway bridges; (8) as a fighting unit. Major Crompton reports that they have done well in each branch. Major Crompton has requested me to remember him to all the officers and the corps as a whole, and hopes that what has been done in Africa will help the corps both as regards its prestige and future popularity, and he feels proud to have had command of such a thorough good lot of men.

(Signed) R. S. ERSKINE, Major.
Officer Commanding Electrical Engineers, R E. (Vols.).

Major R. E. B. Crompton, Headquarters, Pretoria.
Captain F. L. Lloyd, Headquarters, Pretoria.
Captain A. Bain, Railway Telegraph, Elandsfontein.
Captain H. M. Leaf, Headquarters, Pretoria.
Lieutenant J. F. O'Shaughnessy, Railway Telegraph, Elandsfontein.
Lieutenant A. H. Pott (enteric), Viljoensdrift.
Second-Lieutenant J. H. Stubbs, Army Telegraph, Kroonstadt.
Second-Lieutenant H. H. Bigge (wounded), Hospital, Johannesburg.
Second-Lieutenant F. Powell Williams, Headquarters, Pretoria.
16721 Sergeant-Major G. A. Brown, Headquarters, Pretoria.
6263 C.-S.-M. E. Rorke, Headquarters, Pretoria.
21109 Sergeant C. T. Ruse, Headquarters, Pretoria.
6166 Sergeant J. H. S. Phillips, Headquarters, Pretoria.
6171 Sergeant W. S. Entwistle, Railway Telegraph, Elandsfontein.
6193 Sergeant J. H. Brown, Headquarters, Pretoria.
6173 Corporal H. Bicker-Carter, in charge detachment, Bloemfontein.
6192 Corporal A. H. Graham, Headquarters, Pretoria.
6191 Corporal A. Charlton (prisoner believed; sent back).
6179 Corporal W. Dalton (enteric), Kroonstadt.
6206 Second-Corporal J. H. Stone, Railway Telegraph, Elandsfontein (reported hospital).
6264 Second-Corporal E. M. Sellon (released).
6183 Sapper H. R. Allen, Headquarters, Pretoria.
6271 Sapper F. D. Arundel (enteric), Bloemfontein.
6199 Sapper H. Bertram, Bloemfontein.
6169 Sapper S. M. Bowrey, Headquarters, Pretoria.
6196 Sapper R. H. Brander (sick, dysentery), Bloemfontein.
6210 Sapper G. Charlton (escaped).
6194 Sapper D. F. Colson (released).
6180 Sapper W. C. Cook (sick, on orderly duty to Lieutenant Pott), Viljoensdrift.
6187 Sapper M. N. Crawford, Bloemfontein.
6267 Sapper H. F. Claxton, Headquarters, Pretoria.
6269 Sapper W. G. Carter, Headquarters, Pretoria.

CITY AND GUILDS OF LONDON INSTITUTE.

The diploma of "Associate of the City and Guilds Institute" (A.C.G.I.) has been conferred upon the following matriculated students, who have completed a full course of study at the institute's Central Technical College, and have satisfactorily passed the examinations in the several courses:

Civil and Mechanical Engineering.—J. M. Bowrey (Jamaica Government Scholar), A. Bromley-Smith (London County Council Intermediate Scholar), J. F. Butler (John Samuel Scholar), A. H. Clark, W. H. C. Clay, R. H. Collins (Mitchell Scholar), A. E. Culley, F. Dennis (London County Council Intermediate Scholar), B. M. Duke, R. Freeman (Siemens Scholar), C. W. Jones (Haberdashers' Exhibitioner), A. J. Knight, S. Leslie, A. J. Munro (Fishmongers' Exhibitioner), F. Osbourn (London County Council Intermediate Scholar), W. J. Rusdell (Alleyn Scholar), J. W. M. Topley (Institute's Scholar), H. B. Unwin, J. A. Wickham.

Electrical Engineering.—M.V. Allen, F. C. N. Bergh (Durham County Council Exhibitioner), J. H. Brown, H. Berge, H. H. Crockford, B.A., W. A. Del Mar, E. Fawssett, P. Good, S. Gowan, H. J. Humphreys, A. P. Hutchinson, T. L. James (Institute's Scholar), H. L. E. Kennard, W. J. Line, F. G. Maunde-Thompson, D. H. Montgomerie, J. A. Parker (Clothworkers' Scholar), H. J. Thomson (David Salomons Scholar), M. A. Wood.

Applied Chemistry.—E. J. Denney, P. V. Dupré, J. A. Fortesquieu (London County Council Scholar), J. B. Gall (Mitchell Scholar), T. H. Page (London County Council Intermediate Scholar), T. R. Starkey, J. H. West (Institute's Scholar), W. B. Woodbridge.

Certificates have been awarded to the following students:

Students who have taken the regular course of instruction (including the third year course) at the Institute's Central Technical College for one or more sessions:

Civil and Mechanical Engineering.—E. S. Allsup (second class), P. L. Bowers (first class), F. G. G. Ford (first class), C. T. Gardner (second class), F. C. Henriques (second class), E. D. Kibble (first class).

Electrical Engineering.—H. R. Carson (first class), C. L. Faunthorpe (first class), R. G. Kindersley (first class), R. V. Lynn (first class), G. M. Newbery (first class), C. E. Newton (first class), W. G. Shee (second class), C. E. Vines (first class).

Chemistry.—J. R. G. Hopper (Surrey County Council Scholar) (first class).

Students who have taken the regular course of instruction (not including the third year course) at the institute's Central Technical College for one or more sessions:

Civil and Mechanical Engineering.—F. D. Arundel (first class), R. J. Francis (first class), E. J. W. Peck (first class), L. Pryce (second class), H. R. Scarlett (second class), J. B. W. Stroud (second class), F. H. Wroughton (second class).

Electrical Engineering.—W. G. Carter (first class), A. C. Stock (second class), J. H. Stone (first class).

Chemistry.—R. Blenkinsop (second class).

Students who have regularly attended a complete course of instruction for day students (extending over a period of two years for mechanical and electrical engineering students and three years for chemical students) at the institute's technical college, Finsbury, and have satisfactorily passed the several class examinations:

Mechanical Engineering.—D. A. Brown (London County Council Intermediate Scholar), F. M. Green, J. A. Merrett, S. S. Nevill, A. H. Roberts (London County Council Intermediate Scholar), S. W. Sims (London County Council Intermediate Scholar), P. Spalding, P. W. Warwick, A. C. Whish.

Electrical Engineering.—A. W. Bartlett (London County Council Intermediate Scholar), F. C. Baumann, G. Bish, J. Eustace, H. Frodsham, J. A. Gilfillan, E. C. Handcock, L. J. B. Hannan, J. T. Haynes, A. S. Herbert, F. I. Hiss, T. C. Hunt, W. J. Jeffery, C. R. Kemp, A. A. Kift, T. H. Langford, P. A. Laubach (London County Council Intermediate Scholar), W. U. Lonnon, B. H. Morphy (London County Council Intermediate Scholar), L. Murphy (London County Council Intermediate Scholar), M. Parker, R. L. Pearson, F. Pritchard (London County Council Intermediate Scholar), P. J. Robinson, F. R. C. Rouse (London County Council Intermediate Scholar), G. B. D. C. Saw, H. Seward, T. H. Vigor (London County Council Intermediate Scholar), W. S. Wright.

Technical Chemistry.—M. B. Blackler (London County Council Intermediate Scholar), J. W. G. Brooker, H. E. Course (London County Council Intermediate Scholar), J. V. Eyre, W. A. Handcock, H. Harding (London County Council Intermediate Scholar), J. Harris (London County Council Intermediate Scholar), F. T. Harry (London County Council Intermediate Scholar), E. Horton (London County Council Intermediate Scholar), H. E. Hoskin (London County Council Intermediate Scholar), A. Landau, W. J. A. Parish (London County Council Intermediate Scholar), W. Partridge, S. O. Richmond, T. R. B. Stevens, G. W. G. Tatham, T. C. Thomas, F. P. Whitaker (London County Council Intermediate Scholar).

Students who have taken a special course of instruction in one or more departments at the institute's Central Technical College for at least one session:

E. Brown, electrical engineering; W. L. Browne, civil and mechanical engineering; T. F. Burton, electrical engineering, chemistry, and mathematics; W. D. B. Duddell, electrical engineering; J. Gana, civil and mechanical engineering and mathematics; J. Lehmann, electrical engineering; H. E. Lyddon; civil and mechanical engineering, mathematics, and chemistry; L. L. Mercer, civil and mechanical engineering; H. Reé, electrical engineering; A. Rogers, civil and mechanical engineering and mathematics; S. de Stefani, electrical engineering; C. O. Thomas, civil and mechanical engineering and electrical engineering.

CATALOGUES AND OTHER PUBLICATIONS RECEIVED.

We have to acknowledge the receipt of several catalogues and leaflets from the General Electric Company, Limited. One of the former and larger publications deals with electric bells in a most thorough and comprehensive manner. Previous additions of this catalogue have rendered its general features familiar to the trade, but, of course, there have been many additions made in the revised issue, and what is, perhaps, more important, the prices of the thousand and one articles enumerated have been largely reduced in order, we are told, to enable the firm to keep pace with outside competition. At the same time, none of the reductions have been effected at the expense of quality. Personally, we happen to be acquainted with the company's huge factory in Salford, Manchester, where an establishment of over 1,000 hands is employed, as also with the methods in vogue there which enable high-class articles to be turned out at moderate prices. In their essential details of construction the cheaper class of goods manufactured by the firm are not inferior to the higher-priced articles of similar type, the relative cheapness being accounted for by economy in superfluous finish. An ammeter, for instance, fitted into a roughly-finished case should not give less satisfactory results than one placed in a highly-polished case, provided the internal workmanship is equal. In fact, for all practical purposes the instruments will possess equal value. Nor will an electric bell be necessarily less efficient because it is provided with a stained wood case instead of one of polished walnut. It is economy, then, effected in the less essential features of the apparatus which enables the General Electric Company to place reliable goods on the market at popular prices. We would not, however, give the impression that the cheaper-grade articles offered by the firm are of very rough finish; on the contrary, their finish is good enough for all ordinary purposes, the difference in appearance from the higher-classed articles being scarcely apparent. Labour-saving machinery also plays an important *rôle* in effecting economy of production at the Salford works, the firm having shown itself singularly alive to the possibilities of such apparatus. But to return to the catalogue. The compilers have succeeded well in their efforts to provide lucid descriptions and to arrange the numerous illustrations in a clear manner. The accompanying illustrations (Figs. 1 and 2), taken from the catalogue, show respectively a two-noted "motor" movement bell, which may be recommended for effect, and a compact ventilating outfit consisting of an

Digitized by Google

"Edison" iron-clad motor with an "Edison-Leyland" battery complete. The catalogue further includes many hundreds of illustrations of electric bells, indicators, and accessories, etc. Appended to the catalogue will also be found what constitutes a thorough manual of electric bell fitting, which cannot fail to be of great use to the technical and practical electric bell fitter,

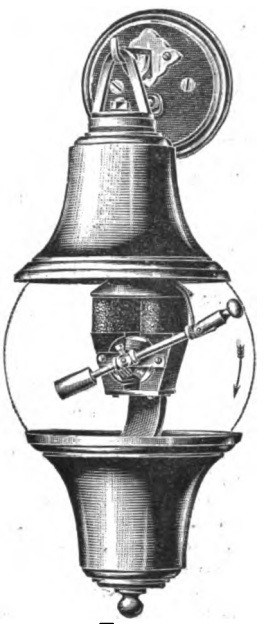

FIG. 1.

comprising as it does a complete set of diagrams showing connections for bell indicator circuits, etc., the outcome of many years' practical experience with this class of work. A copy of the same firm's new catalogue of wires, cables, conduits, casings, and wiring sundries has also reached us.

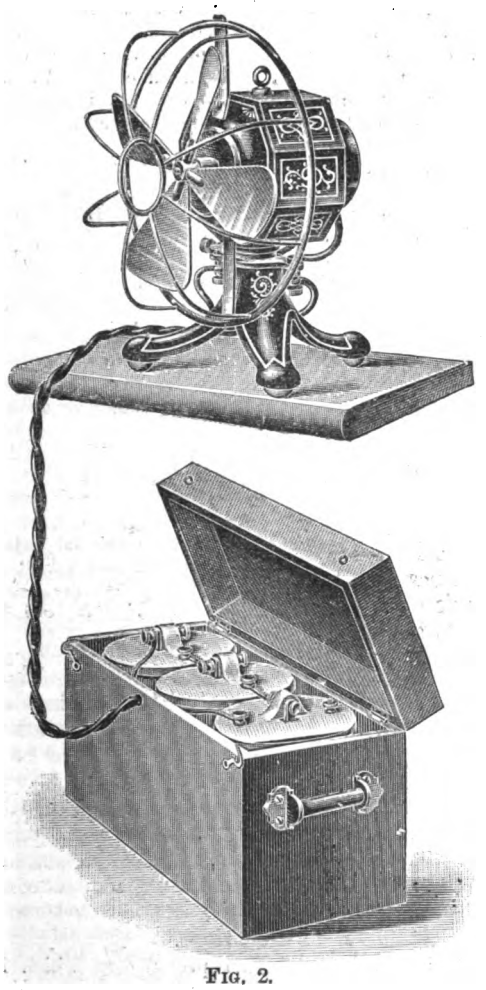

FIG. 2.

This is likewise a comprehensive volume of its kind, and represents the tenth edition of the firm's catalogue dealing with the above lines, although it is the first occasion upon which they have compiled a special list for wires, etc., independent of any other lighting or bell material. Wires and cables for electric light, bell, and telephone work are dealt with exhaustively, whilst in most useful rotation follow prices and particulars for casings, conduits, insulators, wiring accessories, and tools, the object of the special arrangement adopted being, we understand, to facilitate reference for purchasers of these particular classes of material. Another point of note is the section dealing with twin paper-insulated lead-covered wires and cables for house wiring, and also twin vulcanised wires and cables, which are now in great demand for conduit systems. The various systems of conduit are also very clearly enumerated in the list, more especially the firm's "Union" system, which, we understand, is finding extensive adoption. A novel feature with regard to conduits is the patent adapter block, shown on p. 232, for joining conduit to casing in a neat and workmanlike manner. Various new types of high-tension insulators are also shown, which, together with the other interesting features enumerated, should constitute the catalogue of considerable use to the trade, to whom copies are offered free on application to the head office of the General Electric Company, Limited, Queen Victoria-street, London, E.C.

Of less bulk is the same firm's new list of multipolar motors and lift controllers, briefly acknowledged in our issue of last week. These lists are intended for incorporation with the General Electric Company's big catalogue, a new edition of which is in course of preparation, and consulting engineers and contractors are invited to apply for copies in order to render the present list up to date. The same remarks apply to several leaflets dealing with new accessories, etc., just issued by the same firm.

Pamphlet No. 71 of the British Thomson-Houston Company, Limited, describes the Thomson tramway and portable recording wattmeters, already noted by us in our account of the Railways and Tramways Exhibition at Islington last month. Wastefulness of current on electric tramcars, due to the carelessness of the motormen, has been recognised by tramway managers as of serious importance, and the most effective method of checking it has thus far proved to be by installing in each car a tramway meter. Many tramway managers agree that the average waste due to carelessness of the motorman amounts to 20 per cent. or more of all the energy consumed. From tests recently made, as much as 25 to 30 per cent. difference has been found among motormen running the same car under almost exactly similar conditions. When proper records of the cars and of the motormen are kept, a saving of from 10 to 20 per cent. should be effected, and in some cases as high as 25 per cent. The profit from such economy is twofold. It saves, first, the cost of coal and water necessary to generate one-tenth to one-fifth of the total energy output of the station; second, it increases receipts by increasing car capacity in direct ratio of power saved, without enlarging the station. The electrical and mechanical construction of the street railway meter is of that extreme simplicity that ensures long life, great accuracy, and little liability to get out of order. It is especially designed to operate under the most severe conditions found in the electrical tramway service of to-day. Pamphlet No. 70 deals with magnetic blow-out lightning arresters for direct current. The function of lightning arresters in an electric installation is to relieve the conductors of any excessive electric potential differences that may exist between them and the earth, and at the same time to prevent the current of the generators following in the track of an electric discharge from conductor to ground. In the construction of lightning arresters for light and power circuits it is necessary, in order to afford protection to the circuit on which it is installed, that the path of the lightning discharge through the arrester provides a perfectly free path to the ground. A second consideration arises from the fact that electric circuits, however carefully insulated, are likely to have leaks to ground, especially in rainy weather, when thunderstorms are most frequent; the circuits usually must be equipped with several arresters to protect different sections of the line, and discharges may take place from the line to earth conductors simultaneously at several points. Under these conditions the generator current, though not of sufficient E.M.F. to start an arc across the air-gap of the arrester, is capable of maintaining one or several arcs started by a lightning discharge. These arcs, if continued, would not only destroy the arrester, but would in many cases permit such an excessive flow of current as to overload or destroy the generator or other apparatus. Eight types of the arresters are described in the pamphlet; these are adapted each for its special use, and should not be employed for circuits other than those specified.

From the British Westinghouse Electric and Manufacturing Company, Limited, we have received two interesting publications which cannot be classed as catalogues. One of these, entitled "Polyphase Induction Motors," describes various polyphase motors of Westinghouse manufacture in a very lucid manner, the text, as also the numerous illustrations, being well above average merit. Those wishing to learn something relative to the characteristic and general features of polyphase motors could not do better than obtain a copy of the booklet to add to their collection of similar publications by the firm in question dealing with other subjects. The approximate dimensions given for each type enhance the practical value of the publication. The other publication

Digitized by Google

received from the Westinghouse Company's publishing department is entitled "Electric Power," and illustrates the application of Westinghouse motors for various purposes. The illustrations cover a very wide range, and serve to indicate how electricity is making its way into practically every field where power is required. Brief references are given in four languages to each illustration, which, it only remains to say, are uniformly excellent, and should serve a useful purpose.

Messrs. John Spencer, Limited, Globe Tube and Engineering Works, Wednesbury, Staffordshire, have issued a very complete revised price-list of wrought-iron and steel tubes and fittings, etc., of every description for gas, water, steam, and hydraulic purposes; boiler tubes, compressed-air tubes, water-mains; telegraph, electric light, and telephone poles; overhead electric tramway poles; high-pressure steam mains for electric light and power installations; Spencer's patent welded flange tubes for high pressures, etc.

Messrs. Poth, Hille, and Co., engineers, merchants, and manufacturers, 27, Leadenhall-street, London, E.C., have just published a new illustrated price-list of "Empress" self-vulcanising jointing and engine-room supplies, "Eagle" high-grade emery and corundum wheels and grinding machinery, etc.

THE JOINT COMMITTEE ON MUNICIPAL TRADING AND CARDIFF.

The following communication has been addressed to us:

On Thursday week at a meeting of the Cardiff Electrical Committee the Town Clerk reported that, having seen the statements made by Mr. Dixon Davies in his evidence before the Joint Committee on Municipal Trading, he had sent the following communication to the Earl of Crewe, the chairman of the committee, and at the same time a copy to Mr. Davies:

"Town Hall, Cardiff, July 30, 1900.

"My Lord,—With regard to the Joint Select Committee on Municipal Trading, of which your Lordship is the chairman, I observe on a perusal of the minutes of evidence taken by the committee that on the 6th inst. Mr. Dixon Henry Davies, solicitor, and secretary of the Chesterfield Chamber of Commerce, was called and examined, and I find on p. 206, paragraphs 2,586, 2,587, and 2,588, that in answer to your Lordship as to the general result of his observations he expressed the opinion that the greatest objection to municipal trading was that it was not so dependable for the supply of the commercial necessities of the community as private trading, and upon being asked by your Lordship to give an instance in support of that opinion he quoted the case of Cardiff, and stated: 'The Cardiff Corporation started the supply of electrical energy some years ago. The works started some time ago, and were not quite up to date, and there were some failures—I believe frequent failures—and the Corporation, after taking the best advice they could get, resolved to extend their plant very materially, and they deposited a Bill for the purpose—for the purpose, that is, of enlargements where necessary—in order to make the electric light works efficient and keep them up to date and supply their customers. But on the Bill being submitted to the ratepayers of Cardiff, a poll was taken, and the poll was circulated with several heads, one of which especially included the expenditure upon the extension of the electric lighting, and the ratepayers by a very large majority refused to proceed with the matter.'

"In answer to the further question of your Lordship as to why the Corporation decided to adopt the rather unusual course of having a poll, he replied: 'I think there has to be a borough fund meeting to sanction the expenditure, and the decision of the meeting was challenged, and a poll was taken as the result of that challenge, so that the fact is that there you have an improvement—the extension of a concern which was extremely desirable from every point of view—from the point of view of the consumers, from the point of view of the owners of the works, the ratepayers, and yet for no reason at all except the capricious change of mind of the ratepayers—and when I say capricious I mean to say it was a change of mind which certainly would not have affected the shareholders in a company—the managers of the works were deprived of the financial resources necessary to keep them up to date.'

"I am desired by the Cardiff Corporation to state, for the information of your Lordship and the Joint Select Committee, that the evidence given upon this point as to what had taken place in Cardiff is entirely misleading, and, indeed, absolutely inaccurate, the facts with reference to electric lighting of the borough of Cardiff being as follows: In the parliamentary session of 1891 the Cardiff Corporation promoted a provisional order enabling them to supply electricity within the borough. That provisional order was in due course confirmed by Parliament, and the Corporation immediately took steps to put the powers thereby entrusted to them into operation, and in the construction of the works they were advised by one of the foremost electrical engineers of the day. The result was that the Cardiff electric light installation was completed in the year 1895, and in accordance with the terms of the order the Corporation were prepared to supply the compulsory area named in their order, and did supply that area, in addition to which they lighted the public streets (in the same area) by electricity. From time to time the Corporation have extended their works, and have laid their mains for some miles outside the compulsory area, and they are at the present time supplying electricity to buildings in several of the suburbs, in addition to which they are continually extending the public street-lighting by electricity. The Corporation have at all times shown themselves most desirous of taking the electrical energy to any part of the borough they may be desired, and with this object in view they have from time to time obtained the sanction of the Local Government Board to the borrowing of large sums of money for carrying out these works; and whereas the cost of laying down the installation in the first instance amounted to £45,000, the actual expenditure incurred by the Corporation up to the present time amounts to £90,000.

"Since the Corporation laid their installation they have never gone outside their resident electrical engineer for advice as to whether they should extend their plant or not. They have never deposited a Bill for the purpose of obtaining power to extend their plant or make enlargements of their works in order to make these works efficient, and keep them up to date to supply their customers. Indeed, they have at the present time all necessary powers to enable them to supply electrical energy in any part of the borough on obtaining the sanction of the Local Government Board to the expenditure. That being so, it of course follows that no poll on the subject of extending the electric light works was taken, and no expression of opinion has been sought or given by the ratepayers in reference thereto. As a matter of fact, whenever the Corporation have gone to the Local Government Board for sanction to the borrowing of money for electric light purposes there has never been any objection by the ratepayers, and none have opposed the same at the local enquiries which the Board have held from time to time.

"Your Lordship will therefore observe that the evidence of Mr. Dixon Henry Davies on the electrical supply of Cardiff is absolutely without foundation. My Corporation desire me to express their very strong disapproval of the action of Mr. Davies, and consider that before presuming to give evidence on a matter of this kind and thus misleading your committee, damaging the reputation of the Cardiff electrical light works, and creating a false impression as to municipal trading in Cardiff, he should at least have taken some trouble to make himself acquainted with the facts.

"Having regard to what has taken place, my Corporation consider it their duty to immediately submit this statement of the actual facts for the consideration of your Lordship and your Lordship's committee, and I am to express the hope that your Lordship will permit this communication to be recorded on the minutes of the Joint Committee.—I am, my Lord, your Lordship's obedient and humble servant, TOWN CLERK.

"The Right Hon. the Earl of Crewe, chairman of the Joint Select Committee on Municipal Trading, Houses of Parliament, Westminster, London, S.W."

The committee decided to have the letter recorded on the minutes.

QUESTIONS AND ANSWERS.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be *ink*) sent in is considered when marking the relative values of these answers. All formulæ must be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter should be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

297. What is the lowest steam pressure at which it is considered economical to use compound non-condensing engines? In a small continuous-current station, 12 hours' run, steam pressure at engine 80lb., what types of engine and dynamo are likely to give best results and run with least noise with load varying from half to full load (1) with floor space limited; (2) unlimited? What should be coal and water consumption per horse-power, feed water between 150deg. and 200deg. F.?—J. S.

Digitized by Google

298. I have a slow-revolution large-unit engine driving a dynamo. The speed of the dynamo is not uniform enough, and I wish to know where to look for and how to remedy this defect.—T.

299. When the load is suddenly taken off an engine in ordinary cases it will race away, but in the case of an engine and dynamo direct-coupled a "dead short" pulls the engine up instantly. Please explain this fully?—W.

300. In designing a polyphase installation, what circumstances would guide you in selecting the number of phases and the frequency to be adopted?—G. R. B.

ANSWERS.

Question No. 291.—I have a line shaft from which are driven various machines. This shaft is driven by two exactly similar motors, one at each end. An ampere-meter is in circuit with each. I note these two never read alike, but vary sometimes by 25 per cent., first one and then the other being the higher. How do you account for this?

[With regard to the answers to question No. 291, there is a delightful lack of real analysis. The resultant condition of the ammeters may be due to a variety of causes, but no one reply really gives the whole of the causes acting; hence for once we give a considerable sample from the MSS. received.—ED. *E. E.*]

Answer to No. 291 (*awarded* 5*s.*).—The facts as stated in this question are not often to be met with in practice, and are very interesting, insomuch that they bear directly upon the theory of shafts. A clear and intelligent explanation of the facts can best be obtained by considering first the general principles for the stiffness as distinct from the strength of shafts, and this we will proceed to do.

If we had a shaft held firmly at one end and subjected to a twisting moment at the other end, and if a line were scribed upon it parallel to the axis of the shaft, and before the twisting force were applied, it would be found that on applying a sufficiently large twisting force that this line was no longer parallel to the axis of the shaft, but took a spiral direction. In general language, the shaft would be said to be twisted. Now, the amount of the twisting of a shaft is dependent upon its diameter, length, and value of the twisting moment. Further, if the angle of twist is less than the limiting angle to produce a permanent twist or set, the shaft will return to its original form after the applied force has been removed. In order to twist a shaft, work has to be expended upon it, and this work is stored up in the twisted shaft. Moreover, the shaft in returning to its original form is capable of giving out this stored energy, and thus doing work. The law governing the stiffness of shafts states that the angle of twist is inversely proportional to the fourth power of the diameter, and directly proportional to the length of the shaft and the twisting moment.

To return now to our question, we have here a shaft twisted in the same direction at each end by the motors, and in the opposite direction by the resistances of the machines. It follows from the above law, if the resultant twisting moment for the various pulleys is at the middle of the shaft, that each end of the shaft will have an equal angle of twist compared with the middle of the shaft. If, however, the resultant twisting moment of the pulleys occurs other than at the middle, the angle of twist will be greatest at that end furthest from the resultant twisting moment. Whilst the pull on the belts remains constant, this does not cause the power given out by the belts to be unequal, as each motor will take up the twist of the shaft at its end and then transmit its share of the total power. In the case in point, the machines must have been thrown on and off indiscriminately, or the power taken off by each machine must have varied greatly. When this is so, it will be readily seen that the angle of twist of the shaft at the motor ends will vary in sympathy with the change of load. Thus the energy being stored up or given out by the twisted shaft, as the case may be, will be continually varying at each end, and therefore the motors will necessarily make an effort to adjust themselves to each new condition. This will lead to a kind of racing action being set up at the motor ends of the shafts, and often the motors will be giving out either too much or too little power, and the result will be as observed.

How this twisting action of the shaft affects the motor power can be best illustrated by considering the action of a spiral spring extended by weights. If such a spring lengthened or shortened, say, 1in. on the application or deduction of 1lb., then if 1lb. were suddenly taken off the total weight on the spring, it would be found that the stored up energy in the spring would cause it at first to recoil more than 1in., though eventually it would settle down to a length 1in. shorter. Similarly, if a sudden increase of 1lb. were made in the total load, it would extend the spring at first more than 1in., though eventually remaining only 1in. longer. This is the kind of action that is going on in our shaft in question. Sometimes the stresses in the shaft will assist the motors to overcome the resistance, and at other times increase the resistance that the motors have to overcome.

It follows, of course, from what has been said that the shaft under consideration is not stiff enough, though probably strong enough, for the power going through it; otherwise the twisting effect would not be sufficient to produce these motor fluctuations.—E. W. T.

Answer to No. 291 (*awarded* 5*s.*).—Assuming that continuous-current shunt-wound motors are used, it appears to me that the following would account for the irregular division of power observed: It does not follow that because "M." has two apparently identical machines, built by the same manufacturer, that they will both have the same magnetisation characteristics; in fact, this is highly improbable, and if these are not identical it is easy to account for the inequalities described. For, let Fig. 1 be the characteristic for machine No. 1 and Fig. 2 that for

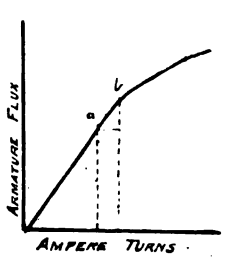

FIG. 1.

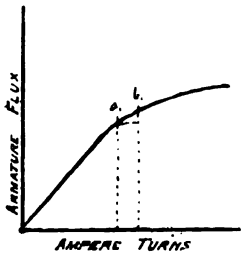

FIG. 2.

machine No. 2, and let the points, b and b_1, be the working points. Now, I presume, "M.'s" experience is that the voltage on his mains is not constant, but varies at least, let us say, 2 per cent. A 2 per cent. drop in volts corresponds to a 2 per cent. drop in ampere-turns, and in case of Fig. 1 considerably more than a 2 per cent. drop in flux, while in Fig. 2 the drop is less than 2 per cent. Machine No. 1 will now tend to revolve faster than machine No. 2, and will, therefore, do more work; hence a larger current flows. The reverse effect will take place when the volts increase, machine No. 2 now doing most work. This effect becomes all the more noticeable owing to the fact that motors are usually worked rather low down on the curve. A less variation in volts than that assumed would easily account for the 25 per cent. variation mentioned, as either machine has only to *try* and run faster than the other, when it immediately takes up more than its proper proportion of the load.—W. P.

Answer to No. 291 (*awarded* 5*s.*).—Supposing a shaft be placed, as in Fig. 1, with the top end firmly fixed, and a twisting movement is applied to the free or bottom end, it will be found that a certain amount of twist can be given to the shaft. If, then, three small sensitive pointers were fixed to the shaft so as to divide the shaft into three equal parts, the amount of twist, as shown by the angles through which the pointers move, would be found to be in the proportions 1 : 2 : 3, where 3 represents the angle through which the lowest pointer has moved; in other words, the angle of twist is proportional to the length of shaft twisted. Further experiment will show that if a twisting movement of a pound-feet produces a twist of $x°$, then a twisting movement of $y\,a$ pound-feet will produce a twist of $y\,x°$, or the twist is proportional to the twisting moment which is applied. Again, experiments will show that for different diameters of shafts, all of the same material, with the same twisting moment, the amount of twist will be inversely as the fourth power of the diameter; while another experiment will prove that with shafts of the same diameter, and

Digitized by Google

with the same twisting moment, the amount of twist will be inversely proportional to the modulus of rigidity of the material.

I have not attempted to prove the above statements, nor to give details of the way in which the experiments should be conducted, as this can be obtained from any good work on mechanics; but a knowledge of these results is essential for the due appreciation of the reason for the disparity in the readings of the two ammeters. Let us now consider for a moment Fig. 2. Here G H B represents a section of the shaft to which a twisting moment is being applied, with the result that the point G, which was formerly at H, has been twisted through the angle G H F to its present position. This angle, in accordance with the result of our first experiment, will be found to get less and less the further we get away from the point where the twisting movement is applied; in other words, an electrician might say that there was a certain lag produced in the shaft, and that this lag was inversely proportional to the distance from the point of application of the twisting moment.

Let us now consider the question more carefully. It is indefinite inasmuch as it does not state whether all the

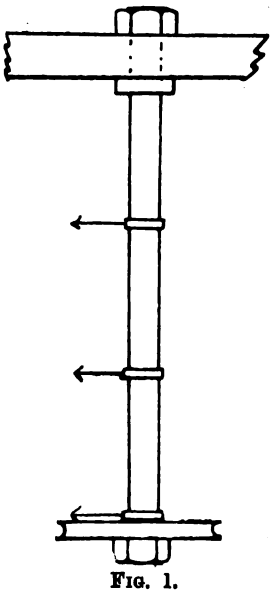

FIG. 1.

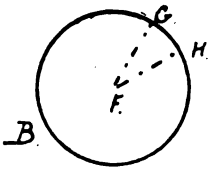

FIG. 2.

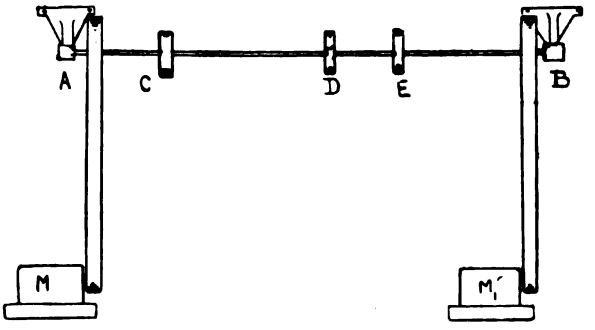
machines require the same horse-power, whether they all are equidistant from each other, or whether the power required by any or all is constant or fluctuating; while as no data is given of the size of shaft, horse-power, etc., no elaborate calculations can be made. Nor is this necessary, as simply a reason for the fluctuations is asked for, as, however, the readings "sometimes vary by 25 per cent.," it is safe to assume that there are large variations in the power required by the various machines. Suppose a shaft were driven by means of a similar motor at either end, and no pulleys or wheels of any sort were fixed to it, with perfect bearings it would be evident that each motor would do half the work, as there is no reason why one should do more than the other; again, if a main pulley is placed in the mathematical centre between the motors, and the power be transmitted from this pulley, each motor should do half the work; but I am afraid that in practice this would not be found to be the case. One bearing would not be so true as the others, or, perhaps, not so well lubricated, and hence would arise a variation in the angles of twist or lag, and one machine would get an undue proportion of the load. Wherever a pulley or wheel is fixed, through which the power is transmitted, the shaft may be considered to be to a certain extent held, and if this position is nearer one motor than the other, the amount of lag in the two portions of the shaft will vary, and the power transmitted by the two portions of the shaft will vary in proportion. If, now, the power is transmitted through various pulleys, and the amount transmitted through each is constantly fluctuating, not only is the shaft held at various points, but also the amount of this "holding" varies in such a manner that while at one moment it is lightly held at one end, the next moment it will be lightly held at another point, and so the work done by each of the two motors will constantly fluctuate, notwithstanding the fact that the total work of the two is nearly uniformly constant. This, I think, will be found to be the explanation of the different readings of the ammeters.—M.

Answer to No. 291 *(awarded* 5*s.).*—The erratic readings of the ammeters in question are probably due to portions of the load being thrown first on to one motor and then on to the other. This effect is brought about by the flexibility of the line shaft, and increased by the fact that the motors are placed at the extreme ends. A shaft transmitting power is subject to two strains—bending and torsion. The bending strain is dependent upon the weight of the shaft itself and of the pulleys mounted upon it, and also, to a certain extent, upon the oblique pull of the belts. For any given shaft the torsion varies directly as the length of shaft and of the arm at which the power is applied, and inversely as the diameter. The case in question is apparently that of a fairly long length of shafting driving machines placed at intervals. Let A B be such a shaft, M and M_1 being the motors, and C, D, and E pulleys for driving various machines. A shaft may be likened to a strongly-coiled cylindrical spring. When the motors are started this spring begins to coil up more closely, the action moving onwards from the driving pulleys to a position midway between the two, so that, considering a very brief space of time, the pulley, D, nearest the mid position is later in beginning to revolve than those nearer to the driving pulleys. With a perfectly steady load and no slip on the belts, the motors would settle down and divide the work equally between them. In workshop practice, however, the load on the shafting is never steady, as some of the machines are either being stopped or started, or else



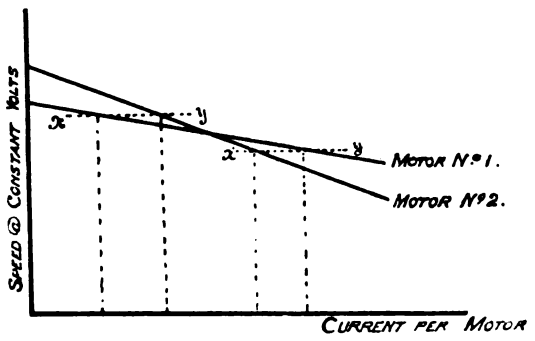
the load on the individual machines varies from time to time. It is possible in this way for a good deal of load to be thrown suddenly on to any one pulley, say that at C. Still thinking of the shaft as a spring, this increase of load on C tends to stop the revolution of the shaft at that point, and has to be overcome by a further coiling up of the spring. It is evident that the motion from pulley A will reach C before that from B, so that at at the instant in question the motor M will be doing more work than that at M_1; hence the difference in the ammeter readings. For every such variation of load the motor nearer to the seat of fluctuation will give a higher ammeter reading than that at the other end of the shaft. The foregoing is an exaggerated way of treating the question, but it enables one to understand clearly the nature of the action going on in a driving shaft.—P. S. T.

Answer to No. 291 (*awarded* 5*s.*).—From the question imagine the two motors are driving the shaft by means of belts or ropes. By this means of transmitting power there is always a certain amount of slip between the belt or ropes and the pulley. Call the motors A and B; they are both running together. First, A slips slightly, and B has to pick up the load; then possibly B slips, and A has to pick up the load. This slip may cause the pulley on, say, A to get hot; which would cause a much greater slip on A, and B would have to do quite 25 per cent. more load. While A having less work to do would soon cool, and B may be getting hot, and so the motors never read alike for any time.—F. C. F.

Answer to No. 291 (*awarded* 5*s.*).—The explanation of this action depends on the circumstances under which the excess current changes from one machine to the other. If, whilst the total load on the shaft remains approximately

Digitized by Google

constant, the load on the two machines, as shown by the ammeters, is found to be constantly varying in an erratic manner—first one and then the other having the larger amount; the effect is almost certainly due to changes of brush contact resistance. Such differences in resistance are particularly liable to occur with carbon brushes through carbon dust getting under them, or through the polish of the surface of the commutator varying. As the brush contact forms a large proportion of the whole ohmic resistance from terminal to terminal, and since the product (ohmic resistance × current) must have the same value for both motors (both running at the same speed and therefore having the same back E.M.F.) a considerable difference in current can easily be produced by this cause. If, on the other hand, the variations of excess current from one motor to the other depends on the actual total load on the shaft—*i.e.*, one motor always having the excess up to a certain load, and the other above that load—the cause is probably a difference in the characteristic curves, or a difference in the position of the brushes in the two machines. Assuming even that the motors are designed to work with the brushes in one fixed position for all loads, it is still quite possible that motor No. 1 has a slightly stronger field than No. 2, due to difference in quality of magnet iron or some such cause. Then in order to make both machines run at the same speed with the same current *on the average*, the brushes of No. 1 may have been fixed in a rather more backward position than No. 2, thus giving greater armature reaction and bringing the two speeds to the same value at about half load. The characteristic for shunt-wound motors



would then be somewhat as in the figure, with the result that at loads below half load motor No. 1 would have considerably less current than No. 2, whilst for higher loads No. 1 would have the excess. A very slight difference in the curves in this respect is enough to give a large difference in current at a given speed, as shown by the horizontal lines, $x\ y$ and $x^1\ y^1$.—Q.

Question No. 292.—If a company supplying at 100 volts charge a dearer rate in the night time than in the daytime, would it be possible to charge two batteries of 55 cells each in parallel in the daytime and put them in series for part of the night time so as to make the meter rotate backwards, and so wipe out part or all of the record of the energy consumed at the dear rate in the earlier part of the night?

Best Answer to No. 292 (*awarded* 10*s.*).—This question opens up several issues—viz.: (1) are electrical meters so constructed as to register in a positive manner if the current is passed through them in one direction, and in a negative manner if the current is passed in the other direction; (2) is it possible to operate cells in the way suggested; (3) would such a method be a financial gain; while (4) a doubt might arise as to the honesty of the scheme.

To take the points in the inverse order, I will pass over the question of the morality with one true anecdote: A man I knew had a gasmeter and a Root's blower. The gasmeter registered up to 2,000,000 cubic feet; when he had used 500,000 he found the meter was not large enough, so had it changed. The men took it out and went for their dinner. The man saw his golden opportunity, and, knowing no reading had been taken, applied his Root's blower to the negative end. Unfortunately for him, his attention was distracted by having to keep a watchful eye open for the approach of the inspector, so that when he finally saw him coming, and had to hurriedly disconnect the blower, he found, to his dismay, that not only had he blown off all his 500,000 cubic feet, but some 250,000 cubic feet in addition, and had to pay a little bill for 1,750,000 cubic feet, whereas a more honest man would have got off for 1,250,000 cubic feet less; and if "J. C. R." adopts his scheme, I should advise him to take precautions not to make the same mistake.

Dealing for a moment with the question of practicability, it is quite possible to operate cells in the way suggested, but whether it would be a financial success is another question. Some time ago the question was asked in this column if it would be advisable to charge secondary batteries during the time of the lower rate for current, in order to use the current from the cells during the time of the heavier charge, and the answers showed that owing to the charges for depreciation, maintenance, and interest, it was only in exceptional cases that this system would pay. Taking the case where the current is supplied at 100 volts, the circuit from the cells would be arranged for 70 or 75 volts, giving a loss of from 25 to 30 per cent. for the operation of charging and discharging the cells; but in this present case the loss will be 50 per cent., as the two batteries will be charged in parallel and discharged in series. It may be mentioned, *en passant*, that each battery will have to consist of considerably less than 55 cells, as such a number will require a terminal pressure of 135 volts for the charging current. Supposing the ordinary current required is 100 amperes; this will be equal at 100 volts to 10 Board of Trade units, and say the price is 3d. per Board of Trade unit, the cost will be 2*s.* 6*d.* per hour. Now, if two banks of cells have to be charged, each with 100 amperes, the cost for current will be 5*s.* per hour, and if these are coupled in series during the time of dearer rate, they can only give back 100 amperes, or 10 Board of Trade units, per hour; and if the dearer rate is double the cheap rate—and it is not likely to be more—it can only just clear itself, and not in any way affect the record of the normal current of 100 amperes required for lighting or power. If the proportion of the rates is, say, as 3 : 1, it might appear as though there would be a saving, but it must be remembered that there will be a heavy *contra* item for maintenance, etc., of the cells, which will more than absorb this saving. Further, it will be found that even if by an arrangement of charging the cells in series groups of 40, and discharging in series groups of 52, leaving the balance of charged cells over for discharge in another series the next day, whereby the loss in the cells might be brought down to 25 per cent., the cost of the cells and their upkeep would be found to eat up more than all the profit.

I think the above will be sufficient to show that it would not be wise to adopt the proposed scheme, and that it will be unnecessary to give a list of what meters are reversible in their action and which are not, for it is self-evident that if the meter is not reversible the whole scheme falls to the ground; but we may conclude that, both on the grounds of morality, self-interest, and practicability, the scheme is not feasible.—M.

Answer to No. 292 (*awarded* 5*s.*).—Though the arrangement mentioned in the question could be used, it would not be the most satisfactory one. The more direct way would be to charge a 50 to 55 cell battery, of the required capacity, during the day at the cheap rate by the help of a small motor-booster. This booster should be capable of supplying the extra 30 or 40 volts required in addition to the supply voltage of 100 in order to fully charge the 100-volt battery. At night, when the lamps have to be lit and the expensive rate comes into force, the supply mains would be entirely disconnected from the installation, and the battery alone would do all the lighting, etc. In this way 100-volt lamps would still be used, so that in case the battery should fail at any time, the lamps could be at once switched on to the supply mains without trouble. If no booster is used the number of cells must be reduced to about 40, so as to be fully charged at 100 volts, and the working discharge voltage of such a battery would be only about 75 volts, and lamps of that voltage would have to be installed, making the system less flexible than with a booster. A comparison of the annual cost of direct supply at the high rate and battery supply with a booster, as described above, will be found in the answers to Question No. 241, in the *Electrical Engineer* for Feb. 23, 1900.—Q.

LIGHT RAILWAYS.

The Board of Trade have recently confirmed orders authorising the construction of light railways in the county of Somerset, between Highbridge, Wedmore, and Cheddar; in the counties of Devon and Cornwall, from Bere Alston Station to Calstock, and the working of a portion of the East Cornwall Mineral Railway as a light railway; in the North Riding of York, from Sinnington to Rosedale; and in the county of Carnarvon, from Snowdon Station to Beddgelert.

Mr. F. Hopwood has held an enquiry into the proposed order authorising the construction of a light railway in the Bourne Valley. A long discussion took place as to clauses for the protection of Lord Portsmouth, and after other objections had been disposed of Mr. Hopwood intimated that he should recommend the Board of Trade to confirm the order and authorise the railway.

The Great Western Railway Company will shortly commence the construction of the light railway which they at first proposed to carry through from Salisbury to Pewsey. The intention is now to construct a light railway from Salisbury to Amesbury, with stations at Durnford and Woodford, the junction with the present Great Western line from Salisbury to Warminster being just beyond Skew Bridge.

At the last meeting of the Great Harwood Urban District Council, the Clerk stated, in connection with the light railway and the electric light joint conference, that those connected with the scheme were quite willing to confer with representatives from that Council with regard to the matter. The question was left in the hands of the Highways Committee.

Mr. Sellon and other representatives of the British Electric Traction Company waited on the Rhondda District Council on Friday last with a view to getting the Council to withdraw its opposition to the proposed light railway scheme for the Rhondda. The Council maintained their resolution to oppose the scheme. A public enquiry will be held by Colonel Boughey on Oct. 27.

At a recent meeting of the Mansfield Woodhouse Council a letter was read from the deputy town clerk of Mansfield stating that the Railway Commissioners, in the draft of the order they proposed to make regarding the electric tramway for the district, had refused to insert nearly all the clauses for the protection of the local authorities, and asked the Council to send a deputation to a joint meeting of the authorities interested.

The Light Railway Commissioners have granted an order authorising the construction of a light railway from Bury St. Edmunds to Attleborough by way of Ixworth, Stanton, Hopton, South Lopham, and Kenninghall. There would be a loop from Stanton to South Lopham, taking in Walsham-le-Willows and Botesdale, and there would be a branch connecting South Lopham with Diss. The estimate put in showed that, including £9,800 for stations, waiting-rooms, etc., the cost of making the railway was £213,302. The cost of the land was estimated at £13,600, contingencies were put down at £21,330, and incidental expenses at £2,767, making a grand total of £251,000.

COMPANIES' MEETINGS AND REPORTS.

WATERLOO AND CITY RAILWAY.

The half-yearly general meeting of the Waterloo and City Railway Company was held last Friday at Waterloo Station, Mr. Wyndham S. Portal presiding.

The **Chairman**, in moving the adoption of the report, said that the accounts showed an authorised capital of £720,000. Up to the end of last June £589,073 had been spent. For the half-year ended June the expenditure had amounted to £15,416, which included £10,922 for the construction of ways and stations, including engineering, and £4,493 for electrical equipment. The estimate of further expenditure on capital account for the current half-year was £15 000, and in subsequent half-year £10,000, making a total of £25,000. This they hoped would not all be required. They had £122 166 available balance of borrowing powers. The revenue account showed that during the past half-year the receipts from passenger fares, after deducting Government duty, were £14 069, compared with £12,815 in the corresponding period of 1899. The working expenses at 55 per cent. were £7,773, as against £6.640 in 1899. The difference between receipts and expenditure not being sufficient to pay the dividend of 3 per cent., the South-Western Railway Company had made up the deficiency of £2,375. They carried over £8,385 to the credit of the net revenue account, which also showed a balance of £155 brought from last half-year's account. The number of passengers for the half-year, exclusive of season-ticket holders, was 1,868.737, compared with 1,715,825 in the corresponding period of 1899, an increase of 152,912. The season-ticket holders on June 30 were 911, as against 747 in the corresponding period. The working company—the South-Western—had begun to run single cars of a new pattern every five minutes during the slack hours of the middle of the day, and they seemed to be much appreciated.

BLACKPOOL AND FLEETWOOD TRAMROAD.

Directors: George Richardson, 98, Westbourne-terrace, Hyde Park, London, W. (chairman); Richard Henry Prestwich, Homeleigh, Park-lane, Higher Broughton, Manchester (deputy-chairman); Robert Breese Barningham, 41, Victoria-buildings, Manchester; Robert Slater Boddington, Wynslade, St. Annes-on-the-Sea; John Greenwood, 1, Marsden-street, Manchester; George Readman, 9, Moray-place, Edinburgh. Manager and secretary: John Cameron.

Report of the directors (with abstract of accounts) to be submitted to the proprietors at the ordinary half-yearly general meeting to be held on Aug. 23, 1900, at the Company's offices, the terminus, Fleetwood, at 2 p.m.:

Including the sum brought forward from last half-year, the balance of profit, after providing for debenture interest, is £4,265. 5s. 11d., and the directors recommend a dividend at the rate of £4 per cent. per annum, which will absorb £3,000, writing off £100. 19s. 1d. from the cost of application to Parliament for further powers under Act 1898, £169. 7s. 6d. from preliminary expenses, and a sum of £500 for depreciation, leaving a balance of £494. 19s. 4d. to be carried forward to the current half-year. The number of passengers carried during the half-year was 660,006; the gross receipts £10,125. 17s. 2d. Owing to the fact that the early part of the year was unfavourable for the traffic, and the season three weeks later than that of 1899, the number of passengers carried and the gross earnings are considered satisfactory by the directors.

CAVEHILL AND WHITEWELL TRAMWAY.

The directors of this Company, having received a proposal from the British Electric Traction Company for the conversion of the Company's tramway to electric traction, after careful consideration unanimously decided to recommend the shareholders to agree to the proposal.

An extraordinary meeting of the shareholders was held last week, the chair being occupied by the **Venerable Archdeacon Smythe, M.A.**, who briefly explained the purpose for which it had been summoned, and called upon Mr. Nance to submit a resolution on the subject.

Mr. Nance then moved the following resolution: "That the directors be authorised to negotiate and carry out an agreement with the British Electric Traction Company in the terms of Mr. Frank Kerr's letter written on their behalf, and proposing to give the shareholders of this Company the right to convert their 15,000 ordinary shares into 6 per cent. cumulative preference shares at par upon certain terms therein contained.' In moving the resolution, Mr. Nance pointed out several reasons why the directors thought the proposal ought to be accepted.

The resolution was unanimously adopted.

LIVERPOOL OVERHEAD RAILWAY.

The twenty-fourth half-yearly meeting was held on Tuesday in Liverpool.

Mr. William Forwood, chairman of the Company, presided, and said that during the last seven years 58 million passengers had been carried, the trains having run almost five million miles. The receipts were £38,022, an increase of £1,530 on the receipts of the same period last year; £25,113 had been spent, £189 more than last year. They had to pay in interest on mortgage £3,400, leaving the amount available for dividend £14,402. They intended to pay that day a dividend for their preference shares at the rate of 5 per cent. per annum, absorbing £3,000, and they recommended the payment of an increased dividend at the rate of 3 per cent. per annum upon the ordinary shares, which would amount to £6,750. This would leave them a balance to carry forward of £4,452, against a balance last year of £4,320. The Chairman observed that they still held the record of punctuality; 97·3 of their trains had during the past half-year been on time. That was their best record for four years, their next best record being in the year 1896. It was proposed to increase the speed of the trains, and make the journey of 6½ miles with 15 stoppages in 20 minutes. It was also proposed to make use of the line at night, when the railway was eight hours idle, in conveying minerals. The above recommendation of dividends was proposed and carried.

STOCKPORT TRAMWAYS.

The twenty-third ordinary general meeting of the Stockport and Hazel Grove Carriage and Tramways Company was held last week.

Mr. J. D. Penney (chairman), who presided, moved the adoption of the accounts and directors' report.

Mr. Loose seconded, and the resolution was carried without comment.

The report was as follows: "We herewith submit our statement of accounts for the past half-year, which shows a profit, after placing £100 to reserve fund, of £631. 16s. 3d., which, together with £676. 4s. 10d. brought forward from last half-year's account, make a balance of £1,308. 1s. 1d. available for dividend. Out of this amount we propose to pay a dividend at the rate of 10 per cent. per annum, which will absorb £637. 10s., and carry £670. 11s. 1d. to next account.

Dr. Thomas Moore was re elected a director.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ilford.—The Urban District Council invite offers for free wiring. Tenders by 29th inst.

Luton.—The Electric Lighting Committee invite tenders for the supply and erection of meters.

Lincoln.—The Town Council invite tenders for wattmeters and demand meters. Tenders by Sept. 14.

Hamburg.—Two 30-ton electric cranes are required. Enquiries may be made at the Town Hall. Tenders by Sept. 10.

Warrington.—Tenders are required by the Corporation for installation of mains and fittings at town hall and market.

Worksop.—The Urban District Council invite tenders for the erection of electricity supply works in Canal-road. Tenders by 27th inst.

Plumstead.—The Vestry invite tenders for the supply and erection of various plant and machinery for electricity works. Tenders by Sept. 15.

Newport (Mon.).—The Guardians invite tenders for a complete installation of electric light at the new workhouse, Stow-hill, Newport. Tenders by 22nd inst.

Stockport.—The Tramways Committee invite tenders for 20 double-deck tramcars, complete with electric equipment for overhead traction. Tenders by Aug. 31.

Aberdeen.—The Town Council invite tenders for the supply of steel tiebars, fishbolts, and nuts. Tenders by 24th inst. Details in our advertisement columns.

Newcastle-upon Tyne.—The New Tramways Committee invite tenders for conduits and holes for poles. Tenders by 31st inst. Details in our advertisement columns.

Manchester.—The Tramways Committee invite tenders for the supply of cast-iron bases for tramway poles. Tenders by 25th inst. Details in our advertisement columns.

Fulham.—The Vestry invite tenders for wiring the town hall, Walham Green, for the electric light. Tenders by 24th inst. Details in our advertisement columns.

Nelson.—The Corporation invite tenders for the supply of a 200-kw. steam dynamo for their electricity works. Tenders by Sept. 8. Details in our advertisement columns.

Southampton.—The Harbour Board invite tenders from crane builders for one 30cwt. portable electric wharf crane. Tenders by Sept. 10. Details in our advertisement columns.

Rochdale.—The General Purposes Committee invite tenders for the wiring and fittings required in connection with the electric lighting of the town hall. Tenders by 22nd inst.

Glasgow.—The Corporation invite tenders for the reconstruction of the Glasgow tramways, and the construction of new tramways as detailed in specification. Tenders by 24th inst.

Leeds.—The Tramways Committee invite tenders for the erection of a new boiler-house (all trades except ironfounders') at the generating station, Crown Point, Leeds. Tenders by 21st inst.

Shipley (Yorks).—The Council invite tenders for steam and exhaust pipes, storage battery, switchboard and connections, and cables. Tenders by 27th inst. Details in our advertisement columns.

Cardiff.—The Corporation invite tenders for the supply and delivery and fixing of sundry pipes, feed-water heaters, etc., at the Corporation electricity works, Eldon-road, Cardiff. Tenders by Aug. 31.

Cupar Fife.—Tenders are invited at once for an electric lighting installation at the Fife and Kinross District Lunatic Asylum, about 800 lights. Apply to Mr. D. Osborne, clerk to the Board, Cupar Fife.

Horton (Surrey).—The Asylums Committee of the London County Council invite tenders for the installation of boilers, engines, dynamos, etc., at the Horton Estate, Epsom, Surrey. Tenders by Sept. 22.

Newcastle-on-Tyne.—The Corporation invite tenders for the laying down in Newcastle of about five miles of double-line tramway, the rails and fastenings and the poles being supplied by the Corporation. Tenders by Aug. 22.

Manchester.—The Electricity Committee invite tenders for the work and materials in the trades of concretor, stonemason, and ironfounder required in erection of the electricity generating station, Bloom-street. Tenders by 21st inst.

Southampton.—The Guardians invite tenders for the erection and completion of electrical plant and installation for the lighting of the new workhouse infirmary, Shirley Warren. Tenders by Sept. 11. Details in our advertisement columns.

Aberdeen.—The Corporation Tramways Committee invite tenders for the supply of steel poles, bases, and brackets for extensions of their overhead system of tramways. Tenders by 25th inst. Details in our advertisement columns.

Vienna.—The Government Railways invite tenders for various supplies for lighting their stations, etc., in the districts of Vienna, Linz, Innsbruck, Villach, Triest, Pilsen, Prag, Olmütz, Krakau, Lemberg, and Stanislau from Oct. 1, 1900, to Sept. 30, 1901. Tenders by 30th inst.

Aberdeen.—The Electric Lighting Committee invite tenders for a twelvemonth's supply of paper or fibre insulated lead-covered feeder, distributing and service cables, electricity meters, and house main fuse boxes. Tenders by 28th inst. Details in our advertisement columns.

Hackney.—The Electric Lighting Committee invite tenders for condensing plant, cooling apparatus, pipework and valves, feed pumps, switchboard and boosters, public arc lamps, meters, travelling crane, and workshop equipment. Tenders by Sept. 12. Full particulars in our advertisement columns.

Salford.—The Corporation invite tenders for the supply, delivery, and erection of the following plant: lighting switchboard, traction switchboard, and balancing transformers at their new electricity works, Strawberry-road, Pendleton. Tenders by Sept. 3. Details in our advertisement columns.

Whitby.—The Council invite tenders for the following plant: two water-tube boilers, pumps, condensers, pipes, etc., two steam dynamos, balancer, and boosters, switchboard and connections, battery, travelling crane, and cables, arc lamps, etc. Tenders by Sept. 3. Details in our advertisement columns.

Portsmouth.—The Corporation invite tenders for the supply, delivery, and erection of the whole of the plant and apparatus necessary to completely equip for electric traction their proposed power station at Vivash-road, Fratton-grove, Portsmouth. Tenders by Sept. 4. Details in our advertisement columns.

Grimsby.—The Corporation invite tenders to specification for the supply and delivery, in connection with the electric lighting of the borough, for additional steam dynamos: Section 1, engine; Section 2, dynamo; and extension of switchboard for dynamo No. 7, and traction work. Tenders by 18th inst. Details in our advertisement columns.

St. Petersburg.—The Posts and Telegraphs Department invite tenders for the working of the telephone systems in St. Petersburg, Moscow, Warsaw, Odessa, and Riga for 18 years from Nov. 1, 1901. Tenders by Aug. 28. All necessary particulars may be examined on personal application at the Imperial Russian Financial Agency, 107, Cromwell-road, London, S.W., on Mondays, Wednesdays, and Fridays, from 2 to 4 p.m.

Aberdeen.—The Town Council invite alternative tenders for the supply of 650 tons steel girder straight-track tramway rails, weight about 100lb. per lineal yard; 150 tons steel girder curve-track rails, weight about 104lb. per lineal yard, in standard lengths of 60ft. or 45ft., as may be decided; also for 60 tons fishplates, weight about 75lb. per pair. Tenders by 24th inst. Details in our advertisement columns.

Hanley.—The Electric Lighting Committee invite tenders for the supply, delivery, and erection complete of two Lancashire boilers and fittings, including steam receiver; water-tank, girders, and pumps; fuel economiser, with engine or motor; smoke chimney, exhaust fan, with engine, etc.; feed-water heater; forced-draught fittings, firebars, or other appliances to boiler furnaces; and coal conveyor and bunkers. Tenders by 25th inst.

Worthing.—The Corporation invite tenders for the supply and erection of the following plant: (1) three 96-kw. steam dynamos (vertical enclosed high-speed engines); (2) two boilers of the dry-

Digitized by Google

back marine type, with fittings, etc.; (3) steam and exhaust, drain and other pipes, in engine and boiler house, pumps, condensing plant, etc.; (4) cast-iron manhole covers; (5) cast-iron arc lamp posts; (6) stoneware casings; (7) cable work; (8) arc lamps; (9) storage batteries; (11) balancing transformers and motor-generators; (12) economiser; (13) five-ton overhead engine-room travelling crane. Tenders by Sept. 3.

Fenton (Staffs).—Tenders are invited for works in connection with the construction of a single line of railway (2ft. 6in. gauge) from Waterhouses to Hulme End, Staffordshire (about eight miles two furlongs), and incidental works connected therewith, for the Leek and Manifold Valley Light Railway Company. Plans, specifications, bills of quantities, and forms of tender may be inspected at the offices of the company's engineer, Mr. Joseph Forsyth, Heron's Cross, Fenton, Staffs, on and after Aug. 4, and copies of same may be obtained from him. Sealed tenders must be sent to Mr. Edward Challinor, secretary, Leek, by Sept. 1.

London, W.—The Central Electric Supply Company invite tenders for the supply, delivery, and erection of (Specification 2A) dry-back marine boilers, 11ft. 6in. diameter and 14ft. long, gangways, feed and drain pipes, etc., complete, as required for each of three blocks of boilers. Each or all of the blocks can be tendered for, each block containing six boilers. Tenders are also to be submitted for mechanical stokers, with the shafting and gearing for driving them. Alternative tenders are invited for (Specification 2B) water-tube boilers as an alternative to the dry-back marine boilers, including the mountings, feed and drain pipes, etc. Copies of the specifications, with forms of tender, drawings, and general conditions, can be obtained from the General Manager, 19, Carnaby-street, Golden-square, W., on payment of £3. 3s., to be returned on receipt of a bona fide tender. Specifications and drawings can be seen at the office of Prof. Kennedy, 17, Victoria-street, S.W. Tenders, on the prescribed form, endorsed on the outside "Electric Plant—Tender to No. — Specification," must be sent to Mr. F. J. Walker, general manager, before 10 a.m. on Aug. 20.

RESULTS OF TENDERS.

Brookwood Asylum.—The tender of Messrs. Shalders and Davis, Southampton, for electric light plant and wiring, at £5,600, has been accepted.

Sheffield.—The Corporation have accepted the tender of the Electric Construction Company, Wolverhampton, at schedule rates, for 12 months' supply of transformers.

Huddersfield.—The Corporation have accepted the tender of R. W. Blackwell and Co., Limited, for the overhead equipment of two short sections of tramways (total length about 2 miles 300 yards).

Blackpool.—Tenders for electrical appliances have been placed with the following firms; Leeds Steelworks, rails; Askham Bros. and Wilson, points and crossings; L. Cooper, patent jointing materials for tramways; Lowther Bros., trolley poles, storage battery, boosters, and switchboards; St. Helens Cable Company, cables and trolley wires. They were for the Marton tramways, and the total amount will be £27,000.

Nelson (Lancs.)—The following tenders have been received for the electric lighting at the Baptist Chapel, Carr-road:

Alliance Company, London	£468
W. Smith	248
Duckinfield	240
Hanwell	234
National Electric Wiring Company (accepted)	170

BUSINESS NOTES.

TRACTION.

Southport.—Since the electric tramways were opened on July 18, the receipts have amounted to £750.

Fiume.—A dynamite cartridge was exploded under a carriage of the city electric railway on the 9th inst., but without causing any damage.

Ince.—The District Council are considering the subject of purchasing the tramways in their district. They have six months in which to do so.

Newport.—At Tuesday's meeting of the Town Council the supply of electric motive power and the construction of a tramway up Stow-hill were discussed.

Stretford.—The District Council have confirmed the report of the Electricity and Tramways Committee as to the terms of agreement with the Manchester Corporation.

Newcastle.—At a meeting of the Tramways Committee of the Newcastle Corporation, it was announced that the erection of the new car-sheds at Byker would be proceeded with on Monday next.

North Metropolitan Tramways Co.—At the sixty-first half-yearly meeting of this Company, Mr. G. Richardson, who presided, stated that the adoption of electric traction depended on the London County Council, who had not yet made experiments on their line.

Bournemouth.—At a recent meeting of the Town Council a motion was carried for the purchase of land for the site of the future power-house for the electric tramways. The plans and estimates necessary to obtain the sanction of the Board of Trade are being prepared.

Prestwich.—The Electric Lighting and the Tramways Bill having received the Royal assent, the Council are now only waiting for the completion of the agreement with the Manchester Corporation.

Gosport.—The District Council have informed Mr. A. W. White that at present they were not prepared to enter into any negotiations to acquire the tramway or to enter into any arrangement with the company to promote a Bill for the extension and conversion of the undertaking.

Dublin United Tramways Co.—From the Company's traffic returns for the last week we learn that the mileage worked electrically is 43 miles, only one mile now remaining being worked by horses, as against 18 miles electrically and 26 miles by horses for the corresponding period last year.

Morecambe.—Plans and estimates are being prepared by the manager of the Morecambe electricity works for the application of overhead traction on the Morecambe Tramway Company's lines, which are at present worked by horse traction. It is proposed to erect an electric light sub-station at Bare.

Derby.—As already noted in our last issue, the Town Council have carried the resolution recommending the adoption of the tramway scheme. This will involve an estimated cost of £200,000. This scheme is to reconstruct the lines for electric traction, and also to extend them. The site proposed for the power-house, etc., is next to the electric light station.

Dewsbury, Batley, and Birstall Tramways Co.—It was stated at the yearly meeting of this Company on the 9th inst. that the alteration from a 15 to a 10 minutes' service of cars had resulted in 15 months in a loss of nearly £500. The shareholders present voted in favour of the 10 minutes' service being discontinued, and suggested that halfpenny stages be tried for three months. Both matters will be considered by the directors.

Leamington and Warwick Tramways.—A provisional order for the working of the tramway by electric traction in the borough of Warwick has been obtained, and negotiations are pending with the Corporation of Leamington with a view to acquire a similar order for that borough. When the requisite legislative powers have been obtained, the arrangements for converting the line into an electric tramway will involve the winding up of the existing company.

Bradford Contracts.—The Tramways Committee of the Bradford Corporation on the 9th inst. considered reports on the allegations as to the deviation from the specifications in the contract for the electrical equipment of the Corporation tramway extensions. A resolution was adopted expressing the committee's belief that in every case the substituted apparatus and materials were at least fully equal to those originally specified, and in many cases an improvement. The committee's action was subsequently confirmed at a meeting of the Finance and General Purposes Committee.

London United Tramways.—The whole of the lines from Shepherd's Bush to Acton; from Shepherd's Bush, *vid* Goldhawk-road, to Kew Bridge; and from Hammersmith-broadway, through Chiswick, *vid* Kew Bridge and Brentford, to Hounslow, are now complete in every detail, but a difficulty has arisen which is causing delay. At the instance of the Treasury a clause was inserted requiring the Company to take such precautions as were deemed necessary to prevent disturbance of the magnetic recording instruments at Kew Gardens Observatory, and the negotiations, which have been in progress for some time, have not yet resulted in a decision.

Warrington.—At a recent meeting of the Electric Lighting Committee, the Tramways Sub-Committee reported that the Bill for confirming the Warrington Corporation (Tramways) Order, 1900, was then about to receive the Royal assent. The sub-committee further stated that all the tramways proposed to be constructed by the Corporation had been allowed. They called attention to the provisions of the Tramways Act, 1870, which require the tramways to be commenced within 12 months and completed in two years. Having regard to the difficulty of carrying out so large a scheme of tramways within the time stated, it may be found advisable to apply for an extension of time in respect to some of them.

Bolton.—An estimate was submitted by the borough engineer to the Corporation last week of the cost of carrying out the relaying of the tramways, which was approved, and it was decided to apply to the Board of Trade for sanction to borrow the sum of £87,500 needed to relay the whole of the track. The engineer also reported terms with the Barrow Hematite Company for supplying 150 tons of rails, with fishplates. The chairman, vice-chairman, and general manager were deputed to interview the Farnworth District Council as to the electrical equipment of the Farnworth tramways, which is considered unsatisfactory. It was decided that, if desired, the pillars in the centre of the streets be drilled and used for electric lamp purposes.

Trams in the Lake District.—Some people have still queer notions with regard to electric tramways. We find the following in the *Daily Telegraph*: "Objections having been raised by the Bowness District Council to the tramway scheme of the British Electric Traction Company, a modified proposal has been presented, which the Council, by a majority of one, have accepted. There was strong opposition to the scheme on general grounds. One member expressed his belief that by lending itself to the convenience of the excursion element the scheme would drive away the better class of residents, while another asserted that if the tramway was introduced into the narrow roads of Bowness traffic accidents would increase by 50 per cent., and pedestrians, cyclists, and horses would be floundering about in every direction."

Digitized by Google

Burton-on-Trent.—At a conference between a deputation of the Burton Corporation and the promoters of the Woodville and Swadlincote light railways, on the 10th inst., Mr. Smith (of the firm of Messrs. Green, Smith, and Hood, of Liverpool), on behalf of the promoters, explained their scheme, which, he said, was for a light railway of standard gauge running from Woodville, through Swadlincote and Newhall, to Burton-on-Trent. Considerable discussion ensued, and it was intimated that there was a possibility of an arrangement whereby the whole of the lines on both sides of the river might be worked as one system. As to the question of motive power, Mr. Smith said he was firmly of opinion that the overhead system of electric traction was the only one possible.

Glossop.—At the quarterly meeting of the Town Council last week the question of constructing electric tramways in the borough was discussed, and an agreement was read proposing to transfer the tramways order to Edmundson's Electricity Corporation, Limited, to whom the electric lighting order for the borough had already been transferred. The Town Clerk said the Council had power to purchase on a fair valuation at any period of seven years, but they could not purchase the tramways without the electric light scheme. The overhead system would be adopted, and the cars would run from the Queen's Arms, Old Glossop, to the Palatine Hotel, Hadfield, a distance of four miles. The maximum fare would be 1d. per mile, and 2d. for the whole distance. It was decided to affix the common seal to the agreement and a deed of guarantee.

Waterloo-with-Seaforth.—The proceedings of the Tramways Committee, which were passed at the Urban District Council meeting last week, contained a complaint from a resident in Crosby-road with regard to the noise proceeding from the points on the electric tramway route. The contractors have been applied to, and have replied "that it very frequently happens that when a tramway begins working someone or other objects to the click of the points, but after a very short time this dies out. We would suggest putting in a lighter spring so as to reduce the click, or else inserting a thin piece of leather or a thin sheet of lead between the point of the tongue, which is done on some tramways, but, as a rule, very little notice is taken of the matter, and scores of tramways do not insert anything whatever." The suggestion is to be acted upon.

Battle.—The Urban District Council have received from the solicitors to the Hastings tramways an answer to a communication from the clerk stating that the Council would be prepared to oppose the application for a provisional order to supply electricity in the district, if the order meant that the company would have the power to supply the whole district at any time. The letter said: "The view of the company is that the whole of your district could be more efficiently and economically lighted from the generating station which will be erected in connection with the system of tramways which the company have just been authorised to erect in Bexhill and Hastings, but if there are any portions which could be more efficiently lighted from other sources, perhaps you will be so good as to indicate them, so that we may send the information to the company." The matter was discussed last week, and finally allowed to stand over.

Ayr.—At Monday's meeting of the Town Council it was reported that an offer of 3s. per pole for ground at Bellesleyhill, Prestwick-road, to be used as a car station for the tramways, had been accepted. The question of a separate generating station had been again under the consideration of the committee, and it had been decided to accept the Electric Lighting Committee's offer to supply energy at the rate of 1½d. per unit for the first 200 000 units, and 1d. per unit above that quantity, annually, the Lighting Committee to pay the tramway undertaking compensation at the rate of 9d. per car mile for any stoppages arising from deficiency or want of current. The question of the appointment of Mr. A. J. Fuller, the burgh electrical engineer, to carry out the electrical part of the undertaking had been under consideration, but no definite decision had been arrived at. Tenders for 10 cars with complete electrical equipment are to be invited.

Life-Guards.—At the inquest held on the 10th inst. on the body of a child which was killed by being run over by a tramcar at Halifax, the jury returned a verdict of accidental death, and added that in their opinion no blame whatever could be attached to the driver. During the evidence Mr. Spencer, the tramway manager, stated that although the life guard was only 1¾in. above the ground the child got under it all the same. There had been three or four instances in Halifax where the life-guard had picked up older children. There was, practically speaking, no life-guard yet in existence that would prevent this sort of thing. There were a good many in the market, but the Board of Trade had not yet seen a life-guard to their satisfaction. The solicitor also observed that in Bradford they had spent hundreds of pounds in getting a good life-guard, but unsuccessfully. It seems to us that not long ago a first prize was awarded in the competition of life guards at the Tramways Exhibition at the Agricultural Hall. An inquest was held at the Swansea Hospital on Friday on the body of Howard Stafford Rees, a boy of 13, who was run over by an electric car from which he had jumped off on Wednesday, and died at the hospital on Friday morning. The jury, after hearing the evidence, returned a verdict of accidental death, absolving the conductor and driver from blame, but adding a rider that the double cars should be guarded with guards in front of the hind wheels, which appeared to be somewhat exposed.

Sunderland.—At the Town Council meeting last week a report was submitted by the Tramways Committee recommending that arrangements be entered into with the contractors to construct the route *vid* Villette-road on to Christ Church upon the terms of their existing contract, the work to be done along with the Suffolk-street route; that children from three to twelve years of age be permitted to travel on the cars at half fare—this to apply to all sections; and that notices be served upon owners and occupiers of property in Vine-place, and application made to the Board of Trade to lay a double line of tramways in Vine-place, according to plan submitted to the meeting, the like in High-street West, near Londonderry Hotel, according to plan submitted to the meeting. A motion to adjourn the matter for a year having been rejected, the above report was carried. On Wednesday afternoon the first section of the Sunderland Corporation electric tramways was officially opened. The route completed is that between Christ Church and Roker, and the trials which have been made during the past few days have proved eminently satisfactory, everything working smoothly. The Sunderland Corporation Act of 1899 gave the Council power to construct 23 miles of single track, and of this it was decided to equip at once 12½ miles. On the advice of Mr. J. F. C. Snell (borough electrical engineer) it was decided to adopt the overhead system of tramways, and the contract for the entire reconstruction of the old lines, with the addition of the route mentioned, the electrical equipment and the first instalment of cars was let to Messrs. Dick, Kerr, and Co., of London and Kilmarnock, for about £126,000. In Fawcett-street rosettes are fixed to the house fronts. In the wider streets centre poles are erected with arms on either side, and in the other parts of the routes the wire is suspended from side bracket poles, and the trolley wire is hung at a height of 22ft. from the roadway. As the current is to be supplied by the Lighting Committee of the Corporation, more generating plant has been laid down. Four Galloway boilers, 28ft. by 8ft. 6in., have been put in, with mechanical stokers and economisers, and special elevating machinery to save handling of the coal. In the engine-room there are three new 450 i.h.p. steam dynamos, each engine being of the three-crank compound type, the generators having been made by the Sunderland Forge and Engineering Company, Pallion. The Corporation have ordered three different types of cars. One kind possesses only a single deck, as there is a low bridge on one of the routes. Six of the vehicles will be double deckers, carrying 68 passengers; these are for the Roker route. The remainder are double-deck outside-seat single-truck cars, which have accommodation for 56 persons. Each car is driven by two 25-h.p. motors, which are capable of propelling the car up an incline of 1 in 12 at a speed of eight miles an hour, and are equal to the task of starting the car, fully laden, from rest up a similar incline. The tramway contractors have just been instructed to proceed with the Villette-road extension.

LIGHTING AND GENERAL.

Motor Club.—Efforts are being made to start a local motor club at Newcastle.

Rochdale.—The lighting of the workhouse will probably be completed in six weeks.

Ryl.—The Urban District Council have obtained permission to borrow £15,250 for electric lighting.

Alnwick.—The Urban District Council are conferring with two electrical supply companies, and also with a refuse-destructor company.

Dorchester.—The Town Council will apply to the Board of Trade for a provisional order to enable them to light the borough with electricity.

Luthrie.—The Post Office authorities are now laying the telegraph to Luthrie, and hope to have the communication complete by the end of the month.

Shrewsbury.—At the recent quarterly meeting of the Town Council a very considerable extension of the electric lighting of the public streets was approved.

Bolton.—The appointment of borough electrical engineer, at a salary beginning with £500, rests between Messrs. A. A. Day, J. A. Jeckell, H. T. Street, and W. R. Wright.

Whitehaven.—It is reported that the new buildings in connection with the extension of electric light station will be ready for the reception of the machinery in about a month.

Braintree.—The Urban District Council are not in favour of the North British Electricity Supply Company's suggestion to obtain a provisional order to supply the Braintree district.

Dairy.—A letter from the North British Electricity Supply Company is before the Northern District Committee for consideration, with a recommendation that steps be taken to oppose any monopoly.

Bury.—It is proposed that eight arc lamps of 2,000 c.p. each be erected in the central part of the town. Plans are to be submitted with a view of ascertaining the cost of building an accumulator-house.

Bognor.—Some of the Guardians desire electric light to be installed at the workhouse. Recently a motion that the Visiting Committee should consider the matter was brought forward, but was defeated.

Beverley.—The Town Council have decided to apply for a provisional order empowering the Corporation to supply electricity within the borough, and Mr. Gibbings has been instructed to prepare plans.

Change of Address.—The offices of the electric lighting department of the Hull Corporation have been removed to the electric lighting station, Sculcoates-lane, Hull, and the Dagger-lane offices have been closed.
